With humility and reverence, this book is dedicated at the lotus feet of the Holy Mother

Sri Mata Amritanandamayi Devi

“Today’s world needs people who express goodness in their words and deeds. If such noble role models set the example for their fellow beings, the darkness prevailing in today’s society will be dispelled, and the light of peace and non-violence will once again illumine this earth. Let us work together towards this goal.” —Mata Amritanandamayi Devi
Preface to the Sixth Edition

We are glad to present the sixth edition of the *Textbook of Biochemistry for Medical Students*. With this sixth edition, the textbook is entering the 16th year of existence. With humility, we may state that the medical community of India has warmly received the previous editions of this book. Many medical colleges and universities in India have accepted it as one of the standard textbooks. We are happy to note that this book has also reached in the hands of medical students of neighboring countries of Nepal, Pakistan, Bangladesh, Sri Lanka, etc. and also to distant countries in Africa and Europe. Apart from the medical community, this book has also become popular to other biology group of students in India. In retrospect, it gives immense satisfaction to note that this book served the students and faculty for the past one and half decades.

At this time, a revision of the textbook has become absolutely necessary for two reasons. Firstly, the Medical Council of India has revised the syllabus for biochemistry, especially enhancing the topics on Clinical Biochemistry. Accordingly, we have made elaborate changes in the order of chapters, old chapters on clinical chemistry have been extensively updated and clinically relevant points were further added. Secondly, rapid progress has been made in the area of molecular biology during past few years, and these advances are to be reflected in this book also. The major change in this sixth edition is that advanced knowledge has been added in almost all pages, a few sentences were added here and there in almost all pages; sometimes, a few pages are newly incorporated; while it became necessary to include a few new chapters also.

From the first edition onwards, our policy was to provide not only basic essentials but also some of the advanced knowledge. About 30% contents of the previous editions were not required for a student aiming for a minimum pass. A lot of students have appreciated this approach, as it helped them to pass the PG entrance examinations at a later stage. However, this asset has paved the way for a general criticism that the extra details are a burden to the average students. Especially when read for the first time, the student may find it difficult to sort out the essential minimum from the desirable bulk. So, in the fifth edition, we have promised that we shall make two different books, one for MBBS and another one for postgraduate courses in Biochemistry. Thus, the content has been reduced substantially in the last edition. But, due to various reasons, most of which beyond the control of the authors, the postgraduate book could not be published. This led to the criticism that the content is sub-optimal. Many PG students were enquiring about the advanced book. The advanced students felt that they were neglected. This 6th edition is a compromise. Advanced topics are given in small prints. In essence, this book has three components; rather this book is composed of three books. The bold printed areas will be useful for the students at the time of revision just before the examinations; regular printed pages are meant for an average first year MBBS student (must-know areas) and the fine printed paragraphs are targeted to the advanced students preparing for the PG entrance (desirable to know areas). The readability has been markedly improved by increasing the font size in the regular areas.

Essay and short notes questions, problem solving exercises, viva voce, quick look, multiple choice questions (MCQs) are given as a separate book, but free of cost. These questions are compiled from the question papers of various universities during the last decade. These questions will be ideal for students for last-minute preparation for examinations.

A textbook will mature only by successive revisions. In the preface for the first edition, we expressed our desire to revise the textbook every 3 years. We were fortunate to keep that promise. This book has undergone metamorphosis during each edition. Chemical structures with computer technology were introduced in the second edition. Color printing has been launched in the third edition. The fourth edition came out with multicolor printing. In the fifth edition, the facts were presented in small paragraphs and that too with numbers, so as to aid memorization. In this sixth edition, figures are drastically increased; there are now about 1,100 figures, 230 tables and 200 boxes (perhaps we could call it as Illustrated Textbook of Biochemistry), altogether making the book more student-friendly. The quality of paper is also improved during successive editions.

We were pleasantly surprised to receive many letters giving constructive criticisms and positive suggestions to improve the textbook. These responses were from all parts of the country (we got a few such letters from African students also). Such contributors include Heads of Departments, very senior professors, middle level teachers and mostly postgraduate students. We have tried to incorporate most of those suggestions, within the constraints of page
limitations. In a way, this book thus became multi-authored, and truly national in character. This is to place on record, our deep gratitude for all those “pen-friends” who have helped us to improve this book. The first author desires more interaction with faculty and students who are using this textbook. All are welcome to communicate at his e-mail address <dmvasudevan@yahoo.co.in>

The first author is in the process of retirement from active service, and would like to reduce the burden in due course. A successful textbook is something like a growing institution; individuals may come and go, but the institution will march ahead. Therefore, we felt the need to induce younger blood into the editorial board. Thus, a third author has been added in this sixth edition, so that the torch can be handed over smoothly at an appropriate time later on.

In this connection, I would like to introduce the young author, Dr Kannan Vaidyanathan. He has teaching experience of 15 years. He took MD in Biochemistry from Kerala, and done extensive research at the Indian Institute of Science, Bengaluru, Karnataka. He has also visited many advanced laboratories world over, and presented papers in different international conferences. He has many publications to his credit. He is now Clinical Associate Professor, Department of Biochemistry, and Head, Metabolic Disorders Laboratory, Amrita Institute of Medical Sciences, Kochi, Kerala.

The help and assistance rendered by our students in preparing this book are enormous; the reviews collected by Dr Sukhes Mukherjee is specially acknowledged. The official website of Nobel Academy has been used for pictures and biographies of Nobel laureates. Web pictures, without copyright protection, were also used in some figures. The remarkable success of the book was due to the active support of the publishers. This is to record our appreciation for the co-operation extended by Shri Jitendar P Vij, and his associates.

We hope that this sixth edition will be friendlier to the students and be more attractive to the teachers. Now this is in your hands to judge.

"End of all knowledge must be building up of character."—Gandhiji

DM Vasudevan
Sreekumari S
Kannan Vaidyanathan
Preface to the First Edition

There are many textbooks of biochemistry written by Western and Indian authors. Then what is the need for yet another textbook? Putting this question to ourselves, we have waited for many years before embarking on this project. Most western textbooks do not emphasise nutrition and such other topics which are very vital to an Indian student. While Indian authors do cover these portions, they sometimes neglect the expanding fields such as molecular biology and immunochemistry. Thus during our experience of more than 25 years in teaching, the students have been seen compelled to depend on different textbooks during their study of biochemistry. We have tried to keep a balance between the basic essentials and the advanced knowledge.

This book is mainly based on the MBBS curriculum. However, some advanced portions have also been given in almost all chapters. These areas will be very beneficial to the readers preparing for their postgraduate entrance examinations.

Chapters on diabetes, cancer and AIDS are included in this book. During their clinical years, the students are going to see such cases quite more often, hence knowledge of applied biochemistry of these diseases will be very helpful. The authors, themselves medical graduates, have tried to emphasise medical applications of the theoretical knowledge in biochemistry in almost all the chapters.

A few questions have been given at the end of most of the chapters. These are not comprehensive to cover all the topics, but have been included only to give emphasis to certain points which may otherwise be left unnoticed by some students.

We are indebted to many persons in compiling this textbook. We are highly obliged to Dr ANP Ummerkutty, Vice-Chancellor, University of Calicut, for his kind gesture of providing an introduction. Dr M Krishnan Nair, Research Director, Veterinary College, Trichur, has provided his unpublished electron micrographs for this book. Dr MV Muraleedharan, Professor of Medicine, and Dr TS Hariharan, Professor of Pharmacology, Medical College, Trichur, have gone through the contents of this book. Their valuable suggestions on the applied aspects of biochemistry have been incorporated. Two of our respected teachers in biochemistry, Prof R Raghunandana Rao and Prof GYN Iyer (both retired) have encouraged this venture. Prof PNK Menon, Dr S Gopinathan Nair, Assistant Professor, Dr Shyam Sundar, Dr PS Vasudevan and Mr K Ramesh Kumar, postgraduate students of this department, have helped in collecting the literature and compiling the materials. Mr. Joby Abraham, student of this college has contributed the sketch for some of the figures. Prof CPK Tharakan, retired professor of English, has taken great pains to go through the entire text and correct the usage of English. The secretarial work has been excellently performed by Mrs Lizy Joseph. Many of our innumerable graduate and postgraduate students have indirectly contributed by compelling us to read more widely and thoroughly.

“A lamp that does not glow itself cannot light another lamp” — Tagore

Our expectation is to bring out new editions every 3 years. Suggestions to improve the contents are welcome from the teachers.

November 1994

Sreekumari S
 SECTION A : CHEMICAL BASIS OF LIFE

1. Biochemical Perspective to Medicine ............................................................................................... 1
   Historical background; Stabilizing forces in Biomolecules; Electrostatic bonds; Hydrophobic interactions;
   van der Waals force; Hydrogen bond; Properties of water; Principles of Thermodynamics; Donnan Membrane
   Equilibrium

2. Subcellular Organelles and Cell Membranes .................................................................................. 7
   Cell Composition, Subcellular organelles, Nucleus, Endoplasmic reticulum, Golgi apparatus, Lysosomes,
   Peroxisomes, Mitochondria. Fluid Mosaic Model, Lipid rafts, Caveolae, Tight junction, Cytoskeleton,
   Transport mechanisms, Facilitated diffusion, Ion channels, Ligand gated channels, Voltage gated channels,
   Ionophores, Active transport, Sodium pump, Uniport, Symport, Antiport, Exocytosis, Endocytosis,
   Pinocytosis, Phagocytosis.

3. Amino Acids: Structure and Properties ........................................................................................ ... 19
   Classification based on structure, Classification based on side chain characters, Classification based on
   metabolic fate, Classification based on nutritional requirement, properties and reactions, Iso-electric point,
   Decarboxylation, Amide formation, Transamination, Oxidative deamination, Amino acid derivatives of
   importance, Peptide bond, Color reactions of amino acids and proteins

4. Proteins: Structure and Function ............................................................................................. ........ 27
   Structure of proteins, primary, secondary, tertiary and quaternary structures, Primary structure of insulin,
   Structure-function relationship, Sequence analysis, iso-electric pH, Precipitation reactions, Denaturation
   of proteins, Heat coagulation, Classification of proteins, Quantitative estimation of proteins.

5. Enzymology: General Concepts and Enzyme Kinetics .................................................................. 40
   Classification, Co-enzymes, Mode of action of enzymes, Active center, Kinetics, Michaelis constant,
   Activation, Competitive inhibition, Noncompetitive inhibition, Allosteric inhibition, Key enzymes, Feedback
   inhibition, Covalent modification, Repression, Induction, Specificity of enzymes, Enzyme engineering,
   Enzyme units, Iso-enzymes.

6. Chemistry of Carbohydrates ................................................................................................... .......... 60
   Monosaccharides, Glucose, Fructose, Mannose, Galactose, Stereoisomers, Epimers, Reactions,
   Benedict’s reaction, Osazone, Glycosides, Amino sugars, Deoxy sugars, Disaccharides, Sucrose, Lactose,
   Maltose, Polysaccharides, Starch, Glycogen, Cellulose, Mucopolysaccharides

7. Chemistry of Lipids ............................................................................................................................ 73
   Classification of lipids, Classification of fatty acids, Saturated fatty acids, Unsaturated fatty acids,
   Polysaturated fatty acids, Triglycerides, Classification of compound lipids, Phospholipids, Liposomes,
   Lechitin, Phospholipases, Lung surfactants, Cephalin, Plasmalogens, Sphingolipids, Nonphosphorylated
   lipids, Compound lipids, Glycerophosphatides, Sphingolipids, Sphingomyelin, Cerebrosides, Gangliosides.

 SECTION B : GENERAL METABOLISM

8. Overview of Metabolism ............................................................................................................... 83
   Experimental approach to study of metabolism, Tissue culture, Radioisotope tracers, Metabolic profile in
   organs, Brain, Skeletal muscle, Cardiac muscle, Adipose tissue, Liver, Metabolic adaptations during
   starvation.
9. Major Metabolic Pathways of Glucose
Digestion and absorption of carbohydrates, Glucose transporters, Regulation of blood sugar, Embden-Meyerhof pathway, Glycolysis, Regulation, Cori’s cycle, BPG shunt, Fate of pyruvate, Gluconeogenesis, Glucose-alanine cycle, Glycogenolysis, Glycogen synthesis, Glycogen storage diseases

10. Minor Metabolic Pathways of Carbohydrates

11. Metabolism of Fatty Acids
Digestion and absorption of fat, Beta oxidation, Energetics, Oxidation of odd chain fatty acids, Alpha oxidation, Omega oxidation, Organic acidurias, De novo synthesis of fatty acids, Elongation, Synthesis of triglycerides, Metabolism of adipose tissue, Hormone sensitive lipase, Liver adipose tissue axis, Obesity, Fatty liver, Lipotropic factors, Ketone bodies, Ketogenesis, Ketolysis, Ketosis.

12. Cholesterol and Lipoproteins
Steroids, Structure of cholesterol, Biosynthesis of cholesterol, Plasma lipids, Transport of lipids, Lipoproteins, Apolipoproteins, Chylomicrons, VLDL, LDL, HDL, Lp(a), Free fatty acid, Non-esterified fatty acids, Bile salts, Steroid hormones.

13. MCFA, PUFA, Prostaglandins and Compound Lipids
Digestion of medium chain fatty acids, Monounsaturated fatty acids, Beta oxidation of unsaturated fatty acids, Polyunsaturated fatty acids, Desaturation of fatty acids, Essential fatty acids, Eicosanoids, Prostaglandins, Leukotrienes, Very long chain fatty acids, Synthesis of Compound Lipids, Phosphatidyl choline, Sphingomyelin, Lipid storage diseases.

14. General Amino Acid Metabolism (Urea Cycle, One Carbon Metabolism)
Digestion of proteins, Absorption of amino acids, Meister cycle, Intracellular protein degradation, Cathepsins, Ubiquitin pathway, Proteasomes, Inter-organ transport of amino acids, Glucose Alanine cycle; Catabolism of amino acids, Formation of ammonia, Transamination, Oxidative deamination, Nonoxidative deamination, Disposal of ammonia, Urea cycle, Disorders of urea cycle, Hepatic coma, Blood urea. One carbon compounds, Generation and utilization of one carbon groups.

15. Simple, Hydroxy and Sulfur Containing Amino Acids (Glycine, Serine, Methionine, Cysteine)
Glycine, Creatine, Creatinine, Primary hyperoxaluria, Serine, Serine choline glycine cycle, Selenocysteine, Alanine, Glucose alanine cycle, Beta alanine, Threonine, Methionine, Transmethylation reactions, Cysteine, Glutathione, Sulphur, Cystinuria, Homocystinurias, Cystathioninuria.

16. Acidic, Basic and Branched Chain Amino Acids (Glutamic Acids, Aspartic Acid, Lysine, Arginine, Nitric Oxide, Histidine, Valine, Leucine, Isoleucine)
Glutamic acid, GABA, Glutamine, Aspartic acid, Asparagine, dicarboxylic amino aciduria, Lysine, Arginine, Nitric Oxide, Ornithine, Polyamine synthesis, Valine, Leucine, Isoleucine, Maple syrup urine disease, Isovaleric aciduria, Histidine, Histamine.

17. Aromatic Amino Acids and Amino Acidurias (Phenylalanine, Tyrosine, Tryptophan, Proline)
Phenylalanine, Tyrosine, Melanin, Catecholamines, Phenylketonuria, Alcaptonuria, Albinism, Tryptophan, Nicotinic acid pathway, Serotonin, Melatonin, Indican, Hartnup’s disease, Proline, Inter-relation of amino acids; Amino acidurias.

18. Citric Acid Cycle
Citric acid cycle reactions, Significance of TCA cycle, Amphibolic role, Regulation, Integration of metabolism,
19. Biological Oxidation and Electron Transport Chain ................................................................. 223
Primary, secondary and tertiary metabolism, Redox potential, Biological oxidation, Oxidases, Cytochrome oxidase, Dehydrogenases, NAD+, FAD, Cytochromes, Oxygenases, High energy compounds, Organization of electron transport chain, NADH shuttle, Malate aspartate shuttle, Flow of electrons, Oxidative phosphorylation, Chemi-osmotic theory, ATP synthase, Inhibitors of ATP synthesis, Uncouplers of oxidative phosphorylation, Ionophores.

20. Free Radicals and Anti-Oxidants ................................................................................................. 236
Free radicals, Reactive oxygen species, Generation, Damage, Free radical scavenger systems, Inflammation, Respiratory diseases, Retrolental fibroplasia, Reperfusion injury, Atherosclerosis, Skin diseases, Age-related diseases, Lipid peroxidation, Initiation, propagation and termination phases, Preventive anti-oxidants, Chain breaking anti-oxidants.

21. Heme Synthesis and Breakdown .............................................................................................. 242
Structure of heme, Biosynthesis of heme, Porphyria, Shunt bilirubin, Catabolism of heme, Plasma bilirubin, Hyperbilirubinemias, Congenital hyperbilirubinemia, Hemolytic jaundice, Hepatocellular jaundice, Obstructive jaundice, Differential diagnosis of jaundice.

22. Hemoglobin (Structure, Oxygen and Carbon Dioxide, Transport, Abnormal Hemoglobins) .... 254
Structure of hemoglobin, Transport of gases, Oxygen dissociation curve, Hemoglobin interaction, Effect of 2,3-BPG, Isohydric transport of carbon dioxide, Chloride shift, Fetal hemoglobin (HbF), Hemoglobin derivatives, Carboxy hemoglobin, Met-hemoglobin, Hemoglobin variants, Sickle cell hemoglobin (HbS), Thalassemias, Myoglobin, Anemias.

SECTION C : CLINICAL AND APPLIED BIOCHEMISTRY

23. Clinical Enzymology and Biomarkers ..................................................................................... 266
Creatine kinase, Cardiac troponins, Lactate dehydrogenase, Markers of Cardiac diseases; Aspartate amino transferase, Alanine amino transferase, Alkaline phosphatase, Nucleotide phosphatase, Gamma glutamyl transferase, Markers of liver diseases, Acid phosphatase, Cholinesterase, Glucose-6-phosphate dehydrogenase, Amylase, Lipase, Aldolase, Enolase, Enzymes as therapeutic agents, Enzymes used for diagnosis, Immobilized enzymes.

24. Regulation of Blood Glucose, Insulin and Diabetes Mellitus .................................................. 274
Regulation of blood glucose, Determination of glucose, Glucose tolerance test, Impaired glucose tolerance, Impaired fasting glycemia, Gestational diabetes mellitus, Alimentary glucosuria, Renal glucosuria, Reducing substances in urine, Glycosuria, Diabetes mellitus, Clinical presentation, Diabetic keto acidosis, Hyperosmolar nonketotic coma, Lactic acidosis, Chronic complications, Glycated hemoglobin.

25. Cardiovascular Diseases and Hyperlipidemias ........................................................................ 292

26. Liver and Gastric Function Tests ............................................................................................... 301
Tests for liver function, Serum bilirubin, Classification of jaundice, Bile acids and bile salts, Tests based on the metabolic capacity of the liver, Test based on synthetic function, Serum enzymes as markers of hepatobiliary diseases, Gastric function, Hydrochloric acid secretion, Assessment of free and total acidity, Pancreatic function tests.

27. Kidney Function Tests ............................................................................................................. 314
Formation of urine, Functions of the tubules, Renal threshold, Tubular maximum, Abnormal constituents of urine, Proteinuria, Reducing sugars, Clearance tests, Inulin clearance, Creatinine clearance test, Cystatin C, Urea clearance test, Tests for tubular function, Osmolality, Acidification test.
28. Plasma Proteins

29. Acid-Base Balance and pH

30. Electrolyte and Water Balance
Body water compartments, Donnan membrane equilibrium, Osmolality, Electrolyte concentration of body fluid compartments, Regulation of sodium and water balance, Renin-angiotensin system, Assessment, Disturbances, Isotonic contraction, Hypotonic contraction, Hypertonic contraction, Isotonic expansion, Hypotonic expansion, Hypertonic expansion; Clinical applications of Sodium, Potassium, Chloride, Hypernatremia, Hyponatremia, Hypokalemia, Hyperkalemia, Hyperchloremia, Hypochloremia.

31. Body Fluids (Milk, CSF, Amniotic Fluid)
Milk, Colostrum, Aqueous humor, Cerebrospinal fluid, Amniotic fluid, Assessment of fetal maturity.

32. Clinical Laboratory: Screening of Metabolic Diseases; Quality Control
Prenatal diagnosis; AFP, hCG, uE3, DIA, PAPP-A; Newborn screening; Investigations for Metabolic disorders; Reference values, Pre-analytical variables, Collection of blood, Anticoagulants, Preservatives for blood, Urine collection, Quality control, Accuracy, Precision, Specificity, Sensitivity, Limits of errors allowable in the laboratory, Percentage error.

SECTION D : NUTRITION

33. Fat Soluble Vitamins (A, D, E, K)
Vitamin A, Role in vision, Wald’s visual cycle, Vitamin D, Calcitriol, Vitamin E, Vitamin K.

34. Water Soluble Vitamins (Thiamine, Riboflavin, Niacin, Pyridoxine, Pantothenic acid, Biotin, Folic acid, Vitamin B_{12} and Ascorbic acid)
Thiamine (B_{1}), Beriberi, Riboflavin (B_{2}), Niacin, Pyridoxine (B_{6}), Pantothenic acid, Acetyl CoA, Succinyl CoA, Biotin, Folic acid, Folate antagonists, Folate trap, Vitamin B_{12}, Choline, Inositol, Ascorbic acid (Vitamin C), Scurvy.

35. Mineral Metabolism and Abnormalities
Calcium, Homeostasis, Parathyroid hormone, Calcitonin, Hypercalcemia, Hypocalcemia, Bone metabolism; Markers of bone metabolism; Phosphorus, Magnesium, Sulphur, Iron, Absorption, Iron deficiency, Hemochromatosis, Copper, Ceruloplasmin, Iodine, Zinc, Fluoride, Selenium, Manganese, Cobalt, Nickel, Chromium, Lithium.

36. Energy Metabolism and Nutrition
Calorific value, Respiratory quotient, Resting metabolic rate (RMR), Specific dynamic action, Requirements, Dietary carbohydrates, Dietary fiber, Nutritional importance of lipids, Nutritional importance of proteins, Essential amino acids, Nitrogen balance, Biological value of proteins, Protein energy malnutrition (PEM), Marasmus, Kwashiorkor, Obesity, Prescription of diet, Special diets, Glycemic index, Total parenteral nutrition.

37. Detoxification and Biotransformation of Xenobiotics
Phase one reactions, Oxidative reactions, Reductive reactions, Hydrolysis, Phase two reactions, Conjugation, Phase three reactions.
38. Environmental Pollution and Heavy Metal Poisons
Corrosives and irritants, Organic irritant poisons, Neurotoxins, Heavy metal poisons, Lead, Mercury, Aluminium, Arsenic, Pesticides and insecticides, Organophosphorus compounds, Industrial hazards, Air pollutants, Sulphur dioxide, Toxic substances in foodstuffs, Lathyrisim.

SECTION E: MOLECULAR BIOLOGY

39. Nucleotides; Chemistry and Metabolism

40. Deoxyribo Nucleic Acid (DNA): Structure and Replication

41. Transcription and Translation
Ribonucleic acid, mRNA, RNA polymerase, Transcription, Transcription signals, Initiation of transcription, Elongation of transcription, Termination of transcription, Post-transcriptional processing, Spliceosomes, Ribozymes, Introns and exons, Reverse transcriptase, tRNA, rRNA, Ribosomes, snRNA, Protein biosynthesis, Genetic code, Translation, Initiation of translation, Elongation of translation, Termination of translation, Protein targeting, Post-translational processing, Protein folding, Chaperones, Heat shock proteins, Inhibitors of protein synthesis, Antibiotics, Mitochondrial DNA and RNA, Oxphos diseases; Genomics and proteomics; Micro RNA, interfering RNA, RNA silencing; Antisense therapy; Fusion proteins.

42. Inheritance, Mutations and Control of Gene Expression
Principles of heredity, Dominant inheritance, Recessive inheritance, X-linked inheritance, Population genetics, Chromosomal recombination, Genetic loci on chromosomes, Mutations, Point mutation, Termination codon mutation, Frame shift mutation, Conditional mutation, Ame’s test, Mutagens, Site directed mutagenesis, Cell cycle, Check points, Oncosuppressor proteins, Rb protein, p53, Apoptosis, Caspase activation cascade, Regulation of gene expression, Operon concept, Repression, Derepression, Lac operon, Hormone response elements; Gene amplifications, Gene switching, Viruses, Antiviral agents; Lysogeny; Transduction; Epigenetic modifications.

43. Recombinant DNA Technology and Gene Therapy
Application of recombinant DNA technology, Restriction endonucleases, Restriction map, cDNA, Vectors, Plasmids, Cosmids, Homopolymer tailing, Chimeric molecules, Cloning, Transfection, Selection, Expression vectors, Gene therapy, Vectors for gene therapy, Retroviruses, Adenoviruses, Plasmid liposome complex; Stem cells.

SECTION F: HORMONES

44. Mechanisms of Action of Hormones
G proteins, Cyclic AMP, Protein kinases, Phosphatidyl inositol biphosphate, Inositol triphosphate, Diacyl glycerol, Cyclic GMP, Steroid receptors, Insulin Signaling pathway, mTOR, Jak-STAT pathway, NFkB

45. Hypothalamic and Pituitary Hormones
Anti-diuretic hormone, Oxytocin, Hypothalamic releasing factors, Growth hormone, Adrenocorticotropic hormone, Endorphins, Glycoprotein hormones, Thyroid stimulating hormone, Gonadotropins.
46. Steroid Hormones ............................................................................................................ 532
   Adrenal cortical hormones, Synthesis of steroid hormones, 17-ketosteroids, Assessment of glucocorticoid secretion, Assessment of mineralocorticoid function, Adrenal hyperfunction, Adrenal hypofunction, Primary hyperaldosteronism, Adrenogenital syndrome, Ovarian hormones, Testicular hormones.

47. Thyroid Hormones ........................................................................................................................... 538
   Thyroid hormones, Synthesis, Secretion, Mechanism of action, Metabolic effects, Assessment of thyroid function, Hyperthyroidism, Hypothyroidism.

48. Signal Molecules and Growth Factors ......................................................................................... 543
   Adiponectin, Cadherins, CKK, C-Jun, C-Kit, EGFR, Erythropoietin, ERK, FGF, GIP, Gastrin, Gaunylin, Ghrelin, GLP, GSK, GCSF, GMCSF, HSP, HGF, HGFR, HER2/neu, HIF, ICAM, IGF, IGFR, IR, IRS, Interferons, JNKs, MCSF, MIP, MMP, MAPKK, MCP, Neuropeptide Y, Osteocalcin, Osteonectin, Osteopontin, Osteoprotogerin, p38, p53, p70S6, Pancreatic polypeptide, PIGF, PDGF, PARP, Protein C, RANTES, Rb, Resistin, SSA, SSAP, Secretin, Selectins, Somatostatin, STAT, Tau, TGF, Thrombopoietin, Thrombomodulin, TIMP, TNF, VCAM, VEGF, VIP

SECTION G : ADVANCED BIOCHEMISTRY

49. Immunochemistry ........................................................................................................................... 553

50. Biochemistry of AIDS and HIV ................................................................................................ ........ 563
   Transmission, Natural course of the disease, Laboratory analysis, Virus, Replication, HIV genes and gene products, Immunology of AIDS, Anti-HIV drugs, Prevention.

51. Biochemistry of Cancer ...................................................................................................... ............. 567
   Etiology, Chemical carcinogens, Antimutagens, Oncogenic viruses, Oncogenes, Proto oncogene, Antioncogenes, Oncosuppressor genes, Growth factors, Tumour kinetics, Doubling time, Contact inhibition, Anchorage dependence, Apoptosis, Oncofetal antigens, Tumor markers, Alpha fetoprotein, Carcinoeobryonic antigen, Tissue polypeptide antigen, Prostate specific antigen, Other tumor markers, Anticancer drugs, Drug resistance.

52. Tissue Proteins in Health and Disease ....................................................................................... ... 581

53. Applications of Isotopes in Medicine ........................................................................................ ..... 592
   Subatomic particles, Valency, Isotopes, Radioactive decay, Alpha, Beta, Gamma radiations, Half-life, Units of radioactivity, Research applications, Diagnostic applications, Teletherapy, Radiosensitivity, Fractionation of doses, Biological effects of radiation, Radiation protection.

54. General Techniques for Separation, Purification and Quantitation ........................................... 599
   Electrophoresis, PAGE, Immuno-electrophoresis, High voltage electrophoresis, Capillary electrophoresis, Chromatography (adsorption, partition, ion exchange, gel filtration, affinity), HPLC, Ultracentrifugation, Determination of molecular weight of proteins, Radiimmunoassay, ELISA test, pH meter, Colourimeter, Spectrophotometer, Flame photometer, Autoanalysers, Dry chemistry systems, Ion selective electrodes, Tandem mass spectroscopy, Fluorescent activated cell sorter.
55. Molecular Diagnostics

Gene library, Linkage analysis, Microsatellite markers, Human Genome Project, Southern blot, In-situ hybridisation, Northern blotting, Western blot, Animal cloning, Molecular cloning in clinical diagnosis and management, DNA finger printing, Restriction fragment length polymorphism (RFLP), Polymerase chain reaction (PCR), Reverse PCR, Hybridoma technology and Monoclonal antibodies, Single Strand Conformation Polymorphism (SSCP), Heteroduplex Analysis, Conformation Sensitive Gel Electrophoresis (CSGE), Protein Truncation Test (PTT), Denaturing High Performance Liquid Chromatography (DHPLC), Transgenesis, DNA sequencing, Bio-informatics, Nanotechnology.

APPENDICES
I. Abbreviations Used in this book ................................................................. 625
II. Normal values (Reference values) ................................................................. 629
III. Conversion Chart ....................................................................................... 631
IV. Greek Alphabet (Commonly Used letters as Symbols) ................................. 631
V. Recommended Daily Allowance (RDA) of Essential Nutrients .................... 632
VI. Composition of Nutrients in Selected Common Food Materials ................ 633
VII. Table Showing Surface Area for Different Heights and Weights ............... 635
VIII. Ideal Body Weight and Height of Different Age Groups ............................ 635

Index .............................................................................................................. 637
The word chemistry is derived from the Greek word "chemi" (the black land), the ancient name of Egypt. Indian medical science, even from ancient times, had identified the metabolic and genetic basis of diseases. Charaka, the great master of Indian Medicine, in his treatise (circa 400 BC) observed that madhumeha (diabetes mellitus) is produced by the alterations in the metabolism of carbohydrates and fats; the statement still holds good.

Biochemistry has developed as an offshoot of organic chemistry, and this branch was often referred as "physiological chemistry". The term "Biochemistry" was coined by Neuberg in 1903 from Greek words, bios (= life) and chymos (= juice). One of the earliest treatises in biochemistry was the "Book of Organic Chemistry and Its Applications to Physiology and Pathology", published in 1842 by Justus von Liebig (1803-73), who introduced the concept of metabolism. The "Textbook of Physiological Chemistry" was published in 1877 by Felix Hoppe-Seyler (1825-95), who was professor of physiological chemistry at Strausbourge University, France. Some of the milestones in the development of science of biochemistry are given in Table 1.1.

Biochemistry is perhaps the most rapidly developing subject in medicine. No wonder, the major share of Nobel prizes in medicine has gone to research workers engaged in biochemistry. Thanks to the advent of DNA-recombination technology, genes can now be transferred from one person to another, so that many of the genetically determined diseases are now amenable to gene therapy. Many genes, (e.g. human insulin gene) have already been transferred to microorganisms for large scale production of human proteins. Advances in genomics like RNA interference for silencing of genes and creation of transgenic animals by gene targeting of embryonic stem cells are opening up new vistas in therapy of diseases like cancer and AIDS. It is hoped that in future, physician will be able to treat the patient, understanding his genetic basis, so that very efficient "designer medicine" could cure the diseases. The large amount of data, especially with regard to single
Textbook of Biochemistry; Section A: Chemical Basis of Life

nucleotide polymorphisms (SNPs) that are available, could be harnessed by "Bioinformatics". Computers are already helping in drug designing process. Studies on oncogenes have identified molecular mechanisms of control of normal and abnormal cells. Medical practice is now taking more and more help from the field of biochemistry. With the help of human genome project (HGP) the sequences of the whole human genes are now available; it has already made great impact on medicine and related health sciences.

BIOMOLECULES
More than 99% of the human body is composed of 6 elements, i.e. oxygen, carbon, hydrogen, nitrogen, calcium and phosphorus. Human body is composed of about 60% water, 15% proteins, 15% lipids, 2% carbohydrates and 8% minerals. Molecular structures in organisms are built from 30 small precursors, sometimes called the alphabet of biochemistry. These are 20 amino acids, 2 purines, 3 pyrimidines, sugars (glucose and ribose), palmitate, glycerol and choline.

In living organisms the biomolecules are ordered into a hierarchy of increasing molecular complexity. These biomolecules are covalently linked to each other to form macromolecules of the cell, e.g. glucose to glycogen, amino acids to proteins, etc. Major complex biomolecules are Proteins, Polysaccharides, Lipids and Nucleic acids. The macromolecules associate with each other by noncovalent forces to form supramolecular systems, e.g. ribosomes, lipoproteins.

Finally, at the highest level of organisation in the hierarchy of cell structure, various supramolecular complexes are further assembled into cell organelle. In prokaryotes (e.g. bacteria; Greek word "pro" = before; karyon = nucleus), these macromolecules are seen in a homogeneous matrix; but in eukaryotic cells (e.g. higher organisms; Greek word "eu" = true), the cytoplasm contains various subcellular organelles. Comparison of prokaryotes and eukaryotes are shown in Table 1.2.

STUDY OF METABOLIC PROCESSES
Our food contains carbohydrates, fats and proteins as principal ingredients. These macromolecules are

to be first broken down to small units; carbohydrates to monosaccharides and proteins to amino acids. This process is taking place in the gastrointestinal tract and is called digestion or primary metabolism. After absorption, the small molecules are further broken down and oxidised to carbon dioxide. In this process, NADH or FADH₂ are generated. This is named as secondary or intermediary metabolism. Finally, these reducing equivalents enter the electron transport chain in the mitochondria, where they are oxidised to water; in this process energy is trapped as ATP. This is termed tertiary metabolism. Metabolism is the sum of all chemical changes of a compound inside the body, which includes synthesis (anabolism) and breakdown (catabolism). (Greek word, kata = down; ballein = change).

STABILIZING FORCES IN MOLECULES

1. Covalent Bonds
Molecules are formed by sharing of electrons between atoms (Fig. 1.1).

2. Ionic Bonds or Electrostatic Bonds
Ionic bonds result from the electrostatic attraction between two ionized groups of opposite charges (Fig. 1.2). They are formed by transfer of one or more electrons from the outermost orbit of an electropositive atom to the outermost orbit of an electronegative atom. This transfer results in the formation of a 'cation' and an 'anion', which get consequently bound by an ionic bond. Common examples of such compounds include NaCl, KBr and NaF.

With regard to protein chemistry, positive charges are produced by epsilon amino group of lysine, guanidinium group of arginine and imidazolium group of histidine. Negative charges are provided by beta and gamma carboxyl groups of aspartic acid and glutamic acid (Fig. 1.3).

3. Hydrogen Bonds
These are formed by sharing of a hydrogen between two electron donors. Hydrogen bonds result from electrostatic attraction between an electro-negative electron donor and an electron acceptor. Normally, a hydrogen atom forms a covalent bond with only one other atom. However, a hydrogen atom can covalently bond to a donor atom, may form an additional weak association, the hydrogen bond with an acceptor atom. In biological systems, both donors and acceptors are usually nitrogen or oxygen atoms, especially those atoms in amino (NH₂) and hydroxyl (OH) groups.

With regard to protein chemistry, hydrogen releasing groups are -NH (imidazole, indole, peptide); -OH (serine, threonine) and -NH₂ (arginine, lysine). Hydrogen accepting groups are COO⁻ (aspartic, glutamic) C=O (peptide); and S–S (disulphide). The DNA structure is maintained by hydrogen bonding between the purine and pyrimidine residues.
4. **Hydrophobic Interactions**

Non-polar groups have a tendency to associate with each other in an aqueous environment; this is referred to as hydrophobic interaction. These are formed by interactions between nonpolar hydrophobic side chains by eliminating water molecules. The force that causes hydrophobic molecules or nonpolar portions of molecules to aggregate together rather than to dissolve in water is called the 'hydrophobic bond' (Fig. 1.4). This serves to hold lipophilic side chains of amino acids together. Thus, nonpolar molecules will have minimum exposure to water molecules.

5. **Van Der Waals Forces**

These are very weak forces of attraction between all atoms, due to oscillating dipoles, described by the Dutch physicist Johannes van der Waals (1837-1923). He was awarded Nobel prize in 1910. These are short range attractive forces between chemical groups in contact. Van der Waals interactions occur in all types of molecules, both polar and nonpolar. The energy of the van der Waals interaction is about 1 kcal/mol and are unaffected by changes in pH. This force will drastically reduce, when the distance between atoms is increased. Although very weak, van der Waals forces collectively contribute maximum towards the stability of protein structure, especially in preserving the nonpolar interior structure of proteins.

**WATER: THE UNIVERSAL SOLVENT**

Water constitutes about 70 to 80 percent of the weight of most cells. The hydrogen atom in one water molecule is attracted to a pair of electrons in the outer shell of an oxygen atom in an adjacent molecule. The structure of liquid water contains hydrogen-bonded networks (Fig. 1.5).

The crystal structure of ice depicts a tetrahedral arrangement of water molecules. Four others bound by hydrogen bonds surround each oxygen atom. On melting, the molecules get much closer and this results in the increase in density of water. Hence, liquid water is denser than solid ice. This also explains why ice floats on water.

Water molecules are in rapid motion, constantly making and breaking hydrogen bonds with adjacent molecules. As the temperature of water increases toward 100°C, the kinetic energy of its molecules becomes greater than the energy of the hydrogen bonds connecting them, and the gaseous form of water appears. A few gifted properties of water make it the most preferred medium for all cellular reactions and interactions.

a. Water is a polar molecule. Molecules with polar bonds that can easily form hydrogen bonds with water can dissolve in water and are termed "hydrophilic".

b. It has immense hydrogen bonding capacity both with other molecules and also the adjacent water molecules. This contributes to cohesiveness of water.

c. Water favors hydrophobic interactions and provides a basis for metabolism of insoluble substances. Water expands when it is cooled from 4°C to 0°C, while normally liquids are expected to contract due to cooling. As water is heated from 0°C to 4°C, the hydrogen bonds begin to break. This results in a decrease in volume or in other words, increase in density. Hence, water attains high density at 4°C. However, above 4°C the effect of temperature predominates.

**PRINCIPLES OF THERMODYNAMICS**

Thermodynamics is concerned with the flow of heat and it deals with the relationship between heat and work. Bioenergetics, or biochemical thermodynamics, is the study of the energy changes accompanying biochemical reactions. Biological systems use chemical energy to power living processes.

1. **First Law of Thermodynamics**

The total energy of a system, including its surroundings, remains constant.
Or, \( \Delta E = Q - W \), where \( Q \) is the heat absorbed by the system and \( W \) is the work done. This is also called the **law of conservation of energy**. If heat is transformed into work, there is proportionality between the work obtained and the heat dissipated. A system is an object or a quantity of matter, chosen for observation. All other parts of the universe, outside the boundary of the system, are called the surroundings.

### 2. Second Law of Thermodynamics

The total entropy of a system must increase if a process is to occur spontaneously. A reaction occurs spontaneously if \( \Delta E \) is negative, or if the entropy of the system increases. **Entropy** (\( S \)) is a measure of the degree of randomness or disorder of a system. Entropy becomes maximum in a system as it approaches true equilibrium. **Enthalpy** is the heat content of a system and **entropy** is that fraction of enthalpy which is not available to do useful work.

A closed system approaches a state of equilibrium. Any system can spontaneously proceed from a state of low probability (ordered state) to a state of high probability (disordered state). The entropy of a system may decrease with an increase in that of the surroundings. The second law may be expressed in simple terms as \( Q = T \times \Delta S \), where \( Q \) is the heat absorbed, \( T \) is the absolute temperature and \( \Delta S \) is the change in entropy.

### 3. Gibb's Free Energy Concept

The term free energy is used to get an equation combining the first and second laws of thermodynamics. Thus, \( \Delta G = \Delta H - T \Delta S \), where \( \Delta G \) is the change in free energy, \( \Delta H \) is the change in enthalpy or heat content of the system and \( \Delta S \) is the change in entropy. **The term free energy denotes a portion of the total energy change in a system that is available for doing work.**

For most biochemical reactions, it is seen that \( \Delta H \) is nearly equal to \( \Delta E \). So, \( \Delta G = \Delta E - T \Delta S \). Hence, \( \Delta G \) or free energy of a system depends on the change in internal energy and change in entropy of a system.

### 4. Standard Free Energy Change

It is the free energy change under standard conditions. It is designated as \( \Delta G^0 \). The standard conditions are defined for biochemical reactions at a pH of 7 and 1 M concentration, and differentiated by a priming sign \( \Delta G^0 \). It is directly related to the equilibrium constant. Actual free energy changes depend on reactant and product.

Most of the reversible metabolic reactions are near equilibrium reactions and therefore their \( \Delta G \) is nearly zero. The net rate of near equilibrium reactions are effectively regulated by the relative concentration of substrates and products. The metabolic reactions that function far from equilibrium are irreversible. The velocity of these reactions are altered by changes in enzyme activity. A highly exergonic reaction is irreversible and goes to completion. Such a reaction that is part of a metabolic pathway, confers direction to the pathway and makes the entire pathway irreversible.

### Three Types of Reactions

**A.** A reaction can occur spontaneously when \( \Delta G \) is negative. Then the reaction is **exergonic**. If \( \Delta G \) is of great magnitude, the reaction goes to completion and is essentially irreversible.

**B.** When \( \Delta G \) is zero, the system is at **equilibrium**.

**C.** For reactions where the \( \Delta G \) is positive, an input of energy is required to drive the reaction. The reaction is termed as **endergonic** and those with a negative \( \Delta G \) as exergonic. (Examples given below). Similarly a reaction may be **exothermic** (\( \Delta H \) is negative), **isothermic** (\( \Delta H \) is zero) or **endothermic** (\( \Delta H \) is positive).

Energetically unfavorable reaction may be driven forward by coupling it with a favorable reaction.

Glucose + Pi → Glucose-6-phosphate (reaction1)

ATP + H₂O → ADP + Pi (reaction 2)

Glucose+ATP→Glucose-6-phosphate+ADP (3)

Reaction 1 cannot proceed spontaneously. But the 2nd reaction is coupled in the body, so that the reaction becomes possible. For the first reaction, \( \Delta G^0 \) is +13.8 kJ/mole; for the second reaction, \( \Delta G^0 \) is −30.5 kJ/mole. When the two reactions are coupled in the reaction 3, the \( \Delta G^0 \) becomes −16.7 kJ/mole, and hence the reaction becomes possible. Details on ATP and other high-energy phosphate bonds are described in Chapter 19.

Reactions of catabolic pathways (degradation or oxidation of fuel molecules) are usually exergonic,
whereas anabolic pathways (synthetic reactions or building up of compounds) are endergonic. Metabolism constitutes anabolic and catabolic processes that are well co-ordinated.

DONNAN MEMBRANE EQUILIBRIUM

When two solutions are separated by a membrane permeable to both water and small ions, but when one of the compartments contains impermeable ions like proteins, distribution of permeable ions occurs according to the calculations of Donnan.

In Fig. 1.6, the left compartment contains NaR, which will dissociate into Na⁺ and R⁻. Then Na⁺ can diffuse freely, but R⁻ having high molecular weight cannot diffuse. The right compartment contains NaCl, which dissociates into Na⁺ and Cl⁻. Both ions can diffuse freely.

Thus, if a salt of NaR is placed in one side of a membrane, at equilibrium

\[ \text{Na}^+ \times \text{R}^- \times \text{H}^+ \times \text{OH}^- = \text{Na}^+ \times \text{OH}^- \times \text{H}^+ \]

To convey the meaning of the mathematical values, a hypothetical quantity of each of the ion is also incorporated in brackets. Initially 5 molecules of NaR are added to the left compartment and 10 molecules of NaCl in the right compartment and both of them are ionized (Fig. 1.6A). When equilibrium is reached, the distributions of ions are shown in Figure 1.6B. According to Donnan’s equilibrium, the products of diffusible electrolytes in both the compartments will be equal, so that

\[ [\text{Na}^+] \times [\text{Cl}^-] \times \text{L} = [\text{Na}^+] \times [\text{Cl}^-] \times \text{R} \]

If we substitute the actual numbers of ions, the formula becomes

9 x 4 in left = 6 x 6 in right

Donnan’s equation also states that the electrical neutrality in each compartment should be maintained. In other words the number of cations should be equal to the number of anions, such that

In left : Na⁺ = R⁻ + Cl⁻; substituting: 9 = 5 + 4

In right : Na⁺ = Cl⁻; substituting: 6 = 6

The equation should also satisfy that the number of sodium ions before and after the equilibrium are the same; in our example, initial Na⁺ in the two compartments together is 5 + 10 = 15; after equilibrium also, the value is 9 + 6 = 15. In the case of chloride ions, initial value is 10 and final value is also 4 + 6 = 10.

In summary, Donnan’s equations satisfy the following results:
1. The products of diffusible electrolytes in both compartments are equal.
2. The electrical neutrality of each compartment is maintained.
3. The total number of a particular type of ions before and after the equilibrium is the same.
4. As a result, when there is non-diffusible anion on one side of a membrane, the diffusible cations are more, and diffusible anions are less, on that side.

Clinical Applications of the Equation
1. The total concentration of solutes in plasma will be more than that of a solution of same ionic strength containing only diffusible ions; this provides the net osmotic gradient (see under Albumin, in Chapter 28).
2. The lower pH values within tissue cells than in the surrounding fluids are partly due to the concentrations of negative protein ions within the cells being higher than in surrounding fluids.
3. The pH within red cells is lower than that of the surrounding plasma is due, in part, to the very high concentration of negative non-diffusible hemoglobin ions. This will cause unequal distribution of H⁺ ions with a higher concentration within the cell.
4. The chloride shift in erythrocytes as well as higher concentration of chloride in CSF are also due to Donnan’s effect (Chapter 22).
CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Nucleus
2. Endoplasmic reticulum
3. Golgi apparatus
4. Lysosomes
5. Mitochondria
6. Plasma membrane
7. Transport mechanisms
8. Simple and facilitated diffusion
9. Ion channels
10. Active transport
11. Uniport, symport and antiport

SUBCELLULAR ORGANELLES
Cells contain various organized structures, collectively called as cell organelles (Fig. 2.1). When the cell membrane is disrupted, either by mechanical means or by lysing the membrane by Tween-20 (a lipid solvent), the organized particles inside the cell are homogenised. This is usually carried out in 0.25 M sucrose at pH 7.4. The organelles could then be separated by applying differential centrifugal forces (Table 2.1). Albert Claude got Nobel prize in 1974 for fractionating subcellular organelles.

Marker Enzymes
Some enzymes are present in certain organelles only; such specific enzymes are called as marker enzymes (Table 2.1). After centrifugation, the separated organelles are identified by detection of marker enzymes in the sample.

NUCLEUS
1. It is the most prominent organelle of the cell. All cells in the body contain nucleus, except mature RBCs in circulation. The uppermost layer of skin also may not possess a readily identifiable nucleus. In some cells, nucleus occupies most of the available space, e.g. small lymphocytes and spermatozoa.
2. Nucleus is surrounded by two membranes: the inner one is called perinuclear membrane with

![Fig. 2.1. Typical cell](image1)

![Fig. 2.2. Nucleus](image2)
numerous pores (Fig. 2.2). The outer membrane is continuous with membrane of endoplasmic reticulum.

3. Nucleus contains the DNA, the chemical basis of genes which governs all the functions of the cell. The very long DNA molecules are complexed with proteins to form chromatin and are further organized into chromosomes.

4. DNA replication and RNA synthesis (transcription) are taking place inside the nucleus.

5. In some cells, a portion of the nucleus may be seen as lighter shaded area; this is called nucleolus (Fig. 2.2). This is the area for RNA processing and ribosome synthesis. The nucleolus is very prominent in cells actively synthesizing proteins. Gabriel Valentine in 1836 described the nucleolus.

ENDOPLASMIC RETICULUM (ER)

1. It is a network of interconnecting membranes enclosing channels or cisternae, that are continuous from outer nuclear envelope to outer plasma membrane. Under electron microscope, the reticular arrangements will have railway track appearance (Fig. 2.1). George Palade was awarded Nobel prize in 1974, who identified the ER.

2. This will be very prominent in cells actively synthesizing proteins, e.g. immunoglobulin secreting plasma cells. The proteins, glycoproteins and lipoproteins are synthesized in the ER.

3. Detoxification of various drugs is an important function of ER. **Microsomal cytochrome P-450** hydroxylates drugs such as benzyprine, aminopyrine, aniline, morphine, phenobarbitone, etc.

4. According to the electron microscopic appearance, the ER is generally classified into rough and smooth varieties. The rough appearance is due to ribosomes attached to cytoplasmic side of membrane where the proteins are being synthesized.

5. When cells are fractionated, the complex ER is disrupted in many places. They are automatically re-assembled to form microsomes.

GOLGI APPARATUS

1. Camillo Golgi described the structure in 1898 (Nobel prize 1906). The Golgi organelle is a network of flattened smooth membranes and vesicles. It may be considered as the converging area of endoplasmic reticulum (Fig. 2.1).

2. While moving through ER, carbohydrate groups are successively added to the nascent proteins. These glycoproteins reach the Golgi area.

3. Golgi apparatus is composed of cis, medial and trans cisternae. Glycoproteins are generally transported from ER to cis Golgi (proximal cisterna), then to medial Golgi (intermediate cisterna) and finally to trans Golgi (distal cisterna) for temporary storage. Trans Golgi are particularly abundant with vesicles containing glycoproteins. Newly synthesized proteins are sorted first according to the sorting signals available in the proteins. Then they are packed into transport vesicles having different types of coat proteins. Finally, they are transported into various destinations; this is an energy dependent process.

4. Main function of Golgi apparatus is protein sorting, packaging and secretion.

5. The finished products may have any one of the following destinations:
   a. They may pass through plasma membrane to the surrounding medium. This forms continuous secretion, e.g. secretion of immunoglobulins by plasma cells.
   b. They reach plasma membrane and form an integral part of it, but not secreted.
   c. They are formed into a secretory vesicle, where these products are stored for a longer time. Under appropriate stimuli, the contents are secreted. Release of trypsinogen by pancreatic

LYSOSOMES
1. Discovered in 1950 by Rene de Duve (Nobel prize 1974), lysosomes are tiny organelles. Solid wastes of a township are usually decomposed in incinerators. Inside a cell, such a process is taking place within the lysosomes. They are bags of enzymes. Clinical applications of lysosomes are shown in Box 2.1.
2. Endocytic vesicles and phagosomes are fused with lysosome (primary) to form the secondary lysosome or digestive vacuole. Foreign particles are progressively digested inside these vacuoles. Completely hydrolysed products are utilized by the cell. As long as the lysosomal membrane is intact, the encapsulated enzymes can act only locally. But when the membrane is disrupted, the released enzymes can hydrolyse external substrates, leading to tissue damage.
3. The lysosomal enzymes have an optimum pH around 5. These enzymes are
   a. Polysaccharide hydrolysing enzymes (alpha-glucosidase, alpha-fucosidase, beta-galactosidase, alpha-mannosidase, beta-glucuronidase, hyaluronidase, aryl sulfatase, lysozyme)
   b. Protein hydrolysing enzymes (cathepsins, collagenase, elastase, peptidases)
   c. Nucleic acid hydrolysing enzymes (ribonuclease, deoxyribonuclease)
   d. Lipid hydrolysing enzymes (fatty acyl esterase, phospholipases)

PEROXISOMES
1. The peroxisomes have a granular matrix. They are of 0.3–1.5 μm in diameter. They contain peroxidases and catalase. They are prominent in leukocytes and platelets.
2. Peroxidation of polyunsaturated fatty acids in vivo may lead to hydroperoxide formation, R-OOH → R-OO•. The free radicals damage molecules, cell membranes, tissues and genes. (Chapter 20).
3. Catalase and peroxidase are the enzymes present in peroxisomes which will destroy the unwanted peroxides and other free radicals. Clinical applications of peroxisomes are shown in Box 2.2.

MITOCHONDRIA
1. They are spherical, oval or rod-like bodies, about 0.5–1 μm in diameter and up to 7 μm in length

Box 2.1. Clinical Applications of Lysosomes

1. In gout, urate crystals are deposited around knee joints (Chapter 39). These crystals when phagocytosed, cause physical damage to lysosomes and release of enzymes. Inflammation and arthritis result.
2. Following cell death, the lysosomes rupture releasing the hydrolytic enzymes which bring about postmortem autolysis.
3. Lysosomal proteases, cathepsins are implicated in tumor metastasis. Cathepsins are normally restricted to the interior of lysosomes, but certain cancer cells liberate the cathepsins out of the cells. Then cathepsins degrade the basal lamina by hydrolysing collagen and elastin, so that other tumor cells can travel out to form distant metastasis.
4. There are a few genetic diseases, where lysosomal enzymes are deficient or absent. This leads to accumulation of lipids or polysaccharides (Chapters 10 and 13).
5. Silicosis results from inhalation of silica particles into the lungs which are taken up by phagocytes. Lysosomal membrane ruptures, releasing the enzymes. This stimulates fibroblast to proliferate and deposit collagen fibers, resulting in fibrosis and decreased lungs elasticity.
6. Inclusion cell (I-cell) disease is a rare condition in which lysosomes lack in enzymes, but they are seen in blood. This means that the enzymes are synthesized, but are not able to reach the correct site. It is shown that mannose-6-phosphate is the marker to target the nascent enzymes to lysosomes. In these persons, the carbohydrate units are not added to the enzyme. Mannose-6-phosphate-deficient enzymes cannot reach their destination (protein targeting defect).
Erythrocytes do not contain mitochondria. The tail of spermatozoa is fully packed with mitochondria.

2. Mitochondria are the powerhouse of the cell, where energy released from oxidation of food stuffs is trapped as chemical energy in the form of ATP (Chapter 19). Metabolic functions of mitochondria are shown in Table 2.2.

3. Mitochondria have two membranes. The inner membrane convolutes into folds or cristae (Fig. 2.3). The inner mitochondrial membrane contains the enzymes of electron transport chain (Chapter 19). The fluid matrix contains the enzymes of citric acid cycle, urea cycle and heme synthesis.

4. Cytochrome P-450 system present in mitochondrial inner membrane is involved in steroidogenesis (Chapter 46). Superoxide dismutase is present in cytosol and mitochondria (Chapter 20).

5. Mitochondria also contain specific DNA. The integral inner membrane proteins, are made by mitochondrial protein synthesising machinery. However the majority of proteins, especially of outer membrane are synthesised under the control of cellular DNA. Mitochondrial ribosomes are different from cellular ribosomes. Antibiotics inhibiting bacterial protein synthesis do not affect cellular processes, but do inhibit mitochondrial protein biosynthesis (Chapter 41).

6. Taking into consideration such evidences, it is assumed that mitochondria are parasites which entered into cells at a time when multicellular organisms were being evolved. These parasites provided energy in large quantities giving an evolutionary advantage to the cell; the cell gave protection to these parasites. This perfect symbiosis, in turn, evolved into a cellular organelle of mitochondria.

7. A summary of functions of organelles is given in Table 2.2 and Box 2.3.

---

**Box 2.2. Peroxisomal Deficiency Diseases**

1. Deficiency of peroxisomal matrix proteins can lead to adrenoleukodystrophy (ALD) (Brown-Schilder’s disease) characterized by progressive degeneration of liver, kidney and brain. It is a rare autosomal recessive condition. The defect is due to insufficient oxidation of very long chain fatty acids (VLCFA) by peroxisomes (see Chapter 13).

2. In Zellweger syndrome, proteins are not transported into the peroxisomes. This leads to formation of empty peroxisomes or peroxisomal ghosts inside the cells. Protein targeting defects are described in Chapter 41.

3. Primary hyperoxaluria is due to the defective peroxisomal metabolism of glyoxalate derived from glycine (Chapter 15).
Chapter 2: Subcellular Organelles and Cell Membranes

**PLASMA MEMBRANE**

1. The plasma membrane separates the cell from the external environment. It has highly selective permeability properties so that the entry and exit of compounds are regulated. The cellular metabolism is in turn influenced and probably regulated by the membrane. The membrane is metabolically very active.

2. The enzyme, nucleotide phosphatase (5' nucleotidase) and alkaline phosphatase are seen on the outer part of cell membrane; they are therefore called **ecto-enzymes**.

3. Membranes are mainly made up of lipids, proteins and small amount of carbohydrates. The contents of these compounds vary according to the nature of the membrane. The carbohydrates are present as glycoproteins and glycolipids. Phospholipids are the most common lipids present and they are amphipathic in nature. Cell membranes also contain cholesterol.

4. **Fluid Mosaic Model**

   The lipid bilayer was originally proposed by Davson and Danielle in 1935. Later, the structure of the biomembranes was described as a fluid mosaic model (Singer and Nicolson, 1972).

4-A. The phospholipids are arranged in bilayers with the polar head groups oriented towards the extracellular side and the cytoplasmic side with a hydrophobic core (Fig. 2.4A). The distribution of the phospholipids is such that choline containing phospholipids are mainly in the external layer and ethanolamine and serine containing phospholipids in the inner layer.

4-B. Each leaflet is 25 Å thick, with the head portion 10 Å and tail 15 Å thick. The total thickness is about 50 to 80 Å.

4-C. The lipid bilayer shows free lateral movement of its components, hence the membrane is said to be **fluid in nature**. Fluidity enables the membrane to perform endocytosis and exocytosis.

4-D. However, the components do not freely move from inner to outer layer, or outer to inner layer (flip-flop movement is restricted). During apoptosis (programmed cell death), flip-flop movement occurs.

   This Flip-flop movement is catalyzed by enzymes. **Flippases** catalyse the transfer of amino phospholipids across the membrane. **Floppases** catalyse the outward directed movement which is ATP dependent. This is mainly seen in the role of ABC proteins mediating the efflux of cholesterol and the extrusion of drugs from cells. The MDR (multi drug resistance) associated p-glycoprotein is a floppase. Ernst Ruska designed the first electron microscope in 1939. Gerd Binning and Heinrich Rohrer introduced the scanning electron microscopy in 1981 by which the outer and inner layers of membranes could be visualized separately. All the three workers were awarded Nobel prize in 1986.

4-E. The cholesterol content of the membrane alters the fluidity of the membrane. When cholesterol concentration increases, the membrane becomes less fluid on the outer surface, but more fluid in the hydrophobic core. The effect of cholesterol on membrane fluidity is different at different temperatures. At temperature below the Tm cholesterol increases fluidity and thereby permeability of the membrane. At temperatures above the Tm, cholesterol decreases fluidity.

   In spur cell anemia and alcoholic cirrhosis membrane studies have revealed the role of excess cholesterol. The decrease in membrane fluidity may affect the activities of receptors and ion channels. This has been implicated in conditions like LCAT deficiency, Alzheimer’s disease and hypertension.

   Fluidity of cellular membranes responds to variations in diet and physiological states. Increased release of reactive oxygen species (ROS), increase in cytosolic calcium and lipid peroxidation have been found to adversely affect membrane fluidity. Anesthetics may act by changing membrane fluidity.

4-F. The nature of the fatty acids also affects the fluidity of the membrane, the more **unsaturated cis fatty acids** increase the fluidity.

   The fluidity of the membrane is maintained by the length of the hydrocarbon chain, degree of unsaturation and nature of the polar head groups. Trans fatty acids (TFA) decrease the fluidity of membranes due to close packing of hydrocarbon chains. Cis double bonds create a kink in the hydrocarbon chain and have a marked effect on fluidity. Second OH group of

4-C. The lipid bilayer shows free lateral movement of its components, hence the membrane is said to be **fluid in nature**. Fluidity enables the membrane to perform endocytosis and exocytosis.

4-D. However, the components do not freely move from inner to outer layer, or outer to inner layer (flip-flop movement is restricted). During apoptosis (programmed cell death), flip-flop movement occurs.

   This Flip-flop movement is catalyzed by enzymes. **Flippases** catalyse the transfer of amino phospholipids across the membrane. **Floppases** catalyse the outward directed movement which is ATP dependent. This is mainly seen in the role of ABC proteins mediating the efflux of cholesterol and the extrusion of drugs from cells. The MDR (multi drug resistance) associated p-glycoprotein is a floppase. Ernst Ruska designed the first electron microscope in 1939. Gerd Binning and Heinrich Rohrer introduced the scanning electron microscopy in 1981 by which the outer and inner layers of membranes could be visualized separately. All the three workers were awarded Nobel prize in 1986.

4-E. The cholesterol content of the membrane alters the fluidity of the membrane. When cholesterol concentration increases, the membrane becomes less fluid on the outer surface, but more fluid in the hydrophobic core. The effect of cholesterol on membrane fluidity is different at different temperatures. At temperature below the Tm cholesterol increases fluidity and there by permeability of the membrane. At temperatures above the Tm, cholesterol decreases fluidity.

   In spur cell anemia and alcoholic cirrhosis membrane studies have revealed the role of excess cholesterol. The decrease in membrane fluidity may affect the activities of receptors and ion channels. This has been implicated in conditions like LCAT deficiency, Alzheimer’s disease and hypertension.

   Fluidity of cellular membranes responds to variations in diet and physiological states. Increased release of reactive oxygen species (ROS), increase in cytosolic calcium and lipid peroxidation have been found to adversely affect membrane fluidity. Anesthetics may act by changing membrane fluidity.

4-F. The nature of the fatty acids also affects the fluidity of the membrane, the more **unsaturated cis fatty acids** increase the fluidity.

   The fluidity of the membrane is maintained by the length of the hydrocarbon chain, degree of unsaturation and nature of the polar head groups. Trans fatty acids (TFA) decrease the fluidity of membranes due to close packing of hydrocarbon chains. Cis double bonds create a kink in the hydrocarbon chain and have a marked effect on fluidity. Second OH group of
glycerol in membrane phospholipids is often esterified to an unsaturated fatty acid, mono unsaturated oleic or polyunsaturated linoleic, linolenic or arachidonic.

The nature of fatty acids and cholesterol content varies depending on diet. A higher proportion of PUFA which increases the fluidity favors the binding of insulin to its receptor, a trans membrane protein.

5. Membrane Proteins

5-A. The peripheral proteins exist on the surfaces of the bilayer (Fig. 2.4B). They are attached by ionic and polar bonds to polar heads of the lipids.

5-B. Anchoring of proteins to lipid bilayers: Several peripheral membrane proteins are tethered to the membranes by covalent linkage with the membrane lipids. Since the lipids are inserted into the hydrophobic core, the proteins are firmly anchored. A typical form of linkage is the one involving phosphatidyl inositol which is attached to a glycan. This glycan unit has ethanolamine, phosphate and several carbohydrate residues. This glycan chain includes a glucose covalently attached to the C terminus of a protein by the ethanolamine and to the phosphatidyl inositol by the glucosamine. The fatty acyl groups of the phosphatidyl inositol diphosphate (PIP2) are firmly inserted into the lipid membrane thus anchoring the protein. This is referred to as glycosyl phosphatidyl inositol (GPI) anchor.

5-C. Microdomains on membranes: GPI anchored proteins are often attached to the external surface of plasma membrane at microdomains called lipid rafts. They are areas on the membrane having predominantly glycosphingolipids and cholesterol. The localization and activity of the protein can be regulated by anchoring and release. Defective GPI anchors are implicated in PNH (paroxysmal nocturnal hemoglobinuria). Lipid rafts have a role in endocytosis, G protein signaling and binding of viral pathogens. The GPI anchors that tether proteins to the membrane are also seen at the lipid rafts. Membrane proteins may be anchored by covalent bonding, palmitoylation and myristoylation.

5-D. Caveolae are flask shaped indentations on the areas of lipid rafts that are involved in membrane transport and signal transduction. Caveolae contain the protein caveolin, along with other receptor proteins. Transport of macromolecules (IgA) from the luminal side occurs by caveolae mediated transcytosis. The endocytosis of cholesterol containing lipoproteins may be caveolae mediated. Similarly the fusion and budding of viral particles are also mediated by caveolae.

5-E. The integral membrane proteins are deeply embedded in the bilayer and are attached by hydrophobic bonds or van der Waals forces.

5-F. Some of the integral membrane proteins span the whole bilayer and they are called transmembrane proteins (Fig. 2.4). The hydrophobic side chains of the amino acids are embedded in the hydrophobic central core of the membrane. The transmembrane proteins can serve as receptors (for hormones, growth factors, neurotransmitters), tissue specific antigens, ion channels, membrane-based enzymes, etc.

Bacterial Cell Wall

Prokaryotic (bacterial) cells as well as plant cells have a cell wall surrounding the plasma membrane; this cell wall provides mechanical strength to withstand high osmotic pressure. Animal cells are devoid of the cell wall; they have only plasma membrane. Major constituent of bacterial cell wall is a heteropolysaccharide, consisting of repeating units of N-acetyl muramic acid (NAM) and N-acetyl glucosamine (NAG). This polysaccharide provides mechanical strength to the plasma membrane. Synthesis of this complex polysaccharide is blocked by penicillin. This inhibition is responsible for the bactericidal action of penicillin.

SPECIALISED MEMBRANE STRUCTURES

Tight Junction

When two cells are in close approximation, in certain areas, instead of 4 layers, only 3 layers of plasma membranes are seen. This tight junction permits calcium and other small molecules to pass through from one cell to another through narrow hydrophilic pores. Some sort of communication between cells thus results. Absence of tight junction is implicated in loss of contact inhibition in cancer cells (Chapter 51). Tight junctions also seal off subepithelial spaces of organs from the lumen. They contain specialized proteins such as occludin, claudins and other adhesion molecules.
Myelin Sheath
It is made up of the membrane of Schwann cells (Theodor Schwann, 1858) condensed and spiraled many times around the central axon. The cytoplasm of Schwann cells is squeezed to one side of the cell. Myelin is composed of sphingomyelin, cholesterol and cerebroside. Myelin sheaths thin out in certain regions (Node of Ranvier) (Anotoine Ranvier, 1878). Due to this arrangement, the propagation of nerve impulse is wave-like; and the speed of propagation is also increased. Upon stimulation, there is rapid influx of sodium and calcium, so that depolarization occurs. Voltage gradient is quickly regained by ion pumps. The ions flow in and out of membrane only where membrane is free of insulation; hence the wave-like propagation of impulse. In multiple sclerosis, demyelination occurs at discrete areas, velocity of nerve impulse is reduced, leading to motor and sensory deficits.

Microvilli
Microvilli of intestinal epithelial cells and pseudopodia of macrophages are produced by membrane evagination. This is due to the fluid nature of membranes.

Membranes of Organelle
Membranes of endoplasmic reticulum, nucleus, lysosomes and outer layer of mitochondria may be considered as variants of plasma membrane. Percentage of protein content varies from 20% in myelin sheath to over 70% in the inner membranes of mitochondria.

Cytoskeleton
Human body is supported by the skeletal system; similarly the structure of a cell is maintained by the cytoskeleton present underneath the plasma membrane. The cytoskeleton is responsible for the shape of the cell, its motility and chromosomal movements during cell division. The cytoskeleton is made up of a network of microtubules (Fig. 2.1) and microfilaments, which contain the proteins spectrin and ankyrin. Tubules consist of polymers of tubulin.

Molecular Motors
Proteins that are responsible for co-ordinated movements in tissues and cells are referred to as molecular motors. These may be ATP driven as in the case of the contractile proteins; actin and myosin in muscle as well as dyenin and tubulin in cilia and flagella. Kinesin which mediates movement of vesicles on microtubules also requires ATP.

TRANSPORT MECHANISMS
The permeability of substances across cell membrane is dependent on their solubility in lipids and not on their molecular size. Water soluble compounds are generally impermeable and require carrier mediated transport. An important function of the membrane is to withhold unwanted molecules, while permitting entry of molecules necessary for cellular metabolism. Transport mechanisms are classified into

1. Passive transport
   1-A. Simple diffusion
   1-B. Facilitated diffusion
   1-C. Ion channels are specialized carrier systems. They allow passage of molecules in accordance with the concentration gradient.

2. Active transport
   3. Pumps can drive molecules against the gradient using energy.

1-A. Simple Diffusion
Solute and gases enter into the cells passively. They are driven by the concentration gradient. The rate of entry is proportional to the solubility of that
solute in the hydrophobic core of the membrane. Simple diffusion occurs from higher to lower concentration. This does not require any energy. However, it is a very slow process.

1-B. Facilitated Diffusion
This is a carrier mediated process (Fig. 2.5). Important features of facilitated diffusion are:

a. The carrier mechanism could be saturated which is similar to the Vmax of enzymes.

b. Structurally similar solutes can competitively inhibit the entry of the solutes.

c. Facilitated diffusion can operate bidirectionally.

d. This mechanism does not require energy but the rate of transport is more rapid than simple diffusion process.

e. The carrier molecules can exist in two conformations, Ping and Pong states. In the pong state, the active sites are exposed to the exterior, when the solutes bind to the specific sites. Then there is a conformational change. In the ping state, the active sites are facing the interior of the cell, where the concentration of the solute is minimal. This will cause the release of the solute molecules and the protein molecule reverts to the pong state. By this mechanism the inward flow is facilitated, but the outward flow is inhibited (Fig. 2.5). Hormones regulate the number of carrier molecules. For example, glucose transport across membrane is by facilitated diffusion involving a family of glucose transporters. Glucose transport is described in detail in Chapter 9.

Aquaporins
They are water channels (Fig. 2.6). They are a family of membrane channel proteins that serve as selective pores through which water crosses the plasma membranes of cells. They form tetramers in the cell membrane, and facilitate the transport of water. They control the water content of cells. Agre and MacKinnon were awarded Nobel prize for chemistry in 2003 for their contributions on aquaporins and water channels. Diseases such as nephrogenic diabetes insipidus is due to impaired function of these channels.

Channelopathies are a group of disorders that result from abnormalities in the proteins forming the ion pores or channels. A few examples are cystic fibrosis (chloride channel), Liddle's syndrome (sodium channel) and periodic paralysis (potassium channel).

1-C. Ion Channels
Membranes have special devices called ion channels (Fig. 2.7). Ion channels are transmembrane proteins that allow the selective entry of

Box 2.4. Salient Features of Ion Channels

1. They are transmembrane proteins
2. Selective for one particular ion
3. Regulation of activity is done by voltage-gated, ligand-gated or mechanically gated mechanisms
4. Different channels are available for Na⁺, K⁺, Ca²⁺ and Cl⁻
5. Transport through the channel is very quick
various ions. Salient features are enumerated in Box 2.4. These channels are for quick transport of electrolytes such as Ca$$^{2+}$$, K$$^+$$, Na$$^+$$ and Cl$$^-$$ . These are selective ion conductive pores. Ion channels are specialized protein molecules that span the membranes. The channels generally remain closed, but in response to stimulus, they open allowing rapid flux of ions down the gradient. This may be compared to opening of the gate of a cinema house, when people rush to enter in. Hence this regulation is named as "gated". Such ion channels are important for nerve impulse propagation, synaptic transmission and secretion of biologically active substances from the cells. Ion channels are different from ion transport pumps described below.

### Ligand Gated Channels

Ligand gated channels are opened by binding of effectors. The binding of a ligand to a receptor site on the channel results in the opening (or closing) of the channel (Fig. 2.11). The ligand may be an extracellular signalling molecule or an intracellular messenger. Clinical applications of channels are shown in Box 2.5.

#### a. Acetyl choline receptor
(Fig. 2.9) is the best example for ligand gated ion channel. It is present in postsynaptic membrane. It is a complex of 5 subunits, consisting of acetyl choline binding site and the ion channel. Acetyl choline released from the presynaptic region binds with the receptors on the postsynaptic region, which triggers opening of the channel and influx of Na$$^+$$ . This generates an action potential in the postsynaptic nerve. The channel opens only for a millisecond, because the acetyl choline is rapidly degraded by acetyl cholinesterase.

#### b. Calcium channels
Under appropriate stimuli calcium channels are opened in the sarcoplasmic reticulum membrane, leading to an elevated calcium level in the cytosol of muscle cells. Calcium channel blockers are therefore widely used in the management of hypertension.

#### c. Amelogenin
a protein present in enamel of teeth has hydrophobic residues on the outside. A 27 amino acid portion of amelogenin functions as a calcium channel.

**Box 2.5. Clinical Applications of Channels**

1. **Sodium Channels:** Local anesthetics such as **procaine** act on sodium channels both as blockers and on gating mechanisms to hold the channel in an inactivated state. Point mutation in sodium channel leads to myotonia, characterized by increased muscle excitability and contractility.

2. In **Liddle’s disease**, the sodium channels in the renal epithelium are mutated, resulting in excessive sodium reabsorption, water retention and elevated blood pressure.

3. **Potassium channel** mutations in “Long QT syndrome” leads to inherited cardiac arrhythmia, where repolarization of the ventricle is delayed, resulting in prolonged QT intervals in ECG.

4. **Chloride channels:** The role of GABA and glycine as inhibitory neuro-transmitters is attributed to their ability to open the chloride channels at the postsynaptic membranes.

5. **Cystic fibrosis** is due to certain mutations in the CFTR gene (cystic fibrosis transmembrane regulator protein), which is a chloride transporter.

6. **Retina:** The excitation of retinal rods by a photon is by closing of cation specific channels resulting in hyperpolarization of the rod cell membrane. This light induced hyperpolarization is the major event in visual excitation (see, Chapter 33).

---

**Fig. 2.11.** Left side, voltaged gated channels; on the right side, ligand gated channels; closed and open positions.
Phosphorylation of a serine residue of the protein opens the calcium channel, through which calcium ions zoom through and are funnelled to the mineralization front. The amelogenin is used for the formation of calcium hydroxyapatite crystals.

**Voltage Gated Channels**

Voltage gated channels are opened by membrane depolarization (Fig. 2.11). The channel is usually closed in the ground state. The membrane potential change (voltage difference) switches the ion channel to open, lasting less than 25 milliseconds.

In voltage gated channels, the channels open or close in response to changes in membrane potential. They pass from closed through open to inactivated state on depolarization. Once in the inactivated state, a channel cannot re-open until it has been reprimed by repolarization of the membrane.

Voltage gated sodium channels and voltage gated potassium channels are the common examples. These are seen in nerve cells and are involved in the conduction of nerve impulses.

Ion channels allow passage of molecules in accordance with the concentration gradient. Ion pumps can transport molecules against the gradient.

**Ionophores**

They are membrane shuttles for specific ions. They transport antibiotics. Ionophores increase the permeability of membrane to ions by acting as channel formers. The two types of ionophores are; mobile ion carriers (e.g. Valinomycin) and channel formers (e.g. Gramicidin). They are produced by certain microorganisms and are used as antibiotics. When cells of higher organisms are exposed to ionophores, the ion gradient is dissipated. Valinomycin allows potassium to permeate mitochondria and so it dissipates the proton gradient; hence it acts as an uncoupler of electron transport chain (Chapter 19).

**2. Active Transport**

The salient features of active transport are:

- This form of transport requires energy. About 40% of the total energy expenditure in a cell is used for the active transport system.
- The active transport is unidirectional.
- It requires specialized integral proteins called transporters.
- The transport system is saturated at higher concentrations of solutes.
- The transporters are susceptible to inhibition by specific organic or inorganic compounds. General reaction is depicted in Figure 2.8.

**2-A. Sodium Pump**

It is the best example for active transport. Cell has low intracellular sodium; but concentration of potassium inside the cell is very high. This is maintained by the sodium–potassium activated ATPase, generally called as sodium pump. The ATPase is an integral protein of the membrane (Fig. 2.10). It has binding sites for ATP and sodium on the inner side and the potassium binding site is located outside the membrane. It is made up of two pairs of unequal subunits $\alpha_2 \beta_2$. Both subunits of the pump (alpha and beta) span the whole thickness of membrane. Details are shown in Fig. 2.10. Clinical applications of sodium pump are shown in Box 2.6.

**2-B. Calcium Pump**

An ATP dependent calcium pump also functions to regulate muscle contraction. A specialized membrane system called sarcoplasmic reticulum is found in skeletal muscles which regulates the $Ca^{++}$ concentration around muscle fibers.

In resting muscle the concentration of $Ca^{++}$ around muscle fibers is low. But stimulation by a nerve impulse results in a sudden release of large amounts of $Ca^{++}$. This would trigger muscle contraction. The function of calcium pump is to remove cytosolic calcium and maintain low

**Box 2.6. Clinical Applications of Sodium Pump**

Cardiotonic drugs like digoxin and ouabain bind to the alpha-subunit and act as competitive inhibitor of potassium ion binding to the pump. Inhibition of the pump leads to an increase in Na* level inside the cell and extrusion of Ca** from the myocardial cell. This would enhance the contractility of the cardiac muscle and so improve the function of the heart.
cytosolic concentration, so that muscle can receive the next signal. For each ATP hydrolysed, 2Ca^{++} ions are transported.

**Uniport, Symport and Antiport**
Transport systems are classified as uniport, symport and antiport systems (Fig. 2.12).

1. **Uniport system** carries single solute across the membrane, e.g. glucose transporter in most of the cells. Calcium pump is another example.

2. If the transfer of one molecule depends on simultaneous or sequential transfer of another molecule, it is called **co-transport** system. The active transport may be coupled with energy indirectly. Here, movement of the substance against a concentration gradient is coupled with movement of a second substance down the concentration gradient; the second molecule being already concentrated within the cell by an energy requiring process.

3. The co-transport system may either be a **symport** or an **antiport**. In **symport**, (Fig. 2.12) the transporter carries two solutes in the same direction across the membrane, e.g. sodium dependent glucose transporter (Chapter 8). **Phlorhizin**, an inhibitor of sodium-dependent co-transport of glucose, especially in the proximal convoluted tubules of kidney, produces renal damage and results in renal glycosuria. Amino acid transport is another example for symport.

4. The **antiport** system (Fig. 2.12) carries two solutes or ions in opposite direction, e.g. sodium pump (Fig. 2.10) or chloride-bicarbonate exchange in RBC (Chapter 22). Features of different types of transport modalities are summarized in Table 2.3.

**Clinical Applications**
In **Hartnup's disease**, transport mechanisms for amino acids are defective in intestine and renal tubules (Chapter 17). In **cystinuria**, renal reabsorption of cysteine is abnormal (Chapter 16). Renal reabsorption of phosphate is decreased in **vitamin D** resistant rickets (Chapter 33). Diseases due to abnormalities of transport systems include familial hypercholesterolemia, cystic fibrosis, congenital long QT syndrome, Wilson disease, I-cell disease, hereditary spherocytosis and paroxysmal nocturnal hemoglobinuria, etc.

---

**Fig. 2.13. Exocytosis**

**Fig. 2.14. Different types of endocytosis.** Left side, phagocytosis; middle, pinocytosis; right side, receptor mediated endocytosis.
Secretory Vesicles and Exocytosis
Under appropriate stimuli, the secretory vesicles or vacuoles move towards and fuse with the plasma membrane. This movement is created by cytoplasmic contractile elements; the microtubule system. The inner membrane of the vesicle fuses with outer plasma membrane, while cytoplasmic side of vesicle fuses with cytoplasmic side of plasma membrane. Thus the contents of vesicles are externalized. This process is called exocytosis or reverse pinocytosis. Release of trypsinogen by pancreatic acinar cells; release of insulin by beta cells of Langerhans and release of acetyl choline by presynaptic cholinergic nerves are examples of exocytosis (Fig. 2.13). Often, hormones are the signal for exocytosis, which leads to calcium ion changes, triggering the exocytosis.

Endocytosis
Endocytosis is the mechanism by which cells internalize extracellular macromolecules, to form an endocytic vesicle. This requires energy in the form of ATP as well as calcium ions in the extracellular fluid. Cytoplasmic contractile elements take part in this movement. In general, plasma membrane is invaginated, enclosing the matter. This forms the endocytic vesicle. The endocytosis may be pinocytosis or phagocytosis or receptor mediated endocytosis (Fig. 2.14).

Pinocytosis
Pinocytosis literally means ‘drinking by the cell’. Cells take up fluid by this method (Fig. 2.14). The fluid phase pinocytosis is a nonselective process.

Receptor Mediated Endocytosis
The selective or adsorptive pinocytosis is receptor mediated; also called as absorptive pinocytosis. Low Density Lipoprotein (LDL) is a good example. LDL binds to the LDL receptor and the complex is later internalized. The cytoplasmic side of these vesicles are coated with filaments; mainly composed of Clathrin. These are called Clathrin coated pits (Fig. 2.14). Absorption of cholesterol by clathrin coated pit is shown in Figure 12.13. After the LDL-receptor complex is internalized, the receptor molecules are released back to cell surface; but the LDL is degraded by lysosomal enzymes. Several hormones are also taken up by the cells by receptor-mediated mechanism. The protein, Dynamin which has GTPase activity, is necessary for the internalisation of clathrin coated pits. Many viruses get attached to their specific receptors on the cell membranes. Examples are Influenza virus, Hepatitis B virus, polio virus and HIV. They are taken up by caveolae mediated processes. Caveolae mediated endocytosis is also known as potocytosis.

Phagocytosis
The term is derived from the Greek word "phagein" which means to eat. It is the engulfment of large particles such as bacteria by macrophages and granulocytes. They extend pseudopodia and surround the particles to form phagosomes (Fig. 2.14). Phagosomes later fuse with lysosomes to form phagolysosomes, inside which the particles are digested. An active macrophage can ingest 25% of their volume per hour. In this process, 3% of plasma membrane is internalized per minute. The biochemical events accompanying phagocytosis is described as respiratory burst (Chapter 20).
Proteins are of paramount importance for biological systems. All the major structural and functional aspects of the body are carried out by protein molecules. All proteins are polymers of amino acids. Proteins are composed of a number of amino acids linked by peptide bonds.

Although about 300 amino acids occur in nature, only 20 of them are seen in human body. Most of the amino acids (except proline) are alpha amino acids, which means that the amino group is attached to the same carbon atom to which the carboxyl group is attached (Fig. 3.1).

CLASSIFICATION OF AMINO ACIDS

1. Based on structure

1-A. Aliphatic amino acids
   a. Mono amino mono carboxylic acids:
      • Simple amino acids: Glycine, Alanine (Fig. 3.2)
      • Branched chain amino acids: Valine, Leucine, Isoleucine (Fig. 3.3)
      • Hydroxy amino acids: Serine, Threonine (Fig. 3.4)
      • Sulphur containing amino acids: Cysteine, Methionine (Fig. 3.5)
      • Amino acids with amide group: Asparagine, Glutamine (Fig. 3.6)
   b. Mono amino dicarboxylic acids: Aspartic acid, Glutamic acid (Fig. 3.7)
c. **Di basic mono carboxylic acids:** Lysine, Arginine (Fig. 3.8)

1-B. **Aromatic amino acids:**
Phenylalanine, Tyrosine (Fig. 3.9)

1-C. **Heterocyclic amino acids:**
Tryptophan (Fig. 3.10), Histidine (Fig. 3.11)

1-D. **Imino acid:** Proline (Fig. 3.11)

1-E. **Derived amino acids:**

1-E-i. **Derived amino acids found in proteins:** After the synthesis of proteins, some of the amino acids are modified, e.g. hydroxy proline (Fig. 3.12) and hydroxy lysine are important components of collagen. Gamma carboxylation of glutamic acid residues of proteins is important for clotting process (Fig. 3.12). In ribosomal proteins and in histones, amino acids are extensively methylated and acetylated.

1-E-ii. **Derived amino acids not seen in proteins (Non-protein amino acids):**
Some derived amino acids are seen free in cells, e.g. Ornithine (Fig. 3.12), Citrulline, Homocysteine. These are produced during the metabolism of amino acids. Thyroxine may be considered as derived from tyrosine.

1-E-iii. **Non-alpha amino acids:**
Gamma amino butyric acid (GABA) is derived from glutamic acid. Beta alanine, where amino group is in beta position, is a constituent of pantothenic acid (vitamin) and co-enzyme A.

Each amino acid will have three-letter and one-letter abbreviations which are shown in Table 3.1 as well as in Figs 3.2 to 3.11. Sometimes asparagine/aspartic acid may not be separately identified, for which 3-letter abbreviation is Asx and 1-letter abbreviation is B.

Similarly Glx or Z stands for glutamine/glutamic acid.

### Special Groups in Amino Acids

In the figures, special groups are shaded. Arginine contains guanidinium group; Phenyl alanine (benzene); Tyrosine (phenol); Tryptophan (indole); Histidine (imidazole); and Proline (pyrrolidine) (Table 3.1). Proline has a secondary amino group, and hence it is an imino acid.

### 2. CLASSIFICATION BASED ON SIDE CHAIN

2-A. **Amino acids having nonpolar side chains:**
These include Alanine, Valine, Leucine, Isoleucine, Methionine, Proline, Phenylalanine and Tryptophan.
These groups are hydrophobic (water repellant) and lipophilic. Therefore, the parts of proteins made up of these amino acids will be hydrophobic in nature.

2-B. Amino acids having uncharged or non-ionic polar side chains:
Glycine, Serine, Threonine, Cysteine, Tyrosine, Glutamine and Asparagine belong to this group. These amino acids are hydrophilic in nature. (Tyrosine and Cysteine may show hydrophobic character when present in the interior of the protein).

2-C. Amino acids having charged or ionic polar side chains (hydrophilic):
C-a. Acidic amino acids: They have a negative charge on the R group: Aspartic acid and Glutamic acid (Tyrosine is mildly acidic).
C-b. Basic amino acids: They have a positive charge on the R group: Lysine, Arginine and Histidine.

3. CLASSIFICATION BASED ON METABOLISM
3-A. Purely Ketogenic
Leucine is purely ketogenic because it is converted to ketone bodies (Fig.17.14).

3-B. Ketogenic and Glucogenic
Lysine, Isoleucine, Phenylalanine, Tyrosine and Tryptophan are partially ketogenic and partially glucogenic. How ever in humans lysine is predominantly ketogenic. During metabolism, part of the carbon skeleton of these amino acids will enter the ketogenic pathway and the other part to glucogenic pathway (see Fig.17.14).

3-C. Purely Glucogenic
All the remaining 14 amino acids are purely glucogenic as they enter only into the glucogenic pathway (See Chapter 17).

4. CLASSIFICATION BASED ON NUTRITIONAL REQUIREMENTS
4-A. Essential or Indispensable
The amino acids may further be classified according to their essentiality for growth. Thus Isoleucine, Leucine, Threonine, Lysine, Methionine, Phenylalanine, Tryptophan, and Valine are essential amino acids. Their carbon skeleton cannot be synthesized by human beings and so preformed amino acids are to be taken in food for normal growth. See memory aid in Box 3.1.

4-B. Partially essential or Semi-essential
Histidine and arginine are semi-indispensable amino acids. Growing children require them in food. But they are not essential for the adult individual.

4-C. Non-essential or Dispensable
The remaining 10 amino acids are non-essential, because their carbon skeleton can be synthesized

---

**Box 3.1. Memory Aid for Essential Amino Acids**

"Any Help In Learning These Little Molecules Proves Truely Valuable"
This stands for Arginine, Histidine, Isoleucine, Leucine, Threonine, Lysine, Methionine, Phenylalanine, Tryptophan and Valine in that order.

Arginine and Histidine are semi-essential amino acids; while others are essential
Box 3.2. Selenocysteine as the 21st amino acid

21st century witnesses the addition of selenocysteine as the 21st amino acid present in human proteins. An amino acid is given the individual status, when it is incorporated as such into proteins during protein biosynthesis, and having a separate codon. Selenocysteine is present in some enzymes. Instead of SH (sulfhydryl) group in cysteine, SeH (selenium) is present in selenocysteine. It is abbreviated as SeCys or SeC. Details are given in Chapter 15, under serine.

Similarly pyrrolysine (Pyl) is known as the 22nd amino acid. Pyrrolysine is a lysine in an amide linkage to substituted-pyrroline-5-carboxylate. It is present in methyl transferase enzymes of certain bacteria. Both SeC and Pyl are encoded by codons that normally function as stop signals.

by the body. However, they are also required for normal protein synthesis. All body proteins do contain all the non-essential amino acids.

Naming (Numbering) of Carbon Atoms

Carbon atoms in amino acids in sequence are named with letters of Greek alphabets, starting from the carbon atom to which carboxyl group is attached. As examples, naming of glutamic acid is shown in figure 3.7 and that of lysine is shown in Figure 3.8.

Properties of Amino Acids

Glycine, alanine, valine, serine, tryptophan, histidine and proline are sweet in taste; leucine is tasteless; while isoleucine and arginine are bitter. Sodium glutamate is a flavoring agent. Aspartame, an artificial sweetener contains aspartic acid and phenyl alanine. All amino acids have high melting points (more than 200°C). All amino acids are soluble in water and alcohol (polar solvents); but insoluble in nonpolar solvents (benzene).

A. Ampholyte and Iso-electric Point

1. Amino acids can exist as ampholytes or zwitterions (German word "zwitter" = hybrid) in solution, depending on the pH of the medium.

2. The pH at which the molecule carries no net charge is known as iso-electric point or isoelectric pH (pl).

3. In acidic solution they are cationic in form and in alkaline solution they behave as anions (Fig. 3.13).

4. At iso-electric point the amino acid will carry no net charge; all the groups are ionized but the charges will cancel each other. Therefore at iso-electric point, there is no mobility in an electrical field. Solubility and buffering capacity will be minimum at iso-electric pH.

5. To such a solution if we add hydrochloric acid drop by drop, at a particular pH, 50% of the molecules are in cationic form and 50% in zwitterion form. This pH is pK1 (with regard to COOH). If more HCl is added, more molecules become cationic in nature and solubility increases.

6. On the other hand, if we titrate the solution from iso-electric point with NaOH, molecules acquire the anionic form. When 50% of molecules are anions, that pH is called pK2 (with respect to NH2).

7. The iso-electric pH (pl) for mono amino mono carboxylic amino acids can be calculated:

Fig. 3.13. Ionic forms of amino acids
Chapter 3; Amino Acids: Structure and Properties

Fig. 3.16. L and D amino acids

B. Optical Activity

1. Amino acids having an asymmetric carbon atom exhibit optical activity. **Asymmetry** arises when 4 different groups are attached to the same carbon atom (Fig. 3.16).

2. Glycine is the simplest amino acid and has no asymmetric carbon atom and therefore shows no optical activity. All others are optically active.

3. The mirror image forms produced with reference to the alpha carbon atom, are called **D and L isomers**.

4. The L-amino acids occur in nature and are therefore called **natural amino acids**. D-amino acids are seen in small amounts in microorganisms and as constituents of certain antibiotics such as Gramicidin-S, Polymyxin, Actinomycin-D and Valinomycin, as well as bacterial cell wall peptidoglycans.

5. Isoleucine and threonine have 2 optically active centers and therefore each has 4 diastereo isomers.

Sorensen’s Formal Titration

Amino acids cannot be exactly titrated. If, for example, 1 ml of 1N solution of glycine is titrated against 1N sodium hydroxide, the alkali requirement will be less than 1 ml. This is because hydrogen ions released by ionization of carboxyl group are partly taken up by the amino group. To circumvent this problem, excess formaldehyde is added to the solution, which converts amino group into neutral dimethylol derivative. Thereafter, titration can be completed to the end point. In the above example, after addition of formaldehyde, exactly 1 ml of 1N sodium hydroxide is utilized in the titration.

**Fig. 3.14. Titration curve of glycine; pH in Y-axis**

\[ \text{pl} = \frac{\text{pK}_1 + \text{pK}_2}{2} \]

\[ \text{e.g. pl of glycine} = \frac{2.4 + 9.8}{2} = 6.1. \]

8. From the graph it is evident that the buffering action is maximum in and around pK1 or at pK2 and minimum at pl (Fig. 3.14)

9. In the case of amino acids having more than two ionizable groups, correspondingly there will be more pK values, e.g. Aspartic acid (Fig. 3.15). The pK values of amino acids are given in Table 3.2. From these values, it can be seen that **at physiological pH of 7.4, both carboxyl and amino groups of amino acids are completely ionized**. Thus to be very correct, zwitterion forms are to be shown as the structures of amino acids.

10. The pK value of imidazolium group of **histidine** is 6.1, and therefore effective as a buffer at the physiological pH of 7.4. The buffering capacity of plasma proteins and hemoglobin is mainly due to histidine residue.

**Fig. 3.15. Ionization of aspartic acid**
GENERAL REACTIONS OF AMINO ACIDS

A. Due to Carboxyl Group

1. Decarboxylation: The amino acids will undergo alpha decarboxylation to form the corresponding amine (Fig. 3.17). Thus some important amines are produced from amino acids. For example,

- Histidine → Histamine + CO₂
- Tyrosine → Tyramine + CO₂
- Tryptophan → Tryptamine + CO₂
- Lysine → Cadaverine + CO₂
- Glutamic acid → Gamma amino butyric acid (GABA) + CO₂

2. Amide Formation: The -COOH group of dicarboxylic amino acids (other than alpha carboxyl) can combine with ammonia to form the corresponding amide. For example,

Aspartic acid + NH₃ → Asparagine
Glutamic acid + NH₃ → Glutamine (Fig. 3.19)

These amides are also components of protein structure. The amide group of glutamine serves as the source of nitrogen for nucleic acid synthesis.

B. Reactions Due to Amino Group

3. Transamination: The alpha amino group of amino acid can be transferred to alpha keto acid to form the corresponding new amino acid and alpha keto acid (Fig. 3.18). This is an important reaction in the body for the inter-conversion of amino acids and for synthesis of non-essential amino acids.

4. Oxidative Deamination: The alpha amino group is removed from the amino acid to form the corresponding keto acid and ammonia (Fig. 14.9).

In the body, Glutamic acid is the most common amino acid to undergo oxidative deamination.

5. Formation of carbamino compound: Carbon dioxide adds to the alpha amino group of amino acids to form carbamino compounds. The reaction occurs at alkaline pH and serves as a mechanism for the transport of carbon dioxide from tissues to the lungs by hemoglobin (Chapter 22).

Hb—NH₂ + CO₂ → Hb—NH—COOH (Carbamino-Hb)

C. Reactions Due to Side Chains

6. Transmethylation: The methyl group of Methionine, after activation, may be transferred to an acceptor which becomes methylated (Chapter 15).

Methionine + Acceptor → Methylated Acceptor + Homocysteine
tyrosine) are neurotransmitters. Gabapentin (an analog of GABA) can pass blood brain barrier and can form GABA in brain. Gabapentin is clinically used to relieve pain.

ii. Histamine (synthesized from histidine) is the mediator of allergic reactions.

iii. Thyroxine (from tyrosine) is an important thyroid hormone.

iv. Cycloserine, a derivative of serine is an antituberculous drug. Azaserine inhibits reactions where amide groups are added, and so acts as an anticancer drug.

v. Histidine residues are important in the buffering activity of proteins.

vi. Ornithine and citrulline are derivatives of arginine, and are essential for urea synthesis.

### PEPTIDE BOND FORMATION

Alpha carboxyl group of one amino acid reacts with alpha amino group of another amino acid to form a peptide bond or CO-NH bridge (Fig. 3.21). Proteins are made by polymerization of amino acids through peptide bonds. Details of protein structures are given in Chapter 4.

#### 7. Ester formation by the OH group: The hydroxy amino acids can form esters with phosphoric acid. In this manner the Serine and Threonine residues of proteins are involved in the formation of phosphoproteins. Similarly these hydroxyl groups can form O-glycosidic bonds with carbohydrate residues to form glycoproteins.

#### 8. Reaction of the amide group: The amide groups of Glutamine and Asparagine can form N-glycosidic bonds with carbohydrate residues to form glycoproteins.

#### 9. Reactions of SH group: Cysteine has a sulphydryl (SH) group and it can form a disulphide (S-S) bond with another cysteine residue. The two cysteine residues can connect two polypeptide chains by the formation of interchain disulphide bonds or links (Fig. 3.20). The dimer formed by two cysteine residues is sometimes called Cystine or Dicysteine.

### Amino Acid Derivatives of Importance

i. Gamma amino butyric acid (GABA, a derivative of glutamic acid) and dopamine (derived from
hydroxy proline will give yellow color with ninhydrin. Amino acids with amide group (glutamine, asparagine) produce a brown color. The ninhydrin reaction may be adopted for qualitative as well as quantitative estimation of amino acids. It is often used for detection of amino acids in chromatography. Proteins do not give a true color reaction; but N-terminal end amino group of protein will also react with ninhydrin, to produce a blue color.

2. **Biuret Reaction**: Cupric ions in an alkaline medium form a violet color with peptide bond nitrogen (Schiff, 1896). This needs a minimum of two peptide bonds, and so individual amino acids and di-peptides will not answer this test. This reaction can be used for quantitative estimation also. The name is derived from the compound biuret (NH₂—CO—NH—CO—NH₂), a condensation product of two urea molecules, which also gives a positive color test. Magnesium and ammonium sulphates interfere with this reaction.

3. **Xanthoproteic test**: The ring systems in phenyl alanine, tyrosine and tryptophan undergo nitration on treatment with concentrated nitric acid when heated (Salkowski, 1888). The end product is yellow in color which is intensified in strong alkaline medium. This reaction causes the yellow stain in skin by nitric acid.

4. **Millon's Test**: The phenol group of phenylalanine and tyrosine containing proteins, when heated with mercuric sulphate in sulphuric acid and sodium nitrite (or, mercurous and mercuric nitrates in nitric acid) form red colored mercury phenolate (Millon, 1849). Chloride interferes with this reaction and so it is not suitable to test for tyrosine in urine samples. Both xanthoproteic and Millon's tests are negative for tapioca (casava) which is deficient in phenylalanine and tyrosine.

5. **Aldehyde tests for tryptophan**: In the Hopkins-Cole test, tryptophan containing protein is mixed with glyoxylic acid, and the mixture is layered over concentrated sulphuric acid. A violet ring at the interface of liquids shows the presence of the indole ring. Formaldehyde and mercuric sulphate is used similarly in **Acree-Rosenheim reaction** to get a violet color. Para-dimethyl-amino-benzaldehyde and strong hydrochloric acid give dark blue color (Ehrlich's reaction). Gelatin with limited tryptophan content will not answer these tests.

6. **Sakaguchi's test for arginine**: Free arginine or arginyl residues in proteins react with alpha-naphthol and alkaline hypobromite to give bright red color. This is due to the guanidinium group.

7. **Sulphur test for cysteine**: When cysteine or cysteine containing proteins are boiled with strong alkali, organic sulphur splits and forms sodium sulphide, which on addition of lead acetate produces lead sulphide as a black precipitate. Methionine does not answer this test because sulphur in methionine is in the thio-ether linkage which is difficult to break. Albumin and keratin will answer sulphur test positively; but casein will give a negative test.

8. **Nitroprusside reaction for SH groups**: Proteins with free sulfhydryl groups give a reddish color with sodium nitroprusside, in ammoniacal solution. Many proteins give a negative, reaction in the native state, but when denatured, reaction will be positive, showing the emergence of free SH groups.

9. **Pauly's test for histidine or tyrosine**: Diazo benzene sulfonic acid reacts with imidazole group of Histidine to form a cherry-red colored diazotised product under alkaline conditions. The same reagent will give an orange red colored product with phenol group of Tyrosine.

Color reactions of amino acids are shown as summary in Table 3.3 The amino acid **Selenocysteine** is described in Box 3.2. Quantitative estimation procedures of proteins are given in Chapter 4.
Proteins: Structure and Function

Amino Acids are Linked by Peptide Bonds

Alpha carboxyl group of one amino acid reacts with alpha amino group of another amino acid to form a peptide bond or CO-NH bridge (Fig. 4.1A).

Proteins are made by polymerisation of amino acids through peptide bonds. Two amino acids are combined to form a dipetide; three amino acids form a tripeptide; four will make a tetrapeptide; a few amino acids together will make an oligopeptide; and combination of 10 to 50 amino acids is called as a polypeptide. By convention, big polypeptide chains containing more than 50 amino acids are called proteins.

In a tripeptide, there are 3 amino acids, but these 3 can be any of the total 20 amino acids. Thus $20^3 = 8000$ different permutations and combinations are possible in a tripeptide. An ordinary protein having about 100 amino acids, will have $20^{100}$ different possibilities. This number is more than the total number of atoms present in the whole universe. Thus, even though there are only 20 amino acids, by changing the sequence of combination of these amino acids, nature produces enormous number of markedly different proteins.

STRUCTURE OF PROTEINS
(Organisation of Proteins)

Proteins have different levels of structural organisation; primary, secondary, tertiary and quaternary.
1. Primary Structure

1-A. Sequence of amino acids in proteins

Protein structure is studied as the primary, secondary, tertiary and quaternary levels (Box 4.1). **Primary structure denotes the number and sequence of amino acids in the protein.** The higher levels of organisation are decided by the primary structure. Each polypeptide chain has a unique amino acid sequence decided by the genes. The primary structure is maintained by the covalent peptide bonds (Fig. 4.1A).

Students should have a clear concept of the term "sequence". See the following example:

Gly - Ala - Val (1)
Gly - Val - Ala (2)

Both the tripeptides shown above contain the same amino acids; but their sequence is altered. When the sequence is changed, the peptide is also different.

1-B. Characteristics of a Peptide Bond

i. The peptide bond is a **partial double bond**.

ii. The C–N bond is ‘trans’ in nature and there is no freedom of rotation because of the partial double bond character. (Fig. 4.1B)

iii. The distance is 1.32Å which is midway between single bond (1.49 Å) and double bond (1.27Å).

iv. The side chains are free to rotate on either side of the peptide bond.

v. The angles of rotation known as **Ramachandran angles**, therefore determine the spatial orientation of the peptide chain (Fig. 4.2). (Dr GN Ramachandran did pioneering work on the structural aspects of proteins during 1950s and 1960s).

1-C. Numbering of Amino Acids in Proteins

i. In a polypeptide chain, at one end there will be one free alpha amino group. This end is called the **amino terminal (N-terminal) end** and the amino acid contributing the alpha-amino group is named as the **first amino acid**. (Fig. 4.3).

ii. Usually the N-terminal amino acid is written on the left hand side when the sequence of the protein is denoted. Incidentally, the bio-synthesis of the protein also starts from the amino terminal end.

iii. The other end of the polypeptide chain is the **carboxy terminal end (C-terminal)**, where there is a free alpha carboxyl group which is contributed by the **last amino acid** (Fig. 4.3). All other alpha amino and alpha carboxyl groups are involved in peptide bond formation.

iv. Amino acid residues in polypeptides are named by changing the suffix "-ine" to "-yl", for example, Glycine to Glycyl. Thus, peptide bonds formed by carboxyl group of glycine with amino group of Alanine, and then carboxyl group of Alanine with amino group of Valine and is called glycyl-alanyl-valine and abbreviated as NH₂-Gly-Ala-Val-COOH or Gly-Ala-Val or simply as GAV

**Box 4.1. Definitions of Levels of Organization**

1. **Primary structure** of protein means the order of amino acids in the polypeptide chain and the location of disulfide bonds, if any.

2. **Secondary structure** is the steric relationship of amino acids, close to each other.

3. **Tertiary structure** denotes the overall arrangement and interrelationship of the various regions, or domains of a single polypeptide chain.

4. **Quaternary structure** results when the proteins consist of two or more polypeptide chains held together by non-covalent forces.
1-D. Branched and Circular Proteins

i. Generally, the polypeptide chains are linear. However, branching points in the chains may be produced by interchain disulphide bridges. The covalent disulphide bonds between different polypeptide chains in the same protein (interchain) or portions of the same polypeptide chain (intrachain) are also part of the primary structure.

ii. Rarely, instead of the alpha COOH group the gamma carboxyl group of glutamic acid may enter into peptide bond formation, e.g. Glutathione (gamma-glutamyl-cysteinyl-glycine) (Fig. 15.19). The term pseudopeptide (or isopeptide) is used to denote such a peptide bond formed by carboxyl group, other than that present in alpha position.

iii. Very rarely, protein may be in a circular form, e.g. Gramicidin.

1-E. Primary Structure of Insulin

As an example of the primary structure of a protein, that of insulin is shown in Fig. 4.4. This was originally described by Sanger in 1955 who received the Nobel prize in 1958.

i. Insulin has two polypeptide chains. The A chain (Glycine chain) has 21 amino acids and B (Phenyl alanine) chain has 30 amino acids.

ii. They are held together by two interchain disulphide bonds (Fig. 4.4). A chain 7th cysteine and B chain 7th cysteine are connected.

Similarly A chain 20th cysteine and B chain 19th cysteine are connected. There is another intrachain disulphide bond between 6th and 11th cysteine residues of A chain.

iii. The species variation is restricted to amino acids in position 8, 9 and 10 in A chain and in C-terminal of B chain (Fig. 4.4). The amino acid sequence has been conserved to a great extent during evolution.

iv. The porcine insulin and human insulin are structurally similar, except the terminal amino acid in B chain (Thr → Ala) (Fig. 4.4). Bovine Insulin may produce antibodies in humans by repeated injections. But de-alaninated porcine

---

**Fig. 4.4. Primary structure of human insulin**

---

**Fig. 4.5. Conversion of Pro-insulin to active insulin. Arrows = site of action of proteolytic enzymes**
Insulin, bearing no antigenic difference from human insulin will not produce antibodies in diabetic patients even after a long-term use. Nowadays human insulin is being produced by recombinant DNA technology.

1-F. Pro-insulin
Beta cells of pancreas synthesize insulin as a prohormone. Proinsulin is a single polypeptide chain with 86 amino acids. Biologically active insulin (2 chains) is formed by removal of the central portion of the pro-insulin before release. The C-peptide (connecting peptide) is also released into the circulation (Fig. 4.5).

1-G. Primary Structure Determines Biological Activity
A protein with a specific primary structure, when put in solution, will automatically form its natural three-dimensional shape. So the higher levels of organization are dependent on the primary structure.

Even a single amino acid change (mutation) in the linear sequence may have profound biological effects on the function. For example, in HbA (normal hemoglobin) the 6th amino acid in the beta chain is glutamic acid; it is changed to valine in HbS (sickle cell anemia).

2. Secondary Structure of Proteins
The term "secondary structure" denotes the configurational relationship between residues which are about 3–4 amino acids apart in the linear sequence (Box 4.2). Secondary and tertiary levels of protein structure are preserved by noncovalent forces or bonds like hydrogen bonds, electrostatic bonds, hydrophobic interactions and van der Waals forces. These forces are described in Chapter 1.

i. A hydrogen bond is a weak electrostatic attraction between one electronegative atom like O or N and a hydrogen atom covalently linked to a second electronegative atom. Hydrogen atoms can be donated by -NH (imidazole, indole, peptide); -OH (serine, threonine) and -NH2 (arginine, lysine). Hydrogen accepting groups are COO− (aspartic, glutamic) C=O (peptide); and S–S (disulphide).

ii. Electrostatic bonds (ionic bonds): Positive charges are donated by epsilon amino group of lysine, guanidinium group of arginine and imidazolium group of histidine. Negative charges are provided by beta and gamma carboxyl groups of aspartic and glutamic acids.

iii. Hydrophobic bonds are formed by interactions between nonpolar hydrophobic side chains by eliminating water molecules. This serves to hold lipophilic side chains together.

iv. The van der Waals forces are very weak, but collectively contribute maximum towards the stability of protein structure.
2-A. Alpha helix
Pauling (Nobel prize, 1954) and Corey described the alpha-helix and beta-pleated sheet structures of polypeptide chains in 1951.

i. **The alpha-helix is the most common and stable conformation** for a polypeptide chain. In proteins like hemoglobin and myoglobin, the alpha-helix is abundant, whereas it is virtually absent in chymotrypsin.

ii. The alpha helix is a **spiral structure** (Fig. 4.6). The polypeptide bonds form the back-bone and the side chains of amino acids extend outward.

iii. The structure is stabilized by hydrogen bonds between NH and C=O groups of the main chain.

iv. Each turn is formed by 3.6 residues. The distance between each amino acid residue (translation) is 1.5 Å.

v. The alpha-helix is generally **right handed**. Left handed alpha helix is rare, because amino acids found in proteins are of L-variety, which exclude left handedness. Proline and hydroxy proline will not allow the formation of alpha-helix.

2-B. Beta-pleated sheet

i. The polypeptide chains in beta-pleated sheet is almost fully extended. The distance between adjacent amino acids is 3.5Å.

ii. It is stabilized by hydrogen bonds between NH and C=O groups of neighboring polypeptide segments.

iii. Adjacent strands in a sheet can run in the same direction with regard to the amino and carboxy terminal ends of the polypeptide chain (parallel) or in opposite direction (anti parallel beta sheet) (Fig. 4.7). Beta-pleated sheet is the major structural motif in proteins like silk Fibroin (anti parallel), Flavodoxin (parallel) and Carbonic anhydrase (both).

iv. Beta bends may be formed in many proteins by the abrupt U-turn folding of the chain. Intrachain disulfide bridges stabilize these bends.

2-C. Collagen helix
It is a triple helical structure found in collagen (details in Chapter 52).

3. Tertiary Structure

i. Secondary structure denotes the configurational relationship between residues which are about 3-4 amino acids apart; or secondary level defines the organization at immediate vicinity of amino acids. The tertiary structure denotes three dimensional structure of the whole protein (Box 4.1 and Fig. 4.8). The tertiary structure defines the steric relationship of amino acids which are far apart from each other in the linear sequence, but are close in the three-dimensional aspect.

ii. The tertiary structure is maintained by **non-covalent** interactions such as hydrophobic bonds, electrostatic bonds and van der Waals forces. The tertiary structure acquired by native protein is always thermodynamically most stable.

iii. **Domain** is the term used to denote a compact globular functional unit of a protein. A domain is a relatively independent region of the protein, and may represent a functional unit. The domains are usually connected with relatively flexible areas of protein (see immunoglobulins, Chapter 49). Phenyl alanine hydroxylase enzyme contains 3 domains, one regulatory, one catalytic and one protein-protein interaction domains.

4. Quaternary Structure

i. Certain polypeptides will **aggregate to form one functional protein** (Box 4.1 and Fig. 4.8). This is referred to as the quaternary structure.

ii. The protein will lose its function when the subunits are dissociated.

---

**Fig. 4.8. Levels of organizations of proteins**
iii. The forces that keep the quaternary structure are hydrogen bonds, electrostatic bonds, hydrophobic bonds and van der Waals forces.

iv. Depending on the number of polypeptide chain, the protein may be termed as monomer (1 chain), dimer (2 chains), tetramer (4 chains) and so on. Each polypeptide chain is termed as subunit or monomer. Homodimer contains two copies of the same polypeptide chain. Heterodimer contains two different types of polypeptides as a functional unit.

v. For example, 2 alpha-chains and 2 beta-chains form the Hemoglobin molecule. Similarly, 2 heavy chains and 2 light chains form one molecule of Immunoglobulin G. Creatine kinase (CK) is a dimer. Lactate dehydrogenase (LDH) is a tetramer.

Structure-Function Relationship

The functions of proteins are maintained because of their ability to recognize and interact with a variety of molecules. The three dimensional structural conformation provides and maintains the functional characteristics. The three dimensional structure, in turn, is dependent on the primary structure. So, any difference in the primary structure may produce a protein which cannot serve its function. To illustrate the structure-function relationship, the following three proteins are considered; each belongs to a different class in the functional classification.

Enzymes: The first step in enzymatic catalysis is the binding of the enzyme to the substrate. This, in turn, depends on the structural conformation of the active site of the enzyme, which is precisely oriented for substrate binding (see Chapter 5). Carbonic anhydrase catalyses the reversible hydration of carbon dioxide. This enzyme makes it possible for the precise positioning of the CO₂ molecule and the hydroxyl (OH⁻) ion for the formation of bicarbonate ion. The zinc ion is located at a deep cleft coordinated to histidine residues. The CO₂ binding residues are very near to the zinc ion. Water binds to zinc ion, gets ionized to hydroxyl ion and it binds to the CO₂ which is proximally located. The substrates are brought in close proximity for the reaction to proceed.

Transport proteins: Hemoglobin, the transporter of oxygen is a tetrameric protein (alpha2, beta2), with each monomer having a heme unit (see Chapter 22). Binding of oxygen to one heme facilitates oxygen binding by other subunits. Binding of H⁺ and CO₂ promotes release of O₂ from hemoglobin. This allosteric interaction is physiologically important, and is termed as Bohr effect. Even a single amino acid substitution alters the structure and thereby the function. For example, in sickle cell anemia (HbS), the 6th amino acid in the beta chain is altered, leading to profound clinical manifestations.

Structural proteins: Collagen is the most abundant protein in mammals and is the main fibrous component of skin, bone, tendon, cartilage and teeth. Collagen forms a superhelical cable where the 3 polypeptide chains are wound around itself (Chapter 52). In collagen, every 3rd residue is glycine. The only amino acid that can fit into the triple stranded helix is glycine. The triple helix of collagen is stabilized by the steric repulsion of the rings of hydroxyproline and also by the hydrogen bonds between them. In vitamin C deficiency, failure of hydroxylation of proline/lysine leads to reduced hydrogen bonding and consequent weakness of collagen (Chapter 52). The quarter staggered triple helical structure of collagen is responsible for its tensile strength.

STUDY OF PROTEIN STRUCTURE

The first protein to be sequenced was insulin by Sanger in 1955 (Nobel prize in 1958). Before studying the structure, first a pure sample of the protein has to be available. The proteins are extracted and purified by various chromatography techniques (ion exchange, adsorption, partition, size exclusion, affinity, HPLC). The purity of the protein thus isolated is studied by electrophoresis (agar, PAGE, iso electric focussing). Further, molecular weight is determined by mass spectroscopy or by MALDI. Principles of all the above-said techniques are discussed in Chapter 54.

A. Steps for Determining the Primary Structure

1. Determination of the number of polypeptide chains in a protein. This is ascertained by treating them with Dansyl chloride, which combines with the N-terminal amino acid (Fig. 4.10). The tagged polypeptide chains are subjected to complete hydrolysis by boiling with 6 N HCl at 110°C for 18–36 hours under anaerobic conditions to give a mixture of amino acids. The number and nature of the dansyl amino acids can be determined and will indicate the number of polypeptide chains in the protein.
For example, if there are two different polypeptide chains in a protein, two different dansyl amino acids can be identified.

2. Determination of the amino acid composition by complete hydrolysis of the polypeptide chains, by chromatographic separation and quantitation.

3. Identification of N-terminal and C-terminal amino acids (Fig. 4.11).

4. Site specific hydrolysis of the polypeptide chain using specific enzymes to get a mixture of overlapping peptides.

5. Separation and purification of each of these peptides, and then analysing the amino acid sequence of each of the small peptides, and then deciphering the sequence of the whole protein.

1-B. End Group Analysis

i. The N-terminal amino acid has already been identified by treatment with dansyl chloride (Fig. 4.10). Originally Sanger used fluorodinitro benzene (FDNB, Sanger's reagent) for identification of N-terminal amino acid (Fig. 4.9).

ii. The C-terminal amino acid may be identified by Carboxypeptidase A and B.

These enzymes specifically hydrolyse and release the C-terminal amino acid from the polypeptide chain. Continued action of the enzyme would release amino acids sequentially from the C-terminal end. Carboxypeptidase A will not act if the C-terminal residue is Arginine, Proline or Lysine. Carboxypeptidase B will act only if the penultimate residue is proline.

1-C. Sequencing

The purified individual polypeptide chains are then sequenced using Edman's degradation technique. Edman's reagent is phenyl-isothiocyanate. It forms a covalent bond to the N-terminal amino acid of any peptide chain (Fig. 4.11). This can be identified. The Edman's reagent would then react with the second amino acid which now has the alpha amino group. The degradation is useful in sequencing first 10-30 amino acids.

1-D. Partial Hydrolysis

For very long chain proteins, the chain is broken into many small peptides of overlapping sequences. This is done by subjecting the polypeptide chain to hydrolysis by two or more different site specific enzymes. Each of these small peptides can be purified and subjected to Edman's degradation and sequenced.

Trypsin hydrolyses peptide bonds formed by alpha carboxyl group of Lysine and Arginine.

Chymotrypsin preferentially acts on peptide bonds formed by carboxyl group of amino acids Phe, Tyr, Trp, or Leu.

Cyanogen bromide (CNBr) attacks C-side of methionine residue and breaks the peptide bond.
**Box 4.3. Significance of Iso-electric pH (pI)**

1. The amino acid composition will determine the isoelectric pH (pI) of protein. The alpha amino group and carboxyl group are utilized for peptide bond formation, and hence are not ionisable. All other ionizable groups present in the protein will influence the pI of the protein.

2. At the iso-electric point, the number of anions and cations present on the protein molecule will be equal and the net charge is zero.

3. At the pI value, the proteins will not migrate in an electrical field. At the pI, solubility, buffering capacity and viscosity will be minimum; and precipitation will be maximum.

4. On the acidic side of pI, the proteins are cations and on alkaline side, they are anions in nature.

5. The pI of pepsin is 1.1; casein 4.6; human albumin 4.7; human insulin 5.4; human globulins 6.4; human hemoglobin 6.7; myoglobin 7; and lysozyme 11.

6. **Acidic dyes** such as eosin will dissociate into H⁺ + dye⁻, which will then attach with protein–NH₃⁺ (protein cations). **Basic dyes** such as hematoxylin and methylene blue are dissociated to OH⁻ + dye⁺, which will then stain Protein–COO⁻ (anions). Thus the staining characteristic of a protein is determined by the pI of that protein.

Each peptide is then analyzed and the whole sequence of the polypeptide is determined as if fitting in the parts of a jigsaw puzzle. The position of disulphide bonds can be determined by cleaving the native protein sample to get fragments with intact S–S bonds. These fragments are then identified.

**Finger Printing Method (Ingram's technique)**

This method was developed by Vernon Ingram in 1956. It helps to easily identify any qualitative abnormalities in protein structure. Here the protein is digested into many small peptides by trypsin. The mixtures of peptides are separated by chromatography (peptide mapping). The position of the peptide containing the altered amino acid is found to be different when compared with the peptide map of the normal polypeptide, e.g. beta chain of hemoglobin in HbA and HbS.

**Automated Sequencing**

Using the Edman’s degradation technique, sequencing can be completed within a few hours by automatic sequencers.

**Study of Higher Levels of Protein Structure**

The higher levels of protein structure may be studied by techniques using X-ray diffraction, ultraviolet light spectroscopy, optical rotatory dispersion, circular dichroism, nuclear magnetic resonance (NMR), etc.

NMR spectroscopy measures the absorbance of radio frequency of atomic nuclei. By studying the frequency at which a particular nucleus absorbs energy, we could get an idea of the functional group available in the molecule. Two dimensional NMR permits a three dimensional representation of the protein in solution. It also helps to study the alterations in conformation of a protein during binding with another ligand.

A beam of X-ray is diffracted by the electrons around each atom and the intensity of diffracted beam is detected by a photographic plate or collected by an electronic device. This **X-ray diffraction study** is possible only on crystallized proteins.

Nowadays, DNA sequencing is used to determine the amino acid sequence. In this method, at first, a rough sequencing of protein is done by Edman’s method. Based on this knowledge, small length oligonucleotide primers are made. These are used to amplify the appropriate gene by polymerase chain (PCR) reaction (See Chapter 55) and correct DNA clone is obtained. The sequence of that part of DNA is done. Using the knowledge of the genetic code (Chapter 41), the sequence of the encoded protein is identified.

**Chemical Synthesis of Peptides**

Peptides are artificially synthesized for the following purposes:

1. To check whether the sequence analysis is correct or not.
2. The primary structure of a peptide is altered by one or two amino acids, so as to determine the biologically important area or the active center.
3. To get pure preparations for medical or diagnostic purpose. For example, HIV antibody in the blood of AIDS patients is detected by ELISA method. For this, pure antigen from HIV is to be coated in the test tubes. Preparation of enough quantity of antigen from the virus is tedious and hazardous. The best way is to synthesize the antigenic part of the protein. Commercially it is cheaper to synthesize small peptides, than isolating them from biological sources.

Emil Fischer in 1890 developed the basic mechanism to protect or activate reactive groups of amino acids. Robert Merrifield in 1961 introduced the solid phase peptide synthesis (Nobel prize, 1984). He simplified the process by adding the carboxy terminal end amino acid to insoluble polystyrene beads, so that washing and purification processes become rapid. In principle, the carboxyl group of the last amino acid is fixed on the resin; and other amino acids are added sequentially. Insulin was the first major protein chemically synthesized. In 1964, Panayotis Katsoyannis in USA and Helmut Zahn from Germany, independently synthesized insulin.

**Physical Properties of Proteins**

1. Protein solutions exhibit colloidal properties and therefore scatter light and exert osmotic pressure. Osmotic pressure exerted by plasma proteins is clinically important (Chapter 28).

2. **Molecular weights** of some of the proteins are:
   - Insulin (5,700); Hemoglobin (68,000); Albumin (69,000); Immunoglobulins (1,50,000); Rabbit Papilloma Virus Protein (4,70,00,00).

3. **Shape** of the proteins also vary. Thus, Insulin is globular, Albumin is oval in shape, while...
Chapter 4; Proteins: Structure and Function

Fibrinogen molecule is elongated. Bigger and elongated molecules will increase the viscosity of the solution.

4. **Iso-electric pH** of amino acids has been described in Chapter 3. Since proteins are made of amino acids, the pI of all the constituent amino acids will influence the pI of the protein. Application of pI is shown in Box 4.3.

### Precipitation Reactions of Proteins

Purification of enzymes and other proteins usually start with precipitating them from solution. The stability of proteins in solution will depend mainly on the charge and hydration. Polar groups of the proteins (-NH₂, COOH, OH groups) tend to attract water molecules around them to produce a shell of hydration. Any factor which neutralises the charge or removes water of hydration will therefore cause precipitation of proteins. The following procedures are used for protein precipitation:

1. **Salting Out**

   When a neutral salt such as ammonium sulphate or sodium sulphate is added to protein solution, the shell of hydration is removed and the protein is precipitated. This is called salting out. As a general rule, higher the molecular weight of a protein, the salt required for precipitation is lesser. Thus globulins are precipitated with half saturation of ammonium sulphate; but albumin will need full saturation with ammonium sulphate for complete precipitation.

2. **Iso-electric Precipitation**

   Proteins are least soluble at their iso-electric pH. Some proteins are precipitated immediately when adjusted to their iso-electric pH. The best example is **Casein** which forms a flocculent precipitate. When heated at iso-electric point, some proteins will denature irreversibly to produce thick floating conglomereats called coagulum. This process is called heat coagulation. **Albumin** is easily coagulated, and globulins to a lesser extent. (See Fig. 4.13). This is the basis of the **Heat and Acetic Acid test**, very commonly employed to detect the presence of albumin in urine (See Chapter 27).

---

**Fig. 4.12. Denaturation of protein**

Fibrinogen molecule is elongated. Bigger and elongated molecules will increase the viscosity of the solution.

**Box 4.4. Denaturation of Proteins**

1. Mild heating, treating with urea, salicylate, X-ray, ultraviolet rays, high pressure, vigorous shaking and similar physico-chemical agents produce denaturation.
2. There will be non-specific alterations in secondary, tertiary and quaternary structures of protein molecules. **Primary structure is not altered** during denaturation (Fig. 4.12).
3. In general, during the process the solubility is decreased while precipitability of the protein is increased. It often causes **loss of biological activity**.
4. Native proteins are often resistant to proteolytic enzymes, but denatured proteins will have more exposed sites for enzyme action. Since cooking leads to denaturation of proteins, cooked foods are more easily digested.
5. Denatured proteins are sometimes re-natured when the physical agent is removed. Ribonuclease is a good example for such **reversible denaturation**. Immunoglobulin chains are dissociated when treated with urea. When the urea is removed by dialysis, the subunits are reassociated and biological activity of immunoglobulin is regained.
6. But many proteins undergo irreversible denaturation. For example, albumin once heated, cannot be renatured by cooling.

**Box 4.5. Significance of Heat Coagulation**

When heated at iso-electric point, some proteins will denature irreversibly to produce thick floating conglomerates called coagulum. This process is called heat coagulation. **Albumin** is easily coagulated, and globulins to a lesser extent. (See Fig. 4.13). This is the basis of the **Heat and Acetic Acid test**, very commonly employed to detect the presence of albumin in urine (See Chapter 27).
precipitate at pH 4.6 and redissolves in highly acidic or alkaline solutions. When milk is curdled, the casein forms the white curd, because lactic acid produced by the fermentation process lowers the pH to the iso-electric point of casein.

3. Precipitation by Organic Solvents
When an organic solvent is added to the protein solution, water molecules available for proteins are reduced, and precipitation occurs. Organic solvents reduce the dielectric constant of the medium which also favors protein precipitation. Hence, alcohol is a powerful protein precipitating agent. This may explain the disinfectant effect of alcohol.

4. Precipitation by Heavy Metal Ions
In alkaline medium, proteins have net negative charge, or are anions. To such a solution, if salts of heavy metals are added, positively charged metal ions can complex with protein molecules and metal proteinates are precipitated. Salts of Copper, Zinc, Lead, Cadmium and Mercury are toxic, because they tend to precipitate normal proteins of the gastro-intestinal wall. Based on this principle, raw egg is sometimes used as an antidote for mercury poisoning.

5. Precipitation by Alkaloidal Reagents
Tungstic acid, Phosphotungstic acid, Trichloro acetic acid, Picric acid, Sulphosalicylic acid and Tannic acid are powerful protein precipitating agents. These acids lower the pH of medium, when proteins carry net positive charges. These protein cations are complexed with negatively charged ions to form protein-tungstase, protein-picare, etc. and thick flocculent precipitate is formed. In clinical laboratory phospho-tungstic or trichloro acetic acid are usually used for precipitating proteins. Tanning in leather processing is based on the protein precipitating effect of tannic acid. Under certain conditions, proteins undergo denaturation, which is a mild form of precipitation reaction (Box 4.4). Heat coagulation is an irreversible precipitation process (Box 4.5 and Fig. 4.3).

A. Classification based on functions
1. Catalytic proteins, e.g. enzymes
2. Structural proteins, e.g. collagen, elastin
3. Contractile proteins, e.g. myosin, actin.
4. Transport proteins, e.g. hemoglobin, myoglobin, albumin, transferrin
5. Regulatory proteins or hormones, e.g. ACTH, insulin, growth hormone
6. Genetic proteins, e.g. histones
7. Protective proteins, e.g. immunoglobulins, interferons, clotting factors.

B. Classification based on Composition and Solubility

B-1. Simple Proteins
According to definition, they contain only amino acids.

i. Albumins: They are soluble in water and coagulated by heat. Human serum albumin has a molecular weight of 69,000. Other examples are lactalbumin of milk and egg albumin.

ii. Globulins: These are insoluble in pure water, but soluble in dilute salt solutions. They are also coagulated by heat. Examples are egg globulin, serum globulins, legumin of peas.

iii. Protamines: These are soluble in water, dilute acids and alkalies. They are not coagulated by heating. They contain large number of arginine and lysine residues, and so are strongly basic. Hence, they can combine with other acidic proteins. Protamine zinc insulinate is a common commercial preparation of insulin.

iv. Prolamines: They are soluble in 70-80% alcohol, but insoluble in pure water. They are rich in proline but lack in lysine. Examples are zein from corn, gliadin of wheat, hordein of barley.

v. Lectins: Lectins are precipitated by 30–60% ammonium sulphate. They are proteins

CLASSIFICATION OF PROTEINS
It is almost impossible to correctly classify all proteins. The following classifications are given only to introduce a broader idea to the students.
having high affinity to sugar groups. Lectin from *Dolichos biflorus* will agglutinate human blood group A1 RBCs. Phytohemagglutinin (PHA), a lectin from *Phaseolus vulgaris* (red kidney bean) agglutinates all RBCs and WBCs. Concanavalin-A (ConA) from legumes will specifically attach to mannose and glucose.

**vi. Scleroproteins:** They are insoluble in water, salt solutions and organic solvents and soluble only in **hot strong acids**. They form supporting tissues. Examples are collagen of bone, cartilage and tendon; keratin of hair, horn, nail and hoof.

**B-2. Conjugated Proteins**

They are combinations of protein with a non-protein part, called **prosthetic group** (*Table 4.1*). Conjugated proteins may be classified as follows:

i. **Glycoproteins:** These are proteins combined with carbohydrates. Hydroxyl groups of serine or threonine and amide groups of asparagine and glutamine form linkages with carbohydrate residues. **Blood group antigens** and many serum proteins are glycoproteins. When the carbohydrate content is more than 10% of the molecule, the viscosity is correspondingly increased; they are sometimes known as **mucoproteins** or proteoglycans.

ii. **Lipoproteins:** These are proteins loosely combined with lipid components. They occur in blood and on cell membranes. Serum lipoproteins are described in Chapter 12.

iii. **Nucleoproteins:** These are proteins attached to nucleic acids, e.g. Histones. The DNA carries negative charges, which combines with positively charged proteins.

iv. **Chromoproteins:** These are proteins with colored prosthetic groups. Hemoglobin (Heme, red); Flavoproteins (Riboflavin, yellow), Visual purple (Vitamin A, purple) are some examples of chromoproteins.

v. **Phosphoproteins:** These contain phosphorus. **Casein** of milk and **vitellin** of egg yolk are examples. The phosphoric acid is esterified to the hydroxyl groups of serine and threonine residues of proteins.

vi. **Metalloproteins:** They contain metal ions. Examples are Hemoglobin (Iron), Cytochrome (Iron), Tyrosinase (Copper) and Carbonic anhydrase (Zinc).

**B-3. Derived Proteins**

They are degradation products of native proteins. Progressive hydrolysis of protein results in smaller and smaller chains: Protein → peptones → peptides → amino acids.

**C. Classification Based on the Shape**

**C-1. Globular Proteins**

They are spherical or oval in shape. They are easily soluble. Examples are albumins, globulins and protamines.

**C-2. Fibrous Proteins**

The molecules are elongated or needle shaped. Their solubility is minimum. They resist digestion. Collagen, elastin and keratins are examples.

**D. Classification Based on Nutritional Value**

**D-1. Nutritionally Rich Proteins**

They are also called as **complete proteins** or **first class proteins**. They contain all the essential amino acids in the required proportion. On supplying these proteins in the diet, children will grow satisfactorily. A good example is **casein** of milk.

**D-2. Incomplete Proteins**

They lack one essential amino acid. They cannot promote body growth in children; but may be able to sustain the body weight in adults. Proteins from **pulses** are deficient in **methionine**, while proteins of **cereals** lack in **lysine**. If both of them are combined in the diet, adequate growth may be obtained. (See mutual supplementation, Chapter 36).

**D-3. Poor Proteins**

They lack in many essential amino acids and a diet based on these proteins will not even sustain the original body weight. Zein from corn lacks tryptophan and lysine.

**Biologically Important Peptides**

When 10 or less number of amino acids are joined together, it is called an oligopeptide. Some of them are biologically active. A few examples are given below:

i. **Thyrotropin releasing hormone** (TRH) is a tripeptide with the sequence of Glu-His-Pro; but the Glu is modified to form pyroglutamic acid.
ii. **Glutathione** is a tripeptide. It is gamma glutamyl cysteinyl glycine (See Fig.15.19). It is involved in erythrocyte membrane integrity and is important in keeping enzymes in active state.

iii. **Oxytocin and Vasopressin** (ADH) are nanopeptides; with 9 amino acids. They are secreted by posterior pituitary.

iv. **Angiotensin I** has 10 amino acids and Angiotensin II has 8 amino acids. They cause hypertension (Chapter 30)

v. **Gramicidin S**, an antibiotic produced by *Bacillus brevis*, contains 10 amino acids. It is circular and contains D-phenyl alanine (usual proteins contain only L-amino acids).

Polypeptide hormones (more than 10 amino acids) are described in Chapters 24 and 45.

### QUANTITATIVE ESTIMATION

#### 1. Kjeldahl’s Procedure

i. The protein sample is digested by boiling (360°C) with concentrated sulphuric acid in presence of copper sulphate and sodium sulphate as catalysts.

ii. The nitrogen present in the protein is reduced to ammonia which is absorbed by acid medium to become ammonium sulphate. After cooling, the digest is made alkaline by adding excess alkali. Now ammonia (NH₃) is liberated, which is absorbed by a known quantity of standard acid kept in a vessel. The excess acid present in the vessel is back-titrated with a standard base, from which the liberated ammonia can be calculated.

iii. Then the quantity of nitrogen originally present in the protein is assessed. Since **proteins**, on an average contain \(16\% \) nitrogen, the weight of nitrogen x 100/16, or nitrogen x 6.25 will give the value of proteins present in the original sample.

iv. **Advantage**: This is the most accurate and precise method. It is generally used for standardising a particular protein; that protein is then used for calibrating other proteins employing other easier methods.

v. **Disadvantage**: It takes many days to get the result, and is unsuitable for routine clinical work.

#### 2. Biuret Method

i. Cupric ions chelate with peptide bonds of proteins in alkaline medium to produce a pink or violet color. The intensity of the color is proportional to the number of peptide bonds. The color is then compared with a standard protein solution treated with the biuret reagent, and estimated colorimetrically. The principle of colorimetry is discussed in Chapter 54.

ii. **Advantage**: The biuret method is a simple one step process, and is the most widely used method for plasma protein estimations.

iii. **Disadvantage**: The sensitivity of the method is less and is unsuitable for estimation of proteins in milligram or microgram quantities.

#### 3. Lowry’s Method

i. This is based on the reduction of Folin-Ciocalteau phenol reagent (phosphomolybdic acid and phosphotungstic acid) by the tyrosine and tryptophan residues of protein. A blue color is developed which is compared with that produced by a known standard.

ii. **Advantage**: This method is very sensitive and protein content in microgram range can be measured. If the tyrosine and tryptophan content of the proteins of test and standard vary widely, then the accuracy is lost; this is a minor disadvantage of this method.

OH Lowry published the paper on protein estimation in 1951. This is the most cited article in the scientific literature.
4. Spectrophotometric Estimation
   i. Proteins will absorb ultraviolet light at 280 nm. This is due to the tyrosine and tryptophan residues in the protein. Quantitation is done by comparing the absorbance of the test solution with a known standard.
   ii. **Advantage and disadvantage:** The method is accurate, simple and highly sensitive up to microgram quantities. Since color reaction using other chemicals is not employed, the protein is not wasted in this method. However, the instrument is costly. Please see discussion in Chapter 54.

5. Radial Immuno Diffusion (Mancini's technique)
   Please note that the name is "radial" and not "radio". There is no radiation applied in this process. As the precipitation arc is moving radially outward from the point of application, the name "radial" is given. Here specific antiserum is incorporated in the liquid agar, and then allowed to solidify on a glass plate. Then small wells (1 mm dia) are cut in the agar, and antigen (protein solution, patient’s sera, etc.) is added in the well. The plate is incubated at 4°C for 1 to 3 days. The antigen molecules diffuse radially around the wells and react with the specific antibody molecules present all over the agar. A white ring of precipitate is seen, where equimolecular concentration (1:1 ratio) of antigen and antibody is attained. The **diameter of the precipitation ring will be proportional to the log of antigen concentration**. If known standards of different concentration is included along with the test, a standard graph is plotted, from which quantity of test substance can be obtained (Fig. 4.14).
   **Advantage:** The procedure is simple and sensitive enough to quantify mg or microgram quantities of proteins. Since the method is based on antibodies, the test is exquisitely specific. Serum levels of immunoglobulins, complement components, etc. are routinely assayed by this method.

6. Nephelometry
   It is based on the measurement of scattering of light by colloids, originally studied by Richard Zsigmondy (Nobel prize, 1925). Scattering of light by antigen-antibody complexes was used as a quantitation method by Libby in 1938. Nephelometry is defined as the **detection of light scattered by turbid particles in solution**. If albumin is to be estimated, specific antibody against albumin is added. The resultant antigen-antibody complex will form turbidity of the solution. A beam of light (preferably laser beam) is passed through the solution. The particles in the solution will scatter light. The light turning at 30° to 90° angle (generally 60°) is collected and passed into a detector system. The emergent scattered light will be proportional to the turbidity of the solution, which in turn will be proportional to the antigen.
   **Advantage and disadvantage:** This is a very rapid method and suitable for automated programs. Microgram quantities can be accurately estimated. The instrument and reagents are costly and needs careful standardization.

7. Turbidimetry
   Proteins in biological fluids like urine and CSF can be estimated by adding protein precipitating agents (sulphosalicylic acid or specific antibody); the turbidity thus produced is measured. The method is simple, but less accurate. Nephelometry and turbidimetry are based on the same principle of scattering of light by colloidal particles. In nephelometry, emergent light scattered at 60° angle is observed; while in turbidimetry, light emerging at 180° angle is detected. Turbidimetry is comparatively cheaper. Newer techniques are based on immunoturbidimetry.

8. RIA and ELISA Tests
   If proteins of nanogram and picogram quantities are to be estimated, radioimmunoassay (RIA) or enzyme linked immuno sorbent assay (ELISA) techniques are to be employed. These are described in detail in Chapter 54.

**Proteomics**

Proteomics is the study of the entire galaxy of proteins produced by a cell under different conditions. At a particular time, a gene is "on" in a particular cell; but it will be "off" in another cell. Expression of proteins during growth and development will be different from the resting cell. Proteins produced by a gastrointestinal cell and a neuronal cell will be entirely different. Many proteins are getting post-translational modification, that too, at different levels at various organs. But genes are the same in all cells at all times. Therefore, study of genes (genomics) will give only a partial picture of what is going on in nature. Human body contains hundreds of different cells, which express thousands of proteins, at different times and under the influence of different stimuli. Proteomics attempt to study all these multifaceted picture in toto.
Once upon a time there was a rich merchant. In his last will and testament, he put aside his 17 white horses to his 3 sons to be shared thus; 1/2 for the 1st son, 1/3 for the 2nd son and 1/9 for the 3rd son. After his death, the sons started to quarrel, as the division could not produce whole number. Then their brother-in-law told them that they should include his black horse also for the sharing purpose. Thus now they had 17 + 1 = 18 horses, and so division was possible; 1st son got one-half or 9 horses; 2nd son got 6 and 3rd son 2 horses. Now all the 17 white horses were correctly divided among the sons. The remaining black horse was taken back by the brother-in-law. Catalysts are similar to this black horse.

The reaction, although theoretically probable, becomes practically possible only with the help of catalysts. They enter into the reaction, but come out of the reaction without any change. Catalysts are substances which accelerate the rate of chemical reactions, but do not change the equilibrium.

Berzelius in 1835 showed hydrolysis of starch by malt extract and put forward the theory of enzyme catalysis (see Table 1.1). In 1878 Willy Kunhe coined the word enzyme, which in Greek means "in yeast". Edward Buchner (Nobel prize 1907) showed that cell-free extract of yeast could catalyse the fermentation of sucrose to ethanol. He named this active principle as Zymase. Sir Arthur Harden in 1897 (Nobel prize 1929) showed that Zymase is a complex mixture of enzymes, each catalysing a separate step in the degradation of sucrose. The rate of chemical reactions, chemical equilibrium and catalysis were studied by Ostwald (Nobel prize 1909). In 1926, James Sumner (Nobel prize 1946) was the first to crystallise the enzyme urease. In 1930, John Northrop (Nobel prize, 1946) crystallized a number of proteolytic enzymes from gastrointestinal tract and proved that they are all proteins.

Enzymes are biocatalysts
Life is possible due to the co-ordination of numerous metabolic reactions inside the cells. Proteins can be hydrolyzed with hydrochloric acid by boiling for a very long time; but inside the body, with the help of enzymes, proteolysis takes place within a short time at body temperature. Enzyme catalysis is very rapid; usually 1 molecule of an enzyme can act upon about 1000 molecules of the substrate per minute. Lack of enzymes will lead to block in metabolic pathways causing inborn errors of metabolism.

The substance upon which an enzyme acts, is called the substrate. The enzyme will convert the substrate into the product or products.

Characteristics of Enzymes
i. Almost all enzymes are proteins. Enzymes follow the physical and chemical reactions of proteins.
ii. They are heat labile.
iii. They are water-soluble.
iv. They can be precipitated by protein precipitating reagents (ammonium sulfate or trichloroacetic acid).
v. They contain 16% weight as nitrogen.

CLASSIFICATION OF ENZYMES
When early workers isolated certain enzymes, whimsical names were given. Some of these, such

as Pepsin, Trypsin, Chymotrypsin, etc. are still used. Later, it was agreed to call the enzymes by adding the suffix “-ase” to the substrate. Thus, enzyme Lactase acts on the substrate lactose, and the products glucose and galactose are formed. Enzymes that hydrolyse starch (amylose) are termed as amylases; those that dehydrogenate the substrates are called dehydrogenases. These are known as the trivial names of the enzymes.

IUBMB System of Classification
International Union of Biochemistry and Molecular Biology (IUBMB) in 1964, (modified in 1972 and 1978), suggested the IUBMB system of nomenclature of enzymes. It is complex and cumbersome; but unambiguous. As per this system, the name starts with EC (enzyme class) followed by 4 digits. First digit represents the class, Second digit stands for the subclass, Third digit is the sub-subclass or subgroup, Fourth digit gives the number of the particular enzyme in the list. The enzymes are grouped into following six major classes (Box 5.1).

- **Class 1: Oxidoreductases**
  This group of enzymes will catalyse oxidation of one substrate with simultaneous reduction of another substrate or co-enzyme. This may be represented as
  \[ \text{AH}_2 + \text{B} \rightarrow \text{A} + \text{BH}_2 \]
  for example,
  \[ \text{Alcohol} + \text{NAD}^+ \rightarrow \text{Aldehyde} + \text{NADH} + \text{H}^+ \]
  The enzyme is **Alcohol dehydrogenase**; IUB name is Alcohol-NAD-oxidoreductase; Code number is EC.1.1.1.1. Oxidoreductases may also oxidise substrates by adding oxygen, e.g. oxidases, oxygenases and dehydrogenases (Chapter 19).

- **Class 2: Transferases**
  This class of enzymes transfers one group (other than hydrogen) from the substrate to another substrate. This may be represented as
  \[ \text{A-R} + \text{B} \rightarrow \text{A} + \text{B-R} \]
  For example,
  \[ \text{Hexose} + \text{ATP} \rightarrow \text{Hexose-6-phosphate} + \text{ADP} \]
  The name of enzyme is **Hexokinase** and systematic name is ATP-Hexose--6-phosphate-transferase.

- **Class 3: Hydrolases**
  This class of enzymes can hydrolyse ester, ether, peptide or glycosidic bonds by adding water and then breaking the bond.
  \[ \text{Acetyl choline} + \text{H}_2\text{O} \rightarrow \text{Choline} + \text{acetate} \]
  The enzyme is **Acetyl choline esterase** or **Acetyl choline hydrolase** (systematic). All digestive enzymes are hydrolases.

- **Class 4: Lyases**
  These enzymes can remove groups from substrates or break bonds by mechanisms other than hydrolysis. For example,
  \[ \text{Fructose-1,6-bisphosphate} \rightarrow \text{Glyceraldehyde-3-phosphate} + \text{dihydroxy acetone phosphate} \]

Box 5.1. Classification of Enzymes

**Class 1. Oxidoreductases**: Transfer of hydrogen or addition of oxygen; e.g. Lactate dehydrogenase (NAD); Glucose-6-phosphate dehydrogenase (NADP); Succinate dehydrogenase (FAD); di-oxygenases.

**Class 2. Transferases**: Transfer of groups other than hydrogen. Example, Aminotransferase. (Subclass: Kinase, transfer of phosphoryl group from ATP; e.g. Hexokinase)

**Class 3. Hydrolases**: Cleave bond and add water; e.g. Acetyl choline esterase; Trypsin

**Class 4. Lyases**: Cleave without adding water; e.g. Aldolase; HMG CoA lyase; ATP Citrate lyase. (Subclass: Hydratase;add water to a double bond)

**Class 5. Isomerases**: Intramolecular transfers. They include racemases and epimerases. Example, Triose phosphate isomerase.

**Class 6. Ligases**: ATP dependent condensation of two molecules, e.g. Acetyl CoA carboxylase; Glutamine synthetase; PRPP synthetase

Box 5.2. Synthetase and Synthase are Different

**Synthetases** are ATP-dependent enzymes catalysing biosynthetic reactions; they belong to Ligases (class 6). Examples are Carbamoyl phosphate synthetase; Arginino succinate synthetase; PRPP synthetase and Glutamine synthetase

**Synthases** are enzymes catalysing biosynthetic reactions; but they do not require ATP directly; they belong to classes other than Ligases. Examples are Glycogen synthase and ALA synthase
**Class 5: Isomerases**

These enzymes can produce optical, geometric or positional isomers of substrates. Racemases, epimerases, cis-trans isomerases are examples.

Glyceraldehyde-3-phosphate $\longrightarrow$ Di-hydroxy-acetone-phosphate

Enzyme is Triose phosphate isomerase.

**Class 6: Ligases**

These enzymes link two substrates together, usually with the simultaneous hydrolysis of ATP, (Latin, Ligare = to bind). For example,

Acetyl CoA + CO2 + ATP $\rightarrow$ Malonyl CoA + ADP + Pi

Enzyme is Acetyl CoA carboxylase.

A summary of classification is given in Box 5.1. The differences between synthetase and synthase are shown in Box 5.2.

---

**CO-ENZYMES**

i. Enzymes may be simple proteins, or complex enzymes, containing a non-protein part, called the **prosthetic group**. The prosthetic group is called the **co-enzyme**. It is heat stable. Salient features of co-enzymes are shown in Box 5.3.

ii. The protein part of the enzyme is then named the **apo-enzyme**. It is heat labile.

iii. These two portions combined together is called the **holo-enzyme**.

iv. Co-enzymes may be divided into **two groups**

   v-a. Those taking part in reactions catalyzed by oxidoreductases by donating or accepting hydrogen atoms or electrons.

   v-b. Those co-enzymes taking part in reactions transferring groups other than hydrogen.

---

**First Group of Co-enzymes**

In the first group, the change occurring in the substrate is counter-balanced by the co-enzymes. Therefore, such co-enzymes may be considered as **co-substrates** or secondary substrates. In the example shown in Fig. 5.1, the substrate lactate is oxidized, and simultaneously the co-enzyme (co-substrate) is reduced. If the reaction is reversed, the opposite effect will take place.

Other such examples are NADP–NADPH; FAD–FADH2 and FMN–FMNH2.

**Nicotinamide Adenine Dinucleotide (NAD+)**

i. This is a co-enzyme synthesized from Nicotinamide, a member of vitamin B complex. The structure of NAD+ is Nicotinamide-Ribose-P-P-Ribose-Adenine (Fig. 34.6). Warburg (Nobel prize, 1931) elucidated the structure of NAD+.

---

**Fig. 5.1.** One co-enzyme molecule can work with different enzymes.
Adenosine Triphosphate (ATP)

i. ATP is considered to be the energy currency in the body. Fiske and Subba Row first isolated ATP in 1926 and Lohmann in 1929 showed the importance of ATP in muscle contraction.

ii. In the ATP molecule, the second and third phosphate bonds are ‘high energy’ bonds (as shown with squiggle bonds in Fig. 5.3).

iii. During the oxidation of food stuffs, energy is released, a part of which is stored as chemical energy in the form of ATP.

iv. The endergonic reactions are carried out with the help of energy released from hydrolysis of ATP.

Second Group of Co-enzymes

These co-enzymes take part in reactions transferring groups other than hydrogen. A particular group or radical is transferred from the substrate to another substrate. Most of them belong to vitamin B complex group. A few such examples are given in Table 5.1.

Metallo-enzymes

i. These are enzymes which require certain metal ions for their activity. Some examples are given in Table 5.2.

ii. In certain cases, e.g. copper in Tyrosinase, the metal is tightly bound with the enzyme.

iii. In other cases, even without the metal ion, enzyme may be active; but when the metal ion is added, the activity is enhanced. They are called ion-activated enzymes, e.g. calcium ions will activate pancreatic lipase.

Co-factors

The term co-factor is used as a collective term to include co-enzymes and metal ions. Co-enzyme is an organic co-factor.
iv. During enzyme substrate binding, weak interactions between enzyme and substrate are optimized. This weak binding interaction between enzyme and substrate provides the major driving force for the enzymatic catalysis.

v. Enzymes reduce the magnitude of this activation energy. This can be compared to making a tunnel in a mountain, so that the barrier could be lowered (Fig. 5.4). For example, activation energy for acid hydrolysis of sucrose is 26,000 cal/mol, while the activation energy is only 9,000 cal/mol when hydrolyzed by sucrase.

2. Acid Base Catalysis

Protonated form of histidine is an example of a general acid and its conjugate base, the general base (Fig. 5.5). The action of ribonuclease is an example of acid-base catalysis. Histidine residues 12 and 119 at the active site of ribonuclease function as acid and base in catalysis. Histidine 12 acts as an acid and donates a proton to form the basic form. Then the 2'-3' cyclic phosphate is formed. Histidine 112 accepts a proton from the cyclic phosphate and product is released.

In the enzymes of aspartyl protease family, catalysis involves two aspartyl residues, which act as acid-base catalysts. Catalysis by pepsin, cathepsin and protease of HIV (human immunodeficiency virus) belong to this group of enzymes.

3-A. Substrate Strain

Binding of substrate to a preformed site on the enzyme can induce strain in the substrate. The energy level of the substrate is raised. A combination of substrate strain and acid base catalysis is seen in the action of lysozyme.

The lysozyme substrate has a repeating hexasaccharide unit. Binding of the substrate to the enzyme generates a strained conformation in the enzyme substrate complex (D in Fig. 5.6). In the transition state, acid catalyzed hydrolysis of the glycosidic linkage by a glutamic acid residue at the active site generates a carbonium ion on the D residue. This relieves the strain generated in the initial enzyme-substrate complex. This results in the change from transition state to products. The glycosidic bond between N-acetyl glucosamine and N-acetyl muramic acid on the bacterial cell wall is thus hydrolyzed. This accounts for bactericidal action of lysozyme. Lysozyme was purified and studied by Howard Florey (Nobel prize, 1945).

3-B. Serine proteases

They are enzymes with a serine residue at the active site and most of the proteolytic enzymes belong to this group, e.g. trypsin, chymotrypsin, clotting factors (Table 5.3).
3-C. Action of chymotrypsin
It is a combination of covalent and acid base catalysis. The peptide bond is hydrolyzed through acid catalyzed nucleophilic attack, utilising the serine 195 residue of the enzyme. The enzyme substrate complex is formed by the binding of the aromatic amino acid residue with the hydrophilic pocket on the active site on the enzyme. A covalent acyl enzyme intermediate is formed. Cleavage of the peptide bond occurs. Serine 195, Histidine 57 and Aspartate 102 are the catalytic groups.

4. Covalent catalysis
In covalent catalysis, a nucleophilic (negatively charged) or electrophilic (positively charged) group of the enzyme attacks the substrate. This results in covalent binding of the substrate to the enzyme. Similarly, co-enzymes often form covalent bonds with the substrates.

5. Entropy effect
Enzymes enhance reaction rates by decreasing entropy. When correctly positioned and bound on the enzyme surface, the substrates are strained to the transition state. This is referred to as the proximity effect. Chemical reactions need physical apposition of two reactants. The occurrence of collision between two substrate molecules is determined by statistical probability. Since substrates usually are present in low concentrations, the collision probability is less and hence the reaction velocity is low. But a complex formation between the enzyme and the two substrate molecules can improve the collision probabilities many fold, causing the rapid rate of reaction.

6. Product Substrate Orientation Theory
Enzyme has appropriate three dimensional structure to keep the substrates in a specific orientation, such that the reactive groups come in to physical apposition, leading to speedy reactions (Fig. 5.8). It has been shown that the hydroxyl group of the 6th carbon atom of glucose and the terminal phosphate group of ATP are juxtaposed with the help of hexokinase.

MICHAELIS–MENTEN THEORY
i. In 1913, Michaelis and Menten put forward the Enzyme–Substrate complex theory. Accordingly, the enzyme (E) combines with the substrate (S), to form an enzyme-substrate (ES) complex, which immediately breaks down to the enzyme and the product (P) (Fig. 5.7).
\[
E + S \rightleftharpoons E–S \text{ Complex} \rightarrow E + P
\]
ii. Alkaline phosphatase hydrolyses a number of phosphate esters including glucose-6-

![Fig. 5.5. Acid base catalysis with the help of histidine](image)

![Fig. 5.6. Active center of Lysozyme. A,B,C,D,E,F are carbohydrate units (substrate). D = N-acetyl muramic acid; E=N-acetyl glucosamine. Bond is broken between D and E, with the help of Glu and Asp residues in the enzyme, which are opposite to each other](image)

![Fig. 5.7. Enzyme substrate complex](image)

![Fig. 5.8. Correct alignment of amino acids in the active center of the enzyme](image)
phosphate. The active center of this enzyme contains a serine residue, and the reaction is taking place in the following two steps:

a. $E$-Serine-OH+Glucose-6-P→
   $E$-Serine-O-P+Glucose

b. $E$-Serine-O-P→
   $E$-Serine-OH+Pi

Thus the overall reaction is

Glucose-6-P→Glucose + Pi

In this reaction mixture, the enzyme substrate complex, $E$-Serine-O-P, has been isolated.

**FISCHER’S TEMPLATE THEORY**

i. It states that the three dimensional structure of the active site of the enzyme is complementary to the substrate.

ii. Thus enzyme and substrate fit each other. Substrate fits on the enzyme, similar to lock and key. The lock can be opened by its own key only (Figs 5.9 and 5.10).

iii. However, Fischer envisaged a rigid structure for enzymes, which could not explain the flexibility shown by enzymes.

**KOSHLAND'S INDUCED FIT THEORY**

i. Conformational changes are occurring at the active site of enzymes concomitant with the combination of enzyme with the substrate. At first, substrate binds to a specific part of the enzyme.

ii. This leads to more secondary binding and conformational changes. The substrate induces conformational changes in the enzyme, such that precise orientation of catalytic groups is effected (Fig. 5.8). A simplified explanation is that a glove is put on a hand. At first, the glove is in a partially folded position, but hand can enter into it. When the hand is introduced, the glove is further opened. Similarly, conformational changes occur in the enzyme when the substrate is fixed.

iii. When substrate analog is fixed to the enzyme, some structural alteration may occur; but reaction does not take place due to lack of proper alignment (Fig. 5.8). Allosteric regulation can also be explained by the hypothesis of Koshland.

**ACTIVE SITE OR ACTIVE CENTER OF ENZYME**

Catalysis occurs at the active center or active site. Salient features are shown in Box 5.4. See Tables 5.3, 5.4 and Fig. 5.8 also.
Active Site of Ribonuclease

The catalytic site of ribonuclease also lies within a hydrophobic cleft, where 7th Lysine and 41st Lysine lie on one side and 12th Histidine and 119th Histidine on the opposite side of the binding site for uridylic acid. These active groups are brought to the specific orientation by the tertiary structure of the protein. The amino acid sequence and active conformation of ribonuclease were studied by Christian Anfinsen, Stanford Moore and William Stein, all three were awarded Nobel prize in 1972. Proteolytic enzymes having a serine residue at the active center are called serine proteases, e.g. pancreatic proteases (Table 5.3), and coagulation factors. Other examples are given in Table 5.4.

THERMODYNAMIC CONSIDERATIONS

From the standpoint of energy, the enzymatic reactions are divided into 3 types:

1. Exergonic or Exothermic Reaction
   Here energy is released from the reaction, and therefore reaction essentially goes to completion, e.g. urease enzyme:
   \[ \text{Urea} \rightarrow \text{ammonia + CO}_2 + \text{energy} \]
   At equilibrium of this reaction, the substrate will be only 0.5% and product will be 99.5%. Such reactions are generally irreversible.

2.Isothermic Reaction
   When energy exchange is negligible, and the reaction is easily reversible, e.g.
   \[ \text{Pyruvate} + 2\text{H} \rightarrow \text{Lactate} \]

3. Endergonic or endothermic
   Energy is consumed and external energy is to be supplied for these reactions. In the body this is usually accomplished by coupling the endergonic reaction with an exergonic reaction, e.g. Hexokinase catalyses the following reaction:
   \[ \text{Glucose} + \text{ATP} \rightarrow \text{Glucose-6-phosphate} + \text{ADP} \]

ENZYME KINETICS

Velocity or rate of enzyme reaction is assessed by the rate of change of substrate to product per unit time. In practice, initial velocity is

by coupling the endergonic reaction with an exergonic reaction, e.g. Hexokinase catalyses the following reaction:

Glucose + ATP → Glucose-6-phosphate + ADP

Box 5.4. Active Center of Enzyme

1. The region of the enzyme where substrate binding and catalysis occurs is referred to as active site or active center (Tables 5.3 and 5.4).
2. Although all parts are required for keeping the exact three dimensional structure of the enzyme, the reaction is taking place at the active site. The active site occupies only a small portion of the whole enzyme.
3. Generally active site is situated in a crevice or cleft of the enzyme molecule (Fig. 5.8). To the active site, the specific substrate is bound. The binding of substrate to active site depends on the alignment of specific groups or atoms at active site.
4. During the binding, these groups may realign themselves to provide the unique conformational orientation so as to promote exact fitting of substrate to the active site (Fig. 5.8).
5. The substrate binds to the enzyme at the active site by non-covalent bonds. These forces are hydrophobic in nature.
6. The amino acids or groups that directly participate in making or breaking the bonds (present at the active site) are called catalytic residues or catalytic groups.
7. The active site contains substrate binding site and catalytic site; sometimes these two may be separate.
At equilibrium, forward reaction and backward reaction are equal, so that

\[
\text{Forward reaction } R_1 = K_1 [A] [B]
\]

\[
\text{and backward reaction } R_2 = K_2 [C] [D]
\]

At equilibrium, \( R_1 = R_2 \)

Or, \( K_1 [A] [B] = K_2 [C] [D] \)

Or, \( K_1 = \frac{[C] [D]}{[A] [B]} = K_{eq} \) or \( K_2 \) Equilibrium constant.

determined. If much time is allowed to lapse, the velocity may tend to fall due to decrease in substrate concentration below a critical level.

The velocity is proportional to the concentration of reacting molecules.

\[
\text{If concentration of A or B is doubled, the rate of reaction is also doubled. If concentrations of A and B are doubled together, the velocity becomes 4-fold. (Box 5.5). The following facts can be derived from the equations given in the Box:}
\]

1. The equilibrium constant of the reaction is the ratio of reaction rate constants of forward and backward reactions.

2. At equilibrium, forward and backward reactions are equal. Equilibrium is a dynamic state. Even though no net change in concentrations of substrate and product occurs, molecules are always interconverted.

3. Numerical value of the constant can be calculated by finding the concentrations of substrates and products.

4. If \( K_{eq} \) is more than 1, the forward reaction is favored. In such instances, the reaction is spontaneous and exothermic.

5. Concentration of enzyme does not affect the \( K_{eq} \). Concentration of enzyme certainly increases the rate of reaction; but not the \( K_{eq} \) or the ultimate state. In other words, enzyme makes it quicker to reach the equilibrium. Catalysts increase the rate of reaction, but do not alter the equilibrium.
stopped and product is quantitated (**end point method**). Since the product formed will be proportional to the enzyme concentration, the latter could be assayed.

2. **Effect of Substrate Concentration**

In a series of test tubes, equal volume of enzyme solution is taken, but increasing quantity of substrate is added and the rate of reaction is assayed in each tube. The velocity \((v)\) is expressed in micromoles of substrate converted per minute.

If the velocity is plotted against the substrate concentration, a typical curve (Fig. 5.13A) will be obtained. **As substrate concentration is increased, the velocity is also correspondingly increased in the initial phases; but the curve flattens afterwards.**

This is explained in the Figure 5.13B. At lower concentrations of substrate (point A in the curve), some enzyme molecules are remaining idle. As substrate is increased, more and more enzyme molecules are working. At half-maximal velocity, 50% enzymes are attached with substrate (point B in the curve). As more substrate is added, all enzyme molecules are saturated (point C). Further increase in substrate cannot make any effect in the reaction velocity (point D). **The maximum velocity obtained is called Vmax** (Fig. 5.13B). It represents the maximum reaction rate attainable in presence of excess substrate (at substrate saturation level).

2-A. **Michaelis Constant**

According to Michaelis theory, the formation of enzyme– substrate complex is a reversible reaction, while the breakdown of the complex to enzyme + product is irreversible. (See the derivation of the Michaelis constant in Box 5.6).

In the Fig. 5.14, 50% velocity in Y axis is extrapolated to the corresponding point on X-axis,
2-B. Double Reciprocal Plot

Sometimes it is impractical to achieve high substrate concentrations to reach the maximal velocity conditions. So, \( \frac{1}{2}V_{\text{max}} \) or \( K_M \) may be difficult to determine. Then, the experimental data at lower concentrations is plotted as reciprocals. The straight line thus obtained is extrapolated to get the reciprocal of \( K_M \). This is called *Lineweaver–Burk Plot* or *Double Reciprocal Plot* which can be derived from the Michaelis-Menten equation (For *Lineweaver-Burk equation*, Box 5.9). If we plot \( 
frac{1}{v} \) against \( \frac{1}{[S]} \), it will give a straight line graph as shown in Figure 5.15. Intercept in X axis is minus \( \frac{1}{K_M} \), from which the \( K_M \) can be calculated.

2-C. Dixon Plot

The velocity (\( V \)) is measured at several concentrations of inhibitor (\( I \)), when the substrate (\( S \)) concentration is kept constant. It is used for determining inhibition constants. A plot of \( 
frac{1}{V} \) versus \( [I] \) yields a straight line. The experiment is repeated at different concentrations of substrates.

2-D. Co-operative binding

Some enzymes may not strictly follow the Michaelis-Menten kinetics. When the enzyme has many subunits, and binding of substrate to one unit enhances the affinity for binding to other subunits (co-operative binding), a sigmoid shaped saturation curve is obtained (Fig. 5.16). In such cases, determination of \( K_M \) value, as shown in the previous paragraph, will be invalid. Instead the *Hill equation*, originally described for explaining the oxygen binding to Hemoglobin, is employed (Hill was awarded Nobel prize in 1922).

3. Effect of Concentration of Products

In a reversible reaction, \( S \rightleftharpoons P \), when equilibrium is reached, as per the law of mass action, the reaction
rate is slowed down. So, when product concentration is increased, the reaction is slowed, stopped or even reversed. In inborn errors of metabolism, one enzyme of a metabolic pathway is blocked. For example,

\[
\begin{align*}
E1 & \quad E2 & \quad E3 \\
A \quad \rightarrow B \quad \rightarrow C \quad \rightarrow || \rightarrow D
\end{align*}
\]

If E3 enzyme is absent, C will accumulate, which in turn, will inhibit E2. Consequently, in course of time, the whole pathway is blocked.

4. Effect of Temperature
The velocity of enzyme reaction increases when temperature of the medium is increased; reaches a maximum and then falls (Bell shaped curve). The temperature at which maximum amount of the substrate is converted to the product per unit time is called the **optimum temperature** (Fig. 5.17). As temperature is increased, more molecules get activation energy, or molecules are at increased rate of motion. So their collision probabilities are increased and so the reaction velocity is enhanced. The **temperature coefficient** (Q₁₀) is the factor by which the rate of catalysis is increased by a rise in 10°C. Generally, the rate of reaction of most enzymes will double by a rise in 10°C. But when temperature is more than 50°C, heat denaturation and consequent loss of tertiary structure of protein occurs. So activity of the enzyme is decreased. Most human enzymes have the optimum temperature around 37°C. Certain bacteria living in hot springs will have enzymes with optimum temperature near 100°C.

5. Effect of pH
Each enzyme has an optimum pH, on both sides of which the velocity will be drastically reduced. The graph will show a **bell shaped curve** (Fig. 5.18). The pH decides the charge on the amino acid residues at the active site. The net charge on the enzyme protein would influence substrate binding and catalytic activity. **Optimum pH** may vary depending on the temperature, concentration of substrate, presence of ions etc. Usually enzymes have the optimum pH between 6 and 8. Some important exceptions are **pepsin** (with optimum pH 1-2); **alkaline phosphatase** (optimum pH 9-10) and **acid phosphatase** (4-5).

6. Enzyme Activation
6-A. In presence of certain **inorganic ions**, some enzymes show higher activity. Thus chloride ions activate salivary amylase and calcium activate lipases.

6-B. Another type of activation is the conversion of an inactive **pro-enzyme** or **zymogen** to the active enzyme.

i. By splitting a single peptide bond, and removal of a small polypeptide from **trypsinogen**, the active trypsin is formed. This results in unmasking of the active center.
In competitive inhibition, the inhibitor will be a structural analog of the substrate. There will be similarity in three-dimensional structure between substrate (S) and inhibitor (I). For example, the succinate dehydrogenase reaction is inhibited by malonate (Fig. 5.19).

Competitive inhibition is usually reversible. Or, excess substrate abolishes the inhibition. In the previous example of 100 moles of E and 100 moles of I, if 900 moles of S are added, only 1/10th of enzyme molecules are attached to inhibitor and 90% are working with substrate. Thus 50% inhibition in the first example is now decreased to 10% inhibition (Fig. 5.20).

From the graphs, it is obvious that in the case of competitive inhibition, the Km is increased in presence of competitive inhibitor. Thus competitive inhibitor apparently increases the Km. In other words, the affinity of the enzyme towards substrate is apparently decreased in presence of the inhibitor.

Clinical significance of such inhibition is shown in Box 5.10.

7. Enzyme Inhibition

7-A. Competitive Inhibition

i. Here inhibitor molecules are competing with the normal substrate molecules for binding to the active site of the enzyme, because the inhibitor is a structural analog of the substrate.

\[ E + S \rightleftharpoons E-S \rightarrow E + P \]

\[ E + I \rightleftharpoons E-I \]

ii. Since E-I (enzyme–inhibitor complex) can react only to reform the enzyme and inhibitor, the number of enzyme molecules available for E-S formation is reduced. Suppose 100 molecules of substrate and 100 molecules of inhibitor are competing for 100 molecules of the enzyme. So, half of enzyme molecules are trapped by the inhibitor and only half the molecules are available for catalysis to form the product.

iii. Since effective concentration of enzyme is reduced, the reaction velocity is decreased.

iv. Similarly Trypsin activates chymotrypsinogen, to form active chymotrypsin and two peptides (A and B peptides). As a result, three aminoacid residues, his(57), asp(102) and ser(195) that are far apart in the primary sequence are aligned at the active site and take part in the catalytic process.

v. All the gastrointestinal enzymes are synthesized in the form of pro-enzymes, and only after secretion into the alimentary canal, they are activated. This prevents autolysis of cellular structural proteins.

vi. Coagulation factors are seen in blood as zymogen form, their activation pathways are described in Chapter 28.

vii. Similar activation of precursor protein is taking place in the case of complement components (Chapter 49). These activities are needed only occasionally; but when needed, a large number of molecules are to be produced instantaneously. Hence, the cascade system of chemical amplification of such factors.

7-B. Non-competitive Inhibition (Irreversible)

i. A variety of poisons, such as iodoacetate, heavy metal ions (lead, mercury) and oxidising agents act as irreversible non-competitive
Chapter 5; Enzymology: General Concepts and Enzyme Kinetics

Box 5.10. Clinical Importance of Inhibition

1. **Pharmacological action** of many drugs may be explained by the principle of competitive inhibition. A few important examples are given below:

2. **Sulphonamides**: They are commonly employed antibacterial agents (Fig. 5.21). Bacteria synthesise folic acid by combining PABA with pterooyl glutamic acid. Bacterial wall is impermeable to folic acid. Sulpha drugs, being structural analog of PABA, will inhibit the folic acid synthesis in bacteria, and they die. The drug is nontoxic to human cells, because human beings cannot synthesize folic acid. Preformed folic acid is essential for man. Gerhard Domagk, (Nobel prize 1939).

3. **Methotrexate**: It is 4-amino-N10-methyl folic acid. It is a structural analogue of folic acid, and so can competitively inhibit folate reductase enzyme (Chapter 34). This is essential for DNA synthesis and cell division. Therefore, methotrexate is used as an anticancer drug.

4. **Dicoumarol**: It is structurally similar to vitamin K and can act as an anticoagulant by competitively inhibiting the vitamin K activity (Chapter 33).

5. **Isonicotinic acid hydrazide (INH)**: It is a commonly used antituberculous drug. It is structurally similar to pyridoxal, and prolonged use of INH may cause pyridoxal deficiency and peripheral neuropathy (Chapter 34). A selected list of clinically important drugs working on the principle of competitive inhibition is given in Table 5.5.

**Fig. 5.21. Competitive inhibition**

There is no competition between substrate and inhibitor. See Fig. 5.22.

**ii.** The inhibitor usually binds to a different domain on the enzyme, other than the substrate binding site. Since these inhibitors have no structural resemblance to the substrate, an increase in the substrate concentration generally does not relieve this inhibition. The saturation curve of this type of inhibition is shown in Fig. 5.23. A comparison of the two types of inhibitions is shown in Table 5.6.

Examples are:

- **Cyanide** inhibits cytochrome oxidase.
- **Fluoride** will remove magnesium and manganese ions and so will inhibit the enzyme, enolase, and consequently the glycolysis.
- **Iodoacetate** would inhibit enzymes having-SH group in their active centers.
- **BAL** (British Anti Lewisite; dimercaprol) is used as an antidote for heavy metal poisoning. The heavy metals act as enzyme poisons by reacting with the SH group. BAL has several SH groups with which the heavy metal ions can react and thereby their poisonous effects are reduced.

**iii.** The inhibitor combines with the enzymes by forming a covalent bond and then the reaction becomes irreversible. The velocity (Vmax) is reduced. But **Km value is not changed**, because the remaining enzyme molecules have the same affinity for the substrate.

**iv. Increasing the substrate concentration will abolish the competitive inhibition, but will not abolish non-competitive inhibition.**

**Table 5.5. Clinically useful Competitive Inhibitors**

7-C. Uncompetitive Inhibition
Here inhibitor does not have any affinity for free enzyme. Inhibitor binds to enzyme−substrate complex; but not to the free enzyme. In such cases both $V_{max}$ and $K_m$ are decreased (Fig. 5.24). Inhibition of placental alkaline phosphatase (Regan iso-enzyme) by phenylalanine is an example of uncompetitive inhibition.

7-D. Suicide Inhibition
i. It is a special type of irreversible inhibition of enzyme activity. It is also known as mechanism based inactivation. The inhibitor makes use of the enzyme's own reaction mechanism to inactivate it (mechanism based inactivation).
ii. In suicide inhibition, the structural analog is converted to a more effective inhibitor with the help of the enzyme to be inhibited. The substrate-like compound initially binds with the enzyme and the first few steps of the pathway are catalyzed.
iii. This new product irreversibly binds to the enzyme and inhibits further reactions.
iv. For example, ornithine decarboxylase (ODC) catalyses the conversion of ornithine to putrescine which is necessary for polyamine synthesis (Chapter 16). When the ODC in trypanosoma is inhibited multiplication of the parasite is arrested. Therefore, inhibitors of ODC enzyme such as difluoro methyl ornithine (DFMO) have been found to be effective against trypanosomiasis (sleeping sickness). DFMO is initially inert, but on binding with the enzyme, forms irreversible covalent complex with the co-enzyme (pyridoxal phosphate) and the amino acid residues of the enzyme. In mammalian cells, the turnover rate of ODC is very high, and so the inhibition by DFMO is only transient. So DFMO kills the parasites with no side-effects to the patient.
v. A similar mechanism is observed in the case of Allopurinol which is oxidised by xanthine oxidase to alloxanthine that is a strong inhibitor of xanthine oxidase (Chapter 39).

vi. The anti-inflammatory action of aspirin is also based on the suicide inhibition. Arachidonic acid is converted to prostaglandin by the enzyme cyclo-oxygenase (Chapter 13). Aspirin acetylates a serine residue in the active center of cyclo-oxygenase, thus prostaglandin synthesis is inhibited, and so inflammation subsides.

7-E. Allosteric Regulation
i. Allosteric enzyme has one catalytic site where the substrate binds and another separate allosteric site where the modifier binds (allo = other) (Fig. 5.25).
ii. Allosteric and substrate binding sites may or may not be physically adjacent.
iii. The binding of the regulatory molecule can either enhance the activity of the enzyme (allosteric activation), or inhibit the activity of the enzyme (allosteric inhibition).
iv. In the former case, the regulatory molecule is known as the positive modifier and in the latter case as the negative modifier.
v. The binding of substrate to one of the subunits of the enzyme may enhance substrate binding by other subunits. This effect is said to be positive co-operativity. If the binding of substrate to one of the subunits decreases the avidity of substrate binding by other sites, the effect is called negative co-operativity.
vi. In most cases, a combination is observed, resulting in a sigmoid shaped curve (Fig. 5.26). Salient features of allosteric regulation are enumerated in Box 5.11.

Box 5.11. Salient Features, Allosteric Inhibition
1. The inhibitor is not a substrate analog.
2. It is partially reversible, when excess substrate is added.
3. Km is usually increased.
4. Vmax is reduced.
5. The effect of allosteric modifier is maximum at or near substrate concentration equivalent to Km (Fig. 5.26). When an inhibitor binds to the allosteric site, the configuration of catalytic site is modified such that substrate cannot bind properly.
6. Most allosteric enzymes possess quaternary structure. They are made up of subunits, e.g. Aspartate transcarbamoylase has 6 subunits and pyruvate kinase has 4 subunits. Examples of allosteric enzymes are shown in Table 5.7.

Fig. 5.25. Action of allosteric enzymes

7-F. Key enzymes
i. Body uses allosteric enzymes for regulating metabolic pathways. Such a regulatory enzyme in a particular pathway is called the key enzyme or rate limiting enzyme.
ii. The flow of the whole pathway is constrained as if there is a bottleneck at the level of the key enzyme.
iii. The allosteric inhibitor is most effective when substrate concentration is low. This is metabolically very significant. When more substrate molecules are available, there is less necessity for stringent regulation. Two best examples are given in detail below:
a. ALA synthase
Succinyl CoA + -------------> delta- amino-Glycine
   levulinic acid (ALA)
This is the first step in heme biosynthesis. The end product, heme will allosterically inhibit the ALA synthase. This enzyme is the key enzyme of heme synthesis (Chapter 21). Similarly,
b. Aspartate transcarbamoylase
Carbamoyl phosphate ------> Carbamoyl
   + Aspartate aspartate + Pi
This is the first step in the pathway which finally produces cytidine triphosphate (CTP) (Chapter 39).
56  Textbook of Biochemistry; Section A: Chemical Basis of Life

CTP, the end product will allosterically inhibit aspartate transcarbamoylase. There is no structural resemblance between aspartate and CTP. Other such allosteric enzymes are listed in Table 5.7.

7-G. Feedback Inhibition
The term feedback inhibition or end-product inhibition means that the activity of the enzyme is inhibited by the final product of the biosynthetic pathway.

\[ A \xrightarrow{E_1} B \xrightarrow{E_2} C \xrightarrow{E_3} D \]

In this pathway, if D inhibits E1, it is called feedback inhibition. For example, AMP inhibits the first step in purine synthesis (Chapter 39). Usually such end product inhibition is effected allosterically.

Table 5.7. Examples of allosteric enzymes

8-A. Induction
Induction is effected through the process of derepression. The inducer will relieve the repression on the operator site and will remove the block on the biosynthesis of the enzyme molecules. Classical example is the induction of lactose-utilizing enzymes in the bacteria when the media contains lactose in the absence of glucose (details in Chapter 42). There will be a minimal level of the enzyme inside the cell, but in presence of the inducer, the level will go up to thousand or million times within hours. By this mechanism nutrients are utilized most efficiently; while the enzyme synthesis is kept to the optimum. Tryptophan pyrrolase and transaminases are induced by glucocorticoids. Glucokinase is induced by insulin. ALA synthase is induced by barbiturates.

8-B. Repression
Even though both inhibition and repression reduce the enzyme velocity, the mechanisms are different. In the case of inhibition, the inhibitor acts on the enzyme directly; the inhibitory activity is noticed as soon as the inhibitor is added; and the number of enzyme molecules is not changed by the inhibitor.

On the contrary, repressor acts at the gene level; the effect is noticeable only after a lag period of hours or days; and the number of enzyme molecules is reduced in the presence of repressor molecule. Details of repression are given in Chapter 42. A summary of the mechanism of repression is given in Figure 5.27.

The key enzyme of heme synthesis, ALA synthase is autoregulated by the heme by means of repression. The structural gene is transcribed and later translated to produce the enzyme molecules. The transcription process starts at the operator site when it is free. When heme is not available, this operator site is open, and therefore the enzyme is being synthesized. When heme is produced in plenty, heme acts as the co-repressor in combination with an apo-repressor, heme will shut off the operator site. Now further production of ALA synthase is stopped.

9. Covalent Modification
The activity of enzymes may be increased or decreased by covalent modification. It means, either addition of a group to the enzyme protein by a covalent bond; or removal of a group by cleaving a covalent bond.

Zymogen activation by partial proteolysis is an example of covalent activation. Addition or removal of a particular group brings about covalent
Commonest type of covalent modification is the reversible **protein phosphorylation**. The phosphate group may be attached to serine, threonine or tyrosine residues. When hormone binds to the membrane bound receptor, hormone-receptor complex (HR) is formed. The enzyme adenylate cyclase is activated. This activation is mediated through a G protein (Chapter 44). The active adenylate cyclase converts ATP to cyclic AMP (cAMP) which acts as a second messenger. It activates protein kinase (serine/threonine kinase) by binding to the regulatory subunit of the enzyme. The active catalytic subunit will phosphorylate the enzyme. In some cases, the receptor itself has tyrosine kinase activity which is switched on when hormone binds to receptor, e.g. insulin. Table 5.8 gives a partial list of examples of such activation by phosphorylation/dephosphorylation.

**ADP ribosylation** is another covalent modification, where an ADP-ribose from NAD+ is added to enzyme / protein. For example, ADP ribosylation of alpha subunit of G-protein leads to inhibition of GTPase activity; hence G protein remains active. Cholera toxin and pertussis toxin act through ADP ribosylation. ADP ribosylation of glyceraldehyde-3-phosphate dehydrogenase results in inhibition of glycolysis.

**10. Stabilization**

Enzyme molecules undergo usual wear and tear and finally get degraded. Such degradation if prevented can lead to increased overall enzyme activity. This is called stabilization of enzyme. Degradation of Tryptophan pyrrolase is retarded by tryptophan. Phospho fructokinase is stabilized by growth hormone. Enzymes having SH-groups (Papain, Urease, Succinate dehydrogenase) are stabilized by glutathione (G-SH).

**11. Compartmentalization**

The activity of enzymes catalysing the different steps in a metabolic pathway may be regulated by compartmentalization of enzymes. Certain enzymes of the pathway may be located in mitochondria whereas certain other enzymes of the same pathway are cytoplasmic. For example heme synthesis (Chapter 21), urea cycle (Chapter 14) gluconeogenesis (Chapter 9). The intermediates have to be shuttled across the mitochondrial membrane for this purpose which provides a point where controls can be exerted.

### SPECIFICITY OF ENZYMES

**1. Absolute Specificity**

Some enzymes are absolutely specific. For example, hydrolysis of urea to ammonia and carbondioxide is catalyzed by urease. Urea is the only substrate for **urease**. Thiourea, though structurally similar to urea, will not act as the substrate for urease. Similarly glucose oxidase will oxidise only beta-D-glucose and no other isomeric form. Thus, these enzymes show absolute specificity.

**2. Bond Specificity**

Most of the proteolytic enzymes are showing group (bond) specificity. For example, trypsin can hydrolyse peptide bonds formed by carboxyl groups of arginine or lysine residues in any proteins.

**3. Group Specificity**

One enzyme can catalyse the same reaction on a group of structurally similar compounds, e.g. hexokinase can catalyse phosphorylation of glucose, galactose and mannose.

**4. Stereospecificity**

Human enzymes are specific for L-amino acids and D-carbohydrates. Fumarase will hydrate fumaric acid in the L-form.

**Fig. 5.27. Repression of ALA synthase**
Enzymes are assayed by taking the serum sample and adding a suitable substrate. After the incubation time, the mixture is assayed for the product formed.

NAD\(^+\) or NADP\(^+\) dependent enzymes are assayed by spectrophotometry, as the reduced form of these co-enzymes will absorb light at a wavelength of 340 nm; but their oxidised forms will not absorb light. A reaction of our interest can be suitably coupled with another reaction utilising NAD\(^+\) or NADP\(^+\) and then the reaction rate can be assessed.

**Enzyme activity** is expressed as micromoles of substrate converted to product per minute under specified assay conditions. One standard unit (or International Unit) of enzyme activity (U) is the amount of enzyme that will convert one micromole of substrate per minute per litre of sample and is abbreviated as U/L.

The modern method of expression of enzyme activity is in Katals (kat). One Katal (catalytic activity) is defined as the number of mol of substrate transformed per second per litre of sample (Kcat = Vmax divided by the number of active sites). (60 U = 1 μkat and 1 nkat = 0.06 U) (1 I.U. = 1 μmol/min = 16.67 nkat). When expressed in katals, the activity of different enzymes can be compared.

**Catalytic efficiency** is expressed as the ratio of Kcat divided by Km.

**Specific activity** is the number of enzyme units present per milligram of protein (Vmax divided by the protein concentration). It is a measure of the purity of the preparation.

**Turnover number** is the number of substrate molecules transformed per unit time by a single enzyme molecule or by a single catalytic site (Vmax divided by number of enzyme molecules). This is estimated in purified preparations of enzymes. The turnover number of catalase is 40,000,000; that of carbonic anhydrase is 400,000 and fumarase is 800.

**Body Metabolism is controlled by enzymes**

In a pipe, theoretically water can flow both ways, but practically the flow is **unidirectional**. In the same way, although most of the individual enzyme activities are readily reversible, the pathway as a whole, tends to lead towards the final product.

In the reaction series, A ----> -----> B -----> C, as soon as C is produced, it is utilized for something else, so that the reactions as a whole, tend to go in the forward direction only. True equilibrium of chemical reactions in the cell is achieved only when the cell is dead. In other words, living cells avoid the state of chemical equilibrium. At the same time, if we analyse a particular metabolite, the concentration is more or less kept constant over very long periods. This is called **steady-state system**. For example, blood glucose level is kept within a narrow range, because the factors which tend to increase the level are at dynamic equilibrium with the factors which try to decrease the level.

Deficiency of the enzyme or its activity will lead to genetic defects, inborn errors of metabolism. Such deficiency may be due to genetic mutation or by infections.

**Drug Metabolism**

Drugs act on enzymes present in human beings or in pathogens. Penicillin blocks cell wall synthesis in bacteria by irreversible binding of the enzyme transpeptidase. Many bacteria, however, produce beta-lactamases that hydrolyse the penicillin. Another example is that the drug 5-fluoro uracil is metabolised inside human body into deoxy fluro uridylic acid, which inhibits thymidylate synthase, and hence acts as an anticancer drug.

**Drug Designing**

With the help of computer programming, it is nowadays possible to get an idea of the three-dimensional structure of active site of enzyme, which exactly fits the substrate. With this knowledge, research workers could make theoretical models of hundreds of different inhibitors. The best few are selected and then experiments are done in vivo. This approach to drug designing is getting rapid momentum in medical field.

**Processive enzymes**

They continue to act on a particular substrate; and do not dissociate between repetitions of the catalytic event. Examples are DNA polymerase, RNA polymerase, glycogen synthase and fatty acid synthase.

![Fig. 5.28. Example of stereospecificity](image-url)
Multi enzyme complexes
Generally enzymes are diffusion limited, meaning that the rate of reaction is limited by the rate at which substrate molecules diffuse through solution and reach the active site of the enzyme. In a series of reactions, the product of the first enzyme is diffused into the surrounding medium, later reaches to the second enzyme. This may act as a hindrance for the smooth and efficient work of the enzymes in a metabolic pathway. Nature circumvents this problem, by keeping all the enzymes of a reaction sequence into a multi enzyme complex, so that the product of the first reaction is immediately transferred to the second enzyme and so on. Examples are fatty acid synthase (Chapter 11) pyruvate dehydrogenase, alpha-keto glutarate dehydrogenase, acetyl CoA carboxylase, glycine cleavage system and pyrimidine nucleotide synthesis (Chapter 39).

Sequential reactions or single displacement reactions
In such cases, both substrates are first combined with the enzyme to form a ternary complex, then catalysis is followed. Most of the NAD⁺ dependent reactions follow this principle.

Ping Pong reactions or double displacement reactions
They involve a transient modified form of the enzyme. The group undergoing transfer is first taken from one substrate A, added to the enzyme, subsequently the group is taken from the modified enzyme, and added to another substrate. Examples are aminotransferases.

Single Molecule Enzymology
Recent advancement in Nanotechnology have made it possible to observe catalysis by individual enzyme and substrate molecules by fluorescence microscopy. Even the rate of single catalytic events and sometimes individual steps in catalysis is measured by this process.

ISO-ENZYMES
They are physically distinct forms of the same enzyme activity. Multiple molecular forms of an enzyme are described as iso-enzymes or isozymes. If 50 paise coins are examined carefully, there will be minor variations of ridges on the rims and number of dots below the year. In the market all these coins have the same face value; but to an experienced numismatist, these variations will explain from which mint it was produced. In the same way, different molecular forms of the same enzyme synthesized from various tissues are called iso-enzymes. Hence study of iso-enzymes is very useful to understand diseases of different organs. If the subunits are all the same, the protein is a homomultimer represented by a single gene. If the subunits are different, protein is said to be a heteromultimer, produced by different genes.

Iso-enzymes may be Formed in Different Ways
1. They may be products of different genes (more than one locus) in which case they are known as true iso-enzymes. The genes may be located on different chromosomes, e.g. salivary and pancreatic amylase.
2. In certain cases, all the different forms are present in the same individual, e.g. Lactate dehydrogenase (LDH) has 5 iso-enzymes and all are seen in all persons in the population. (Chapter 23).
3. The same locus of the gene may have different alleles (alternate forms). Such allelic iso-enzymes are called allozymes. In this case, only one form will be present in one individual; but all the different forms will be seen in total population. For example, more than 400 distinct forms of glucose-6-phosphate dehydrogenase (GPD) have been identified; all of them are produced by the same locus on the X-chromosome. When iso-enzymes due to variation at a single locus occur with appreciable frequency (more than 1% in population), it is said to be polymorphism.
4. Molecular heterogeneity of enzymes may also be produced after the protein is synthesized (post-translational modification). These are called iso-forms, e.g. sialic acid content in alkaline phosphatase (ALP) iso-enzymes. Different types of iso-forms may be seen in the same individual.

Identification of Iso-enzymes
1. In Agar gel or polyacrylamide gel electrophoresis, the iso-enzymes have different mobility. LDH, CK and ALP iso-enzymes can be separated by electrophoresis.
2. Heat stability: one of the iso-enzymes may be easily denatured by heat, e.g. bone iso-enzyme of ALP (BALP).
3. Inhibitors: one of the iso-enzymes may be sensitive to one inhibitor, e.g. tartrate labile ACP.
4. Km value or substrate specificity may be different for iso-enzymes. E.g. glucokinase has high Km and hexokinase has low Km for glucose.
5. Cofactor requirements may be different for iso-enzymes. Mitochondrial isocitrate dehydrogenase is NAD⁺ dependent and the cytoplasmic iso-enzyme is NADP⁺ dependent.
6. Tissue localization may be different for iso-enzymes. H4 form of LDH is present in heart, while M4 variety is seen in skeletal muscle.
7. Specific antibodies may identify different types of iso-enzymes. For example, CK iso-enzymes are separated by antibodies.

Related topics
Iso-enzymes of LDH, CK, ALP; enzymes used for therapeutic and diagnostic purposes and Immobilized enzymes are described in Chapter 23. Enzyme linked immunosorbent assay as well as Protein purification techniques are summarized in Chapter 54.
CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Nomenclature and classification of sugars
2. Stereoisomers
3. Glucose, Mannose and Galactose
4. Fructose
5. Reactions of monosaccharides
6. Glycosides
7. Amino sugars and deoxy sugars
8. Pentoses
9. Sucrose, lactose and maltose
10. Starch, glycogen and cellulose
11. Heteroglycans, mucopolysaccharides

Functions of Carbohydrates
1. Carbohydrates are the main sources of energy in the body. Brain cells and RBCs are almost wholly dependent on carbohydrates as the energy source. Energy production from carbohydrates will be 4 k calories/g (16 k Joules/g).
2. Storage form of energy (starch and glycogen).
3. Excess carbohydrate is converted to fat.
4. Glycoproteins and glycolipids are components of cell membranes and receptors.
5. Structural basis of many organisms: Cellulose of plants; exoskeleton of insects, cell wall of microorganisms, mucopolysaccharides as ground substance in higher organisms.

The general molecular formula of carbohydrate is Cn(H2O)n. For example, glucose has the molecular formula C6H12O6. Carbohydrates are polyhydroxy aldehydes or ketones or compounds which yield these on hydrolysis (Fig. 6.1).

NOMENCLATURE
Molecules having only one actual or potential sugar group are called monosaccharides (Greek, mono = one; saccharide = sugar). They cannot be further hydrolysed into smaller units. When two monosaccharides are combined together with elimination of a water molecule, it is called a disaccharide (e.g. C12H22O11). Trisaccharides contain three sugar groups. Further addition of sugar groups will correspondingly produce tetrasaccharides, pentasaccharides and so on, commonly known as oligosaccharides (Greek, oligo = a few). When more than 10 sugar units are combined, they are generally named as polysaccharides (Greek, poly = many). Polysaccharides having only one type of monosaccharide units are called homopolysaccharides and those having different monosaccharide units are heteropolysaccharides.

Sugars having aldehyde group are called aldoses and sugars with keto group are ketoses. Depending on the number of carbon atoms, the monosaccharides are named as triose (C3), tetrose (C4), pentose (C5), hexose (C6), heptose (C7) and so on. Commonly occurring monosaccharides are given in Table 6.1.

STEREOISOMERS
Compounds having same structural formula, but differing in spatial configuration are known as stereoisomers. While writing the molecular formula of monosaccharides, the spatial arrangements of H and OH groups are important, since they contain asymmetric carbon atoms. Asymmetric carbon means that four different groups are attached to the same carbon. The reference molecule is glyceraldehyde (glycerose) which has a single asymmetric carbon atom (Fig. 6.2).
The number of possible stereoisomers depends on the number of asymmetric carbon atoms by the formula $2^n$, where $n$ is the number of asymmetric carbon atoms.

Reference Carbon Atom of Sugars
The configuration of H and OH groups at the second carbon atom of glyceraldehyde (Fig. 6.2) may be noticed. The two mirror forms are denoted as D- and L-varieties. All monosaccharides can be considered as molecules derived from glyceraldehyde by successive addition of carbon atoms. Therefore, penultimate carbon atom is the reference carbon atom for naming the mirror images (Fig. 6.3). This is also referred to as absolute configuration.

D and L Isomerism of Glucose
With reference to the penultimate carbon atom (i.e. C5 in the case of glucose), the configuration of H and OH groups is changed and two mirror images are produced (Fig. 6.3). It may be noted that in D and L varieties, the groups in 2nd, 3rd, 4th and 5th carbon atoms are totally reversed, so as to produce the mirror images. These two forms are also stereoisomers. D sugars are naturally occurring sugars and body can metabolise only D sugars.

Optical Activity
The presence of asymmetrical carbon atom causes optical activity. When a beam of plane-polarized light is passed through a solution of carbohydrates, it will rotate the light either to right or to left. Please note that the D- and L-notation has no bearing with the optical activity. Depending on the rotation, molecules are called dextrorotatory (+) (d) or levorotatory (-) (l). Thus D-glucose is dextrorotatory but D-fructose is levorotatory. Equimolecular mixture of optical isomers has no net rotation (racemic mixture). Heyrovsky was awarded Nobel prize in 1924 for polarographic analysis of sugars.

1. Diastereo-isomers of Glucose
Configurational changes with regard to C2, C3 and C4 will produce eight different monosaccharides. Out of these, only 3 are seen in human body. They are Glucose, Galactose and Mannose. See Fig. 6.4 and Table 6.2.

There are 8 diastereoisomers for aldohexoses. With reference to C5, all of them will have D and L forms. Hence, the molecular formula of hexose (C₆H₁₂O₆) represents 16 different monosaccharides, due to spatial arrangement of constituent groups.

**Glucose** is the most predominant sugar in human body. It is the major source of energy. It is present in blood (Table 6.2). D-glucose is dextrorotatory. In clinical practice, it is often called as dextrose (Box 6.5).

**Galactose** is a constituent of lactose (milk sugar) and glycoproteins. Galactose is epimerised to glucose in liver and then utilized as a fuel. The term galactose is derived from Greek word gala, meaning milk.

**Mannose** is a constituent of many glycoproteins. Mannose was isolated from plant mannans; hence the name.

---

**Box 6.1. Practical Importance of Mutarotation**

In a clinical laboratory, once a technician freshly prepared a standard solution (100 mg/100 ml) of glucose. She compared it with another standard solution similarly prepared one week ago. The comparison was done by glucose-oxidase method. To her surprise, the freshly prepared solution showed only one-tenth strength of the old solution. Testing a second time, she got the same results. So she asked for the help of her boss, an MD in Biochemistry, who suggested to keep the new solution, overnight in fridge. The next day, both one-week-old solution and the new (kept overnight) solution gave identical results. The technician was not able to explain the reason for this change. Can you explain?

**Answer:** When glucose solution is freshly prepared, most of the molecules are in α form. On keeping the solution for 18 hours, "mutarotation" takes place, and 63% molecules are changed to β configuration. The glucose-oxidase enzyme preferentially acts on the β form. Hence, freshly prepared solutions will give lower values.

---

2. **Epimerism of Aldoses**

When sugars are different from one another, only in configuration with regard to a single carbon atom, other than the reference carbon atom, they are called epimers. For example, glucose and mannose are an epimeric pair which differ only with respect to C2. Similarly, galactose is the 4th epimer of glucose. (Fig. 6.4). Galactose and mannose are not epimers but diastereo-isomers.

3. **Anomerism of Sugars**

When D glucose is crystallized at room temperature, and a fresh solution is prepared, its specific rotation of polarized light is +112°; but after 12-18 hours it changes to +52.5°. If initial crystallization is taking place at 98°C and then solubilized, the specific rotation is found to be +19°, which also changes to +52.5° within a few hours. This change in rotation with time is called mutarotation.

This is explained by the fact that D-glucose has two anomers, alpha and beta varieties. These anomers are produced by the spatial configuration with reference to the first carbon atom in aldoses and second carbon atom in ketoses. (Fig. 6.5). Hence, these carbon atoms are known as anomeric carbon atoms. Thus α-D-glucose has specific rotation of +112° and β-D-glucose has +19°. Both
undergo mutarotation and at equilibrium one-third molecules are alpha type and 2/3rd are beta variety to get the specific rotation of +52.5°. The hemiacetal structure of anomeric forms of glucose are shown in Figure 6.5.

The differences between α and β anomeric forms are dependent on the 1st carbon atom only. In the previous section 16 stereoisomers of glucose are described. Each of them will have 2 anomers; and hence there are a total of 32 isomers for glucose.

**Three Representations of Glucose Structure**
The 1st carbon, aldehyde group is condensed with the hydroxyl group of the 5th carbon to form a ring. Ring structure represents hemiacetal form, which is the condensation of an aldehyde (or keto) with a hydroxyl group.

The open chain projection formula and hemiacetal ring structure of glucose were proposed by Emil Fischer in 1883, and hence called Fischer's formula. Fischer was awarded Nobel prize in 1902.

Later it was shown that the glucose exists in biological systems, not as a rectangle, but as a pyranose ring (Fig. 6.6). This was established by Sir Walter Haworth in 1925 who got Nobel prize in 1937. Therefore the structure of glucose may be given as the following 3 forms, each successive form adding more details (Fig. 6.7).

**Fructose is a Ketohexose**
In fructose, the keto group is on the 2nd carbon atom. Thus second carbon atom is the anomeric carbon atom. Fructose has 4 isomers. Each of them has D and L forms with regard to 5th carbon atom. Fructose has the same molecular formula as glucose, but differs in structural formula. So glucose and fructose are functional group (aldose-ketose) isomers. D fructose is levorotatory. Only D variety is seen in biological systems. Fructose remains predominantly as furanose ring structure (Fig. 6.8). Fructose is a major constituent of honey.

**REACTIONS OF MONOSACCHARIDES**
In sugars, the following 3 properties will be seen together:
Fig. 6.8. Different representations of D-fructose

A. Mutarotation  
B. Reducing property  
C. Formation of osazone with phenylhydrazine.

1. Enediol Formation
In mild alkaline solutions, carbohydrates containing a free sugar group (aldehyde or keto) will tautomerise to form enediols, where two hydroxyl groups are attached to the double-bonded carbon atoms. In mild alkaline conditions, glucose is converted into fructose and mannose. The interconversion of sugars through a common enediol form is called Lobry de Bruyn-Van Ekenstein transformation (Fig. 6.10). Since enediols are highly reactive, sugars are powerful reducing agents in alkaline medium. When oxidising agents like cupric ions are present, sugars form a mixture of carboxylic acids by breaking at the double bonds.

2. Benedict’s Reaction
Benedict’s reagent is very commonly employed to detect the presence of glucose in urine (glucosuria). It is a standard laboratory test employed to diagnose diabetes mellitus. Benedict’s reagent contains sodium carbonate, copper sulphate and sodium citrate. In alkaline medium, sugars form enediol, cupric ions are reduced, correspondingly sugar is oxidized (Fig. 6.9). **Glucose is a reducing sugar.** (Fig. 6.19B). Any sugar with free aldehyde/keto group will reduce the Benedict’s reagent. Therefore, this is not specific for glucose. Reducing substances in urine are described in Chapter 24.

3. Osazone Formation
All reducing sugars will form osazones with excess of phenylhydrazine when kept at boiling temperature. Osazones are insoluble. Each sugar will have characteristic crystal form of osazones. The

**Fig. 6.11. Shape of osazones under microscope**
Chapter 6; Chemistry of Carbohydrates

5. Furfural Derivatives

Monosaccharides when treated with concentrated sulphuric acid undergo dehydration with the removal of 3 molecules of water. Therefore hexoses give hydroxymethyl furfural and pentoses give galactalonic acid.

The furfural derivative can condense with phenolic compounds to give coloured products. This forms the basis of Molisch test. It is a general test for carbohydrates.

6. Reduction to Form Alcohols

i. When treated with reducing agents such as sodium amalgam, hydrogen can reduce sugars. Aldose yields corresponding alcohol. Ketose forms two alcohols, because of appearance of a new asymmetric carbon atom in this process (see Fig. 6.13).

ii. Glucose is reduced to sorbitol; mannose to mannitol; while fructose becomes sorbitol and mannitol (Fig. 6.13). Galactose is reduced to dulcitol and ribose to ritol.

Sorbitol, mannitol and dulcitol are used to identify bacterial colonies. Mannitol is also used to reduce intracranial tension by forced diuresis. The osmotic effect of sorbitol and dulcitol produces changes in tissues when they

Fig. 6.12. Oxidative products of glucose

Fig. 6.13. Reduction of sugar to alcohol
Amino Sugars
i. Amino groups may be substituted for hydroxyl groups of sugars to give rise to amino sugars. Generally, the amino group is added to the second carbon atom of hexoses (Fig. 6.15).

ii. Amino sugars will not show reducing property. They will not produce osazones.

iii. Glucosamine is seen in hyaluronic acid, heparin and blood group substances. Galactosamine is present in chondroitin of cartilage, bone and tendons. Mannosamine is a constituent of glycoproteins.

iv. The amino group in the sugar may be further acetylated to produce N-acetylated sugars such as N-acetyl-glucosamine (GluNac) (Fig. 6.16), N-acetyl-galactosamine (GalNac), etc. which are important constituents of glycoproteins, mucopoly-saccharides and cell membrane antigens.

Deoxy Sugars
i. Oxygen of the hydroxyl group may be removed to form deoxy sugars. Some biologically
DISACCHARIDES

When two monosaccharides are combined together by glycosidic linkage, a disaccharide is formed. The important disaccharides are

1. Sucrose
2. Maltose and isomaltose
3. Lactose.

**Sucrose**

i. It is the sweetening agent known as cane sugar. It is present in sugarcane and various fruits.

ii. Sucrose contains glucose and fructose. Sucrose is not a reducing sugar; and it will not form osazone. This is because the linkage involves first carbon of glucose and second carbon of fructose, and free reducing groups are not available (Fig. 6.19A).

v. When sucrose is hydrolysed, the products have reducing action. A sugar solution which is originally nonreducing, but becomes reducing after hydrolysis, is identified as sucrose (specific sucrose test) (Fig. 6.19B).

**Pentoses**

i. They are sugars containing 5 carbon atoms.

ii. **Ribose** (Fig. 6.18) is a constituent of RNA. Ribose is also seen in co-enzymes such as ATP and NAD. **Deoxyribose** is seen in DNA (Fig. 6.18).

iii. **Ribulose** is an intermediate of HMP shunt pathway. **Arabinose** is present in cherries and seen in glycoproteins of the body. The name arabinose is derived as it was originally isolated from gum arabic.

iv. **Xylose** is seen in proteoglycans. **Xylulose** is an intermediate of uronic acid pathway.
vi. Hydrolysis of sucrose (optical rotation +66.5°) will produce one molecule of glucose (+52.5°) and one molecule of fructose (−92°). Therefore the products will change the dextrorotation to levorotation, or the plane of rotation is inverted. Equimolecular mixture of glucose and fructose thus formed is called invert sugar. The enzyme producing hydrolysis of sucrose is called sucrase or invertase. Honey contains invert sugar. Invert sugar is sweeter than sucrose.

Lactose
i. It is the sugar present in milk. It is a reducing disaccharide. On hydrolysis lactose yields glucose and galactose. Beta glycosidic linkage is present in lactose.

ii. The structure is given in Figure 6.20. The anomic carbon atom of beta-galactose is attached to the 4th hydroxyl group of glucose through beta-1,4 glycosidic linkage. The lactose may be alpha or beta variety, depending on the configuration of 1st carbon of glucose moiety.

Isomaltose
It is also a reducing sugar. It contains 2 glucose units combined in alpha -1,6 linkage. Thus first carbon of one glucose residue is attached to the sixth carbon of another glucose through a glycosidic linkage (Fig. 6.22). Partial hydrolysis of glycogen and starch produces isomaltose. The enzyme oligo-1,6-glucosidase present in intestinal juice can hydrolyse isomaltose into glucose units.

Box 6.2. Lactose and Lactate are Different
Lactose is the milk sugar; a disaccharide made of galactose and glucose. Lactate or Lactic acid is a product of anaerobic metabolism of glucose.
Chapter 6; Chemistry of Carbohydrates

Fig. 6.23. Branched glycogen molecule

The salient features of important sugars are shown in Box 6.3.

**POLYSACCHARIDES**

These are polymerized products of many mono-saccharide units. They may be

1. **Homoglycans** are composed of single kind of monosaccharides, e.g. starch, glycogen and cellulose.

2. **Heteroglycans** are composed of two or more different monosaccharides, e.g. hyaluronic acid, chondroitin sulphate.

1. **Starch**

   **A. Structure of Starch**
   
   i. It is the reserve carbohydrate of plant kingdom.

   ii. **Sources:** Potatoes, tapioca, cereals (rice, wheat) and other food grains.

   iii. Starch is composed of amylose and amylopectin. When starch is treated with boiling water, 10-20% is solubilized; this part is called amylose. Amylose is made up of glucose units with alpha-1,4 glycosidic linkages (Fig. 6.21) to form an unbranched long chain with a molecular weight 400,000 D or more.

   iv. The insoluble part absorbs water and forms paste like gel; this is called amyllopectin. Amylopectin is also made up of glucose units, but is highly branched with molecular weight more than 1 million. The branching points are made by alpha-1,6 linkage (similar to isomaltose, Fig. 6.22).

   **B. Hydrolysis of Starch**

   i. Starch will form a blue colored complex with iodine; this color disappears on heating and reappears when cooled. This is a sensitive test for starch. Starch is non reducing because the free sugar groups are negligible in number.

   ii. When starch is hydrolysed by mild acid, smaller and smaller fragments are produced.

   iii. Thus hydrolysis for a short time produces amylodextrin which gives violet color with iodine and is nonreducing. Further hydrolysis produces erythrodextrin which gives red color with iodine and mild reduction of Benedict's solution. Later achrodextrins (no color with iodine, but reducing) and further on, maltose (no color with iodine, but powerfully reducing) are formed on continued hydrolysis.

   **C. Action of Amylases on Starch**

   i. Salivary amylase and pancreatic amylase are alpha-amylases, which act at random on alpha-1,4 glycosidic bonds to split starch into smaller units (dextrins), and finally to alpha-maltose.

   ii. Beta-amylases are of plant origin (almond, germinating seeds, etc) which split starch to form beta-maltose. They act on amylose to split maltose units consecutively. Thus the enzyme starts its action from one end.

   iii. When beta-amylase acts on amylopectin, maltose units are liberated from the ends of the branches of amylopectin, until the action of enzyme is blocked at the 1,6-glycosidic linkage. The action of beta-amylase stops at branching points, leaving a large molecule, called limit dextrin or residual dextrin.

2. **Glycogen**

   i. It is the reserve carbohydrate in animals. It is stored in liver and muscle. About 5% of weight of liver is made up by glycogen. Excess carbohydrates are deposited as glycogen.

   ii. Glycogen is composed of glucose units joined by alpha-1,4 links in the straight chains. It also

- Glucose + Glucose = Maltose (reducing)
- Glucose + Fructose = Sucrose (nonreducing)
has alpha-1,6 glycosidic linkages at the branching points (Fig. 6.23). Molecular weight of glycogen is about 5 million. Innermost core of glycogen contains a primer protein, Glycogenin. Glycogen is more branched and more compact than amylopectin.

3. Cellulose
   i. It is the supporting tissues of plants. Cellulose constitutes 99% of cotton, 50% of wood and is the most abundant organic material in nature.
   ii. It is made up of glucose units combined with beta-1,4 linkages. It has a straight line structure, with no branching points. Molecular weight is in the order of 2 to 5 million.
   iii. Beta-1,4 bridges are hydrolysed by the enzyme cellulobiose. But this enzyme is absent in animal and human digestive system, and hence cellulose cannot be digested.
   iv. Herbivorous animals have large caecum, which harbor bacteria. These bacteria can hydrolyse cellulose, and the glucose produced is utilized by the animal. White ants (termites) also digest cellulose with the help of intestinal bacteria.
   v. Cellulose has a variety of commercial applications, as it is the starting material to produce fibres, cellulosoids, nitrocellulose and plastics.

4. Inulin
   It is a long chain homoglycan composed of D-fructose units with repeating beta-1,2 linkages. It is the reserve carbohydrate present in various bulbs and tubers such as chicory, dahlia, dandelion, onion, garlic. It is clinically used to find renal clearance value and glomerular filtration rate. Inulin and Insulin are different (Box 6.4).

5. Dextran
   These are highly branched homopolymers of glucose units with 1-6, 1-4 and 1-3 linkages. They are produced by microorganisms. They have molecular weight 1 million to 4 millions. Since they will not easily go out of vascular compartment, they are used for intravenous infusion as plasma volume expander for treatment of hypovolemic shock. It may be noted that dextrans are different from previously described dextrins (Box 6.5).

6. Chitin
   It is present in exoskeletons of crustacea and insects. It is composed of units of N-acetyl-glucosamine with beta-1,4 glycosidic linkages.

HETEROGLYCANs
These are polysaccharides containing more than one type of sugar residues. Examples are:

4. Agar
   i. It is prepared from sea weeds. It contains galactose, glucose and other sugars.
   ii. It is dissolved in water at 100°C, which upon cooling sets into a gel. Agar cannot be digested by bacteria and hence used widely as a supporting agent to culture bacterial colonies. Agar is used as a supporting medium for immuno-diffusion and immuno-electrophoresis.
   iii. Agarose is made up of galactose combined with 3,6-anhydrogalactose units; it is used as matrix for electrophoresis (Chapter 54).

5. Dextran
   These are highly branched homopolymers of glucose units with 1-6, 1-4 and 1-3 linkages. They are produced by microorganisms. They have molecular weight 1 million to 4 millions. Since they will not easily go out of vascular compartment, they are used for intravenous infusion as plasma volume expander for treatment of hypovolemic shock. It may be noted that dextrans are different from previously described dextrins (Box 6.5).

Box 6.4. Inulin and Insulin are Different

| Inulin | is a polysaccharide (carbohydrate) made up of fructose units. It is used for renal function studies. |
| Insulin | is a polypeptide (protein) hormone, with wide ranging actions on carbohydrate and lipid metabolism. |

Box 6.5. Dextrose, Dextrin and Dextran are different

D-glucose is otherwise called Dextrose, a term often used in bed-side medicine, e.g. dextrose drip. Dextrin is the partially digested product of starch. Dextran is high molecular weight carbohydrate, synthesized by bacteria.
Chapter 6; Chemistry of Carbohydrates

**MUCOPOLYSACCHARIDES**

Mucopolysaccharides or glycosaminoglycans (GAG) are heteropolysaccharides, containing uronic acid and amino sugars. Acetylated amino groups, sulfate and carboxyl groups are also generally present. Because of the presence of these charged groups, they attract water molecules and so they produce viscous solutions. Mucopolysaccharides in combination with proteins form mucoproteins. Examples of mucopolysaccharides are hyaluronic acid, heparin, chondroitin sulfate, dermatan sulfate and keratan sulfate.

1. **Hyaluronic Acid**

   It is present in connective tissues, tendons, synovial fluid and vitreous humor. It serves as a lubricant in joint cavities. It is composed of repeating units of N-Acetyl-glucosamine $\rightarrow$ beta-1, 4-Glucuronic acid $\rightarrow$ beta-1, 3-N-Acetyl glucosamine and so on.

2. **Heparin**

   i. It is an anticoagulant widely used when taking blood *in vitro* for clinical studies. It is also used *in vivo* in suspected thrombo-embolic conditions to prevent intravascular coagulation. It activates antithrombin III, which in turn inactivates thrombin, factor X and factor IX.

   ii. Heparin is present in liver, lungs, spleen and monocytes. Commercial preparation of heparin is from animal lung tissues.

   iii. It contains repeating units of sulphated glucosamine $\rightarrow$ alpha-1, 4-L-iduronic acid $\rightarrow$ and so on. (Fig. 6.24). Idose is the 5th epimer of glucose. Iduronic acid is the oxidized form of idose. Sulphated heparin or heparan sulfate is also present in tissues.

3. **Chondroitin Sulphate**

   It is present in ground substance of connective tissues widely distributed in cartilage, bone, tendons, cornea and skin. It is composed of repeating units of glucuronic acid $\rightarrow$ beta-1,3-N-acetyl galactosamine sulphate $\rightarrow$ beta-1, 4 and so on (Fig. 6.25).

4. **Keratan Sulphate**

   It is the only GAG which does not contain any uronic acid. The repeating units are galactose and N-acetyl glucosamine in beta linkage. It is found in cornea and tendons.

5. **Dermatan Sulphate**: It contains L-iduronic acid and N-acetyl galactosamine in beta -1, 3 linkages. It is found in skin, blood vessels and heart valves. Repeating units in various polysaccharides are summarized in Box 6.6.

GLYCOPROTEINS AND MUCOPROTEINS

i. When the carbohydrate chains are attached to a polypeptide chain, it is called a proteoglycan. If the carbohydrate content is less than 10%, it is generally named as a glycoprotein. If the carbohydrate content is more than 10%, it is a mucoprotein. (But some authors use these words as synonyms).

ii. They are seen in almost all tissues and cell membranes. About 5% of the weight of the cell membrane is carbohydrates; the carbohydrate groups cover the entire surface of the cell membrane, they are called glycocalyx. Functions include their role as enzymes, hormones, transport proteins, structural proteins and receptors.

iii. Glycophorin is the major membrane glycoprotein of erythrocytes. It is a transmembrane (spans the whole thickness of the membrane) protein. Carbohydrate chains are attached to the amino terminal portion, outside the cell surface.

iv. The oligosaccharide chains of glycoproteins are composed of varying numbers of the following carbohydrate residues: Glucose (Glu); mannose (Man); galactose (Gal); N-acetyl glucosamine (GluNAc); N-acetyl galactosamine (GalNAc); arabinose (Ara); Xylose (Xyl); L-fucose (Fuc) (Fig. 6.17) and N-acetyl neuraminic acid (NANA). Glycoprotein metabolism is further elaborated in Chapter 10.

Bacterial Cell Wall
Major constituents of prokaryotic (bacterial) cells are heteropolysaccharides, consisting of repeating units of N-acetyl muramic acid (NAM) and N-acetyl glucosamine (NAG). This polysaccharide provides mechanical strength. Synthesis of this complex polysaccharide is blocked by penicillin. This inhibition is responsible for the bactericidal action of penicillin. Penicillin was discovered by Sir Alexander Fleming in 1928. Later, Ernst Chain isolated and purified penicillin. The first clinical trial with penicillin was conducted by Howard Florey in 1940. All the three were awarded Nobel prize in 1945.

Aquasomes
They are one of the most recently developed delivery systems that are making a niche as the peptide/protein carriers. These are nanoparticulate carrier systems with three layered self-assembled structures. They comprise the central solid nanocrystalline core coated with polyhydroxy oligomers onto which biochemically active molecules are adsorbed. The solid core provides the structural stability. The carbohydrate coating acts as dehydroprotectant and stabilizes the biochemically active molecules. As the conformational integrity of bioactive molecules are maintained, aquasomes are being proposed as a carrier system for delivery of peptide based pharmaceuticals. The delivery system has been successfully utilized for the delivery of insulin, hemoglobin and various antigens. Oral delivery of enzymes like serratiopeptidase has also been achieved.

Glycome and Glycomics
Glycomics is the study of structure and function of glycome. The glycome is the total complement of all the carbohydrates in an organism.
Lipids constitute a heterogeneous group of compounds of biochemical importance. Lipids may be defined as compounds which are relatively insoluble in water, but freely soluble in nonpolar organic solvents like benzene, chloroform, ether, hot alcohol, acetone, etc. The functions of lipids are summarized in Box 7.1. The clinical applications are shown in Box 7.2.

CLASSIFICATION OF LIPIDS
Detailed classification is shown in Table 7.1. Based on the chemical nature, lipids are classified as

**Box 7.1. Functions of Lipids**

1. Storage form of energy (triglycerides)
2. Structural components of biomembranes (phospholipids and cholesterol)
3. Metabolic regulators (steroid hormones and prostaglandins)
4. Act as surfactants, detergents and emulsifying agents (amphipathic lipids)
5. Act as electric insulators in neurons
6. Provide insulation against changes in external temperature (subcutaneous fat)
7. Give shape and contour to the body
8. Protect internal organs by providing a cushioning effect (pads of fat)
9. Help in absorption of fat soluble vitamins (A, D, E and K)
10. Improve taste and palatability of food.

**FATTY ACIDS**
Fatty acids, are included in the group of derived lipids. It is the most common component of lipids in the body. They are generally found in ester linkage in different classes of lipids. In the human body free fatty acids are formed only during metabolism.

Fatty acids are **aliphatic carboxylic acids** and have the general formula, $R—CO—OH$, where COOH (carboxylic group) represents the functional group. Depending on the R group (the hydrocarbon chain), the physical properties of fatty acids may vary. Characteristics of common fatty acids are shown in Table 7.2. Classification of fatty acid is given in Table 7.3

**Box 7.2. Clinical Applications**

1. Excessive fat deposits cause obesity. Truncal obesity is a risk factor for heart attack.
2. Abnormality in cholesterol and lipoprotein metabolism leads to atherosclerosis and cardiovascular diseases (Chapter 25).
3. In diabetes mellitus, the metabolisms of fatty acids and lipoproteins are deranged, leading to ketosis (Chapter 24).
Table 7.1. Classification of lipids

I. Simple Lipids
   a. Triacyl glycerol or Triglycerides or neutral fat
   b. Waxes

II. Compound Lipids
   A) Phospholipids, containing phosphoric acid.
      1. Nitrogen containing glycerophosphatides:
         i. Lecithin (phosphatidyl choline)
         ii. Cephalin (phosphatidyl ethanolamine)
         iii. Phosphatidyl serine
      2. Non-nitrogen glycerophosphatides
         i. Phosphatidyl inositol
         ii. Phosphatidyl glycerol
         iii. Diphosphatidyl glycerol (cardiolipin)
   3. Plasmalogens, having long chain alcohol
      i. Choline plasmalogen
      ii. Ethanolamine plasmalogen
   4. Phospho sphingosides, with sphingosine
      Sphingomyelin

B) Non-phosphorylated lipids
   1. Glycosphingolipids (carbohydrate)
      i. Cerebrosides (ceramide monohexosides)
      ii. Globosides (ceramide oligosaccharides)
      iii. Gangliosides (ceramide + oligosaccharides + N-acetyl neuraminic acid)
   2. Sulpholipids or sulfatides
      i. Sulphated cerebrosides
      ii. Sulphated globosides
      iii. Sulphated gangliosides

III. Derived Lipids
Fatty acids, steroids (chapter 12), prostaglandins (chapter 13), leukotrienes, terpenes, dolichols, etc.

IV. Lipids Complexed to Other Compounds
Proteolipids and lipoproteins.

SATURATED FATTY ACIDS
Swedish scientist Scheele isolated glycerol in 1779. Chevreul ME isolated oleic, stearic, butyric and caproic acids in 1823. In 1898, Edmed FG identified the structure of oleic acid. Linoleic acid was prepared from linseed oil by Sacc F in 1844. Lauric acid (12:0) was discovered in Lauraceae seeds by Marsson T in 1849. Franz Soxhlet, a German chemist, invented the Soxhlet apparatus in 1879. This apparatus was used first to separate fats from food.

i. They have the general formula CH₃(CH₂)n-COOH. For example,
   Acetic acid CH₃—COOH
   Butyric acid CH₃(CH₂)₂—COOH
   Palmitic acid CH₃—(CH₂)₁₄—COOH
   Stearic acid CH₃—(CH₂)₁₆—COOH
   Some of the common saturated fatty acids are noted in Table 7.2.
ii. They are named by adding the suffix ‘anoic’ after the hydrocarbon.
iii. The two carbon acetic acid and 4 carbon butyric acid are important metabolic intermediates.
iv. The C\textsubscript{16} (palmitic acid) and C\textsubscript{18} (stearic acid) are most abundant in body fat.

v. Each animal species will have characteristic pattern of fatty acid composition. Thus human body fat contains 50% oleic acid, 25% palmitic acid 10% linoleic and 5% stearic acid.

vi. The carbon atoms of fatty acids are numbered as C1, C2, etc starting from the COOH group. Or, starting from the methyl end, the carbon atoms may be numbered as omega (ω)-1,2,3, etc.

\[
\begin{align*}
\text{CH}_3 &- (\text{CH}_2)_7 - \text{CH} - (\text{CH}_2)_7 - \text{CH} - (\text{CH}_2)_7 - \text{COOH} \\
& \omega_1 \omega_2 \omega_3 \omega_4 \omega_5
\end{align*}
\]

**UNSATURATED FATTY ACIDS**

They are named by adding the suffix ‘enoic’ after the systematic name. They are similar to saturated fatty acids in the reaction of the carboxylic group but also show properties due to presence of the double bond.

Unsaturated fatty acids exhibit geometrical isomerism at the double bonds (Fig. 7.1). All the naturally occurring fatty acids have the cis-configuration. However, in the body during metabolism trans fatty acids are formed (Chapter 13).

The polyunsaturated fatty acids (PUFA) exist in cis-configuration in naturally occurring lipids. Clinical significance of PUFA is shown in Box 7.3.
Many clinical and epidemiologic studies have shown positive roles for omega-3 fatty acids in infant development; cancer; cardiovascular diseases; and more recently, in various mental illnesses, including depression, attention-deficit hyperactivity disorder, and dementia. These fatty acids are known to have pleiotropic effects, including effects against inflammation, platelet aggregation, hypertension, and hyperlipidemia. These beneficial effects may be mediated through several distinct mechanisms, including alterations in cell membrane composition and function, gene expression, or eicosanoid production.

Trans Fatty Acids (TFA)
They are present in dairy products and in hydrogenated edible oils. They are generally considered to be injurious to health. However, they are used in food industry as they increase the shelf life of the fried food. Oils containing PUFA also have high content of TFA. Fast food preparations have a high TFA content. Trans fatty acids adversely affect multiple risk factors, including plasma lipids and lipoproteins, systemic inflammation, endothelial dysfunction, insulin resistance, diabetes and adiposity. It is high in processed foods and bakery products, where partially hydrogenated vegetable oils are used for cooking.

Properties of Fatty Acids
The composition of some of the common oils and fats are given in Table 7.4.

( *) these saturated fatty acids are medium chain fatty acids.
( **) contains erucic acid, 22 C, 1 double bond

1. Hydrogenation
Unsaturated fatty acids may be converted to the corresponding saturated fatty acids by hydrogenation of the double bond.

\[
\text{Linolenic} \rightarrow \text{Linoleic} \rightarrow \text{Oleic} \rightarrow \text{Stearic}
\]

Hydrogenation of oils can lead to solidification and saturation, e.g. Vanaspathi.

2. Halogenation
When treated with halogens under mild conditions, the unsaturated fatty acids can take up two halogen atoms, at each double bond to form the halogenated derivative of the fatty acid. For example,

\[
\text{Oleic} + I_2 \rightarrow \text{Di-iodo oleic acid}
\]

The number of halogen atoms taken up will depend on the number of double bonds and is an index of the degree of unsaturation. (See iodine number, under triglycerides).

3. Melting Point
The short and medium chain fatty acids are liquids, whereas long chain fatty acids are solids at 25°C. The solubility in water decreases, while melting and boiling points increase, with increase in chain length.

The unsaturated fatty acids have lower melting point compared to saturated fatty acids with the
same chain length. For example, stearic acid (C18 fatty acid, no double bond) has the melting point 69°C, oleic acid (C18, 1 double bond) has 13°C; linoleic acid (C18, 2 double bonds) has –5°C and linolenic (C18, 3 double bonds) has –10°C.

4. Salt Formation
Saturated and unsaturated fatty acids form salts with alkali.

\[ \text{CH}_3\text{—COOH} + \text{NaOH} \rightarrow \text{CH}_3\text{—COONa} + \text{H}_2\text{O} \]

Sodium and potassium salts of long chain fatty acids are called soaps. Calcium and magnesium soaps are insoluble. Calcium soaps are used in grease.

Alkyl sulfate (R—CH₂—O—SO₂—ONa) and alkyl sulfonate (R—CH₂—SO₂—O—Na) are not precipitated by hard water and are used as detergents.

5. Ester Formation
Both saturated and unsaturated fatty acids form esters with alcohols, especially with glycerol. Fatty acids can form mono-, di- or tri-esters with alcohol groups of glycerol. Triglycerides or triacyl glycerols are also known as neutral fat (Fig. 7.3).

Glycerol + fatty acid \( \rightarrow \) Mono acyl glycerol
Monoglyceride + fatty acid \( \rightarrow \) Di acyl glycerol
Diglyceride + fatty acid \( \rightarrow \) Triglyceride or tri acyl glycerol

6. Oxidation of Fatty Acids
All fatty acids undergo oxidation in the body to give energy. Beta-oxidation is the major process by which acids are oxidized (Chapter 11). However, the unsaturated fatty acids can undergo auto oxidation, due to the presence of the highly reactive double bonds and a variety of products.

**NEUTRAL FATS**
Neutral fats are also called as triacylglycerols (TAG) or triglycerides (TG). These are esters of the trihydric alcohol, glycerol with fatty acids (Fig. 7.3).

1. Nomenclature of Carbon Atoms
As per International Union of Biochemistry (IUB) the correct designations are monoacyl glycerol, diacyl glycerol and triacyl glycerol. But the old terminology of monoglyceride, diglyceride and triglyceride are still popular, especially among clinical laboratory workers.

The carbon atoms of glycerol are designated as \( \alpha, \beta \) and \( \alpha' \) or as 1, 2, 3 as shown in the Figure 7.3, where \( R \) represents the side chain of fatty acids. Enzymes can distinguish between 1st and 3rd carbon atoms.

2. Mixed Triglycerides
   i. Naturally occurring fats and oils are mixtures of triglycerides.
   ii. If all the three hydroxyl groups of the glycerol are esterified to the same fatty acid, a simple triacyl glycerol is formed, e.g. Tripalmitin, Triolein, etc.
   iii. A mixed triglyceride is formed, when different fatty acids are esterified to the hydroxyl groups of glycerol.
   iv. Generally two hydroxyl groups are esterified to similar fatty acid and the third with a different one, e.g. 1, 3-dipalmitoyl-2-olein; 1-palmitoyl-2, 3-distearin, etc. When a PUFA is present, it is commonly esterified to the 2nd or \( \beta \) carbon atom.

3. Physical Properties of Triacylglycerols
   i. They are hydrophobic and insoluble in water.
   ii. Oils are liquids at 20°C; they are triglycerides which contain a higher proportion of unsaturated fatty acids or short chain triglycerides. Oils are generally of plant origin.
   iii. Fats are solids at room temperature and contain mainly saturated long chain fatty acids. Fats are mainly of animal origin (Table 7.4).
   iv. When the constituent fatty acids have a higher chain length and are predominantly saturated, ‘hard fat’ is formed, e.g. pig fat.
   v. Fats containing medium chain triglycerides or unsaturated fatty acids are soft fats, e.g. butter, coconut oil. Coconut oil contains mainly medium chain TAG, e.g. Lauric and Myristic acids.

4. Storage of Energy as Fat
The triacylglycerols are the storage form of lipids in the adipose tissue. In a 70 kg normal person, body stores contain about 11 kg of triacyl
glycerol, which is roughly equivalent to 100,000 kCal. If the same calories were stored as hydrated glycogen, the total weight of this alone would have been 65 kg. When stored as TAG, water molecules are repelled and space requirement is minimal. Excess fat in the body leads to obesity.

5. Hydrolysis of Triglycerides
This occurs in the body during digestion of dietary fat and mobilization of TAG from adipose tissue. Triglycerides in the body are hydrolysed by enzymes, lipases which are hydrolases (class 3 enzymes, Chapter 5). Triacyl glycerol is sequentially hydrolysed to diacyl glycerol and mono acyl glycerol and finally glycerol plus 3 fatty acids (Fig. 7.4).

6. Saponification
i. When triglycerides are hydrolysed by alkali, the process is known as saponification. The products are glycerol and soaps (Fig. 7.5).

ii. Saponification number is defined as the number of milligrams of potassium hydroxide required to saponify one gram of fat.

iii. It is an indication of the molecular weight of the fat, and is inversely proportional to it. Human fat has a saponification number of 194-198, butter has 210-230 and coconut oil has 253-262.

7. Iodine Number
Iodine number of a fat is defined as the number of grams of iodine taken up by 100 grams of fat. It is an index of the degree of unsaturation and is directly proportional to the content of unsaturated fatty acids. Higher the iodine number, higher is the degree of unsaturation, e.g. iodine number of butter is 28, and that of sunflower oil is 130.

8. Rancidity of Fat
Fats and oils have a tendency to become rancid. The term rancidity refers to the appearance of an unpleasant smell and taste for fats and oils.

Hydrolytic rancidity is due to partial hydrolysis of the triacyl glycerol molecules due to traces of hydrolytic enzymes present in naturally occurring fats and oils.

Oxidative rancidity is the result of partial oxidation of unsaturated fatty acids with resultant formation of epoxides and peroxides of small molecular weight fatty acids by peroxides and free radicals. The same process, if it occurs in vivo will affect the integrity of biomembranes, leading to cell death.

Many natural fats and oils may contain antioxidants (e.g. vitamin E), which prevent the occurrence of oxidative rancidity. PUFA are more easily oxidized; so vegetable oils with a high content of PUFA are usually preserved with addition of antioxidants.

Repeated heating of oils would lead to the formation and polymerisation of cyclic hydrocarbons. These will impart an unpleasant taste and color to the oil. Coconut oil having medium chain saturated fatty acids will withstand such polymerisation.

Waxes
They form the secretions of insects, leaves and fruits of plants, e.g. Lanolin or wool fat, beeswax, whalesperm oil, etc. They are esters of higher fatty acids with higher monohydroxy aliphatic alcohols and so have very long straight chains of 60-100 carbon atoms. They are used as the base for the preparation of cosmetics, ointments, polishes, lubricants and candles.
PHOSPHOLIPIDS
They contain glycerol, fatty acids and a nitrogenous base. Lecithin, was discovered in 1870 by the German biochemist Ernst Hoppe-Selyer. Strecker characterized choline in 1861. In 1884, Thudichum JLW described sphingosine, sphingomyelin, cerebrosides, cephalin and lecithin in brain tissue.

A. Phosphatidates
i. These are derivatives of phosphatidic acid which is the simplest phospholipid.
ii. Phosphatidic acid is made up of one glycerol to which two fatty acid residues are esterified to carbon atoms 1 and 2. The 3rd hydroxyl group is esterified to a phosphoric acid (Fig. 7.6).
iii. The molecule has an asymmetric carbon atom and therefore, exhibits optical isomerism. L-isomer is found in nature.

B. Amphipathic Nature
Phospholipids in general are amphipathic, particularly Lecithin. They have both hydrophobic and hydrophilic portion in their molecule (Figs 7.7A and 7.8). The glycerol along with the phosphoric acid and choline constitute the polar 'head' of a phospholipid molecule, whereas the hydrocarbon chains of the fatty acids represent the nonpolar 'tail'.

C. Micellar Formation
When phospholipids are distributed in water, their hydrophobic parts keep away from water, forming molecular aggregates called micelle (Fig.7.7B). These are involved in solubilization of lipids in aqueous media and help in digestion and absorption of lipids.

D. Liposomes
A lipid bilayer will close on itself under appropriate conditions to form liposomes. Unilamellar or multilamellar liposomes may be formed. They may be prepared by sonication of mixtures of phospholipids and cholesterol (Fig.7.7B). Liposomes are microscopic spherical vesicles. When mixed in water under special conditions, the phospholipids arrange themselves to form a bilayer membrane which encloses some of the water in a phospholipid sphere. Drugs, proteins, enzymes, genes, etc. may be encapsulated by the liposomes which could act as carriers for these substances to target organs. Liposome-entrapped drugs exhibit superior pharmacological properties than those observed with conventional formulations. Liposomes have important applications in cancer chemotherapy, antimicrobial therapy, gene therapy, vaccines and diagnostic imaging.

E. Biomembranes
The molecules align themselves to form monolayers with the polar heads pointing in one direction and the nonpolar tails in the opposite direction (Figs 7.7A and B). Only fatty acids with more than 6 carbon atoms form monolayers. This explains their role as components of biomembranes The self-assembly of phospholipids into bilayers is driven by hydrophobic interaction. They also act as detergents and emulsifying agents. In vivo, they act as pulmonary surfactants.
1. Phosphatidyl choline or Lecithin

i. This is a nitrogen containing phospholipid. The word lecithin is derived from the Greek word, lekithos = egg yolk. It contains glycerol.

ii. The alpha and beta positions are esterified with fatty acids. Usually the fatty acid attached to the beta-carbon is a PUFA molecule (Fig.7.8).

iii. The phosphoric acid is added to the third position, to form phosphatidic acid. The phosphate group is esterified to the quaternary nitrogen base, Choline (Fig.7.8). The molecules of lecithin exist as zwitterions (pI = 6.7).

**Action of Phospholipases**

Phospholipases are enzymes that hydrolyse phospholipids. Different phospholipases are involved in the hydrolysis of specific bonds in lecithin (Fig. 7.8). Phospholipase A2 acts on an intact lecithin molecule hydrolysing the fatty acid esterified to the beta (second) carbon atom. The products are Lysolecithin and fatty acid. Lysolecithin is a detergent and hemolytic agent. The enzyme is present in the venom of viper snakes. The hemolysis and consequent renal failure seen in viper poisoning could be thus explained. Actions of other phospholipases are shown in Figure 7.8. The products formed in each case may be summarized as follows:

![Phospholipase A2](image)

**Lung Surfactants**

Normal lung function depends on a constant supply of lung surfactants. It is produced by epithelial cells. It decreases surface tension of the aqueous layer of lung and prevents collapse of lung alveoli. Constituents of surfactants are dipalmitoyl lecithin, phosphatidyl glycerol, cholesterol and surfactant proteins A, B and C. During fetal life, the lung synthesizes sphingomyelin before 28th week of gestation. But as fetus matures, more lecithin is synthesized. The lecithin-sphingomyelin (LS) ratio of amniotic fluid is an index of fetal maturity. A ratio of 2 indicates full lung maturity. Low levels of surfactant leads to respiratory distress syndrome (RDS), which is a common cause of neonatal morbidity.

**Respiratory Distress Syndrome (RDS)**

It is due to a defect in the biosynthesis of dipalmitoyl lecithin (DPL), the main pulmonary surfactant. Premature infants have a higher incidence of RDS because the immature lungs do not synthesize enough DPL.

2. Phosphatidyl ethanolamine or Cephalin

Cephalin differs from lecithin in that the nitrogen base ethanolamine is present instead of choline (Fig.7.9). Cephalin is also found in biomembranes and possesses amphipathic properties.

3. Phosphatidyl inositol

Here phosphatidic acid is esterified to inositol (Fig. 7.10). Phosphatidyl inositol bisphosphate or PIP2

![Phosphatidyl Inositol](image)
is present in biomembranes. This compound plays a vital role in the mediation of hormone action on biomembranes and acts as a second messenger (see Chapter 44).

4. Plasmalogens
These are phospholipids which have an aliphatic long chain $\alpha - \beta$ unsaturated alcohol in ether linkage with the first hydroxyl group of glycerol (Fig.7.11). The second OH group is esterified to a fatty acid. The phosphoric acid is attached to choline or ethanolamine (Fig. 7.11). The alcohols have about C12 to C18 chain length. Plasmalogens are found in biomembranes in brain and muscle.

5. Phosphatidyl Glycerol
It is formed by esterification of phosphatidic acid to glycerol. When two molecules of phosphatidic acid are linked with a molecule of glycerol, diphosphatidyl glycerol or cardiolipin is formed. It is the major lipid of mitochondrial membrane. Commercially, it is extracted from myocardium. Decreased cardiolipin level leads to mitochondrial dysfunction, and is accounted for heart failure, hypothyroidism and some types of myopathies.

6. Sphingolipids
The sphingosine containing lipids may be of 3 types; phosphosphingosides, glycosphingolipids and sulfatides. All sphingolipids have the long aliphatic amino alcohol sphingosine (Fig.7.12) which is attached to a fatty acid in amide linkage to form a ceramide (Fig.7.13). The fatty acid has a chain length varying from C18 to C24.

7. Phosphosphingosides
They contain phosphoric acid group. A common phosphosphingoside present abundantly in biomembranes, especially of the nervous system, is sphingomyelin. It contains choline (Fig.7.14).

Sphingomyelins
Sphingomyelins are the only sphingolipid that contain phosphate and have no sugar moiety. They are found in large quantities in nervous system. Different sphingomyelins may be formed depending on the fatty acid attached. Common fatty acids found are—lignoceric (24 C), nervonic (24 C, one double bond) and cervonic (22 C, 6 double bonds) acids (Table 7.2). Because of its amphipathic nature sphingomyelin can act as an emulsifying agent and detergent. The relative proportion of lecithin and sphingomyelin is important in biological fluids like bile, amniotic fluid, etc. Sphingomyelin combined with fatty acid is called ceramide, which is a component of glycosphingolipids.

Non-phosphorylated Lipids
Glycosphingolipids (Glycolipids)
They are seen widely in nervous tissues. This group of lipids do not contain phosphoric acid; instead they contain carbohydrates and ceramide.
Ceramide + Glucose → Gluco cerebroside  
Ceramide + Galactose → Galacto cerebroside

**Globosides (Ceramide oligosaccharides)**  
They contain two or more hexoses or hexosamines, attached to a ceramide molecule.

Ceramide + Galactose + Glucose  
→ Lactosyl ceramide

Lactosyl ceramide is a component of erythrocyte membrane.

**Gangliosides**  
They are formed when ceramide oligo-saccharides have at least one molecule of NANA (N-acetyl neuraminic acid) (sialic acid) attached to them.

Ceramide—Glucose—galactose—NANA;  
this is designated as GM3 (ganglioside M3).

Gangliosides contribute to stability of paranodal junctions and ion channel clusters in myelinated nerve fibers. Autoantibodies to GM1 disrupt lipid rafts, paranodal or nodal structures, and ion channel clusters in peripheral motor nerves.

**Sulfolipids or Sulfatides**  
These are formed when sulfate groups are attached to ceramide oligosaccharides. All these complex lipids are important components of membranes of nervous tissue. Failure of degradation of these compounds results in accumulation of these complex lipids in CNS. This group of inborn errors is known as **lipid storage diseases**. These are described in Chapter 13.

**Lipidomics**  
The lipidome is the total lipids in the organism. Lipidomics is the study of the structure and function of all members of the lipidome, in both health and in diseases.

**Related Topics**  
Cholesterol, steroids, bile acids and lipoproteins are described in Chapter 12. Chapter 13 contains the metabolism of compound lipids.
By utilizing mutant strains of bacteria, metabolic defects may be elucidated.

**Level 2: Organ Perfusion**

The organ can be isolated preserving its blood vessels. The organ is canulated and perfused with Ringer solution. To the perfusion fluid any compound may be added and the fluid emerging from the organ is analyzed for the metabolites of the compound.

**Level 3: Organ Slices**

The next lower level of study is by using the slices of organs, about 50 micrometer thick. Otto Warburg (Nobel prize 1931) was the first scientist to study metabolic pathways using organ slices. (The instrument for study of tissue respiration is known as Warburg apparatus). The advantage of this procedure is that the cellular organelle were preserved intact. Metabolic transformations of nutrients could be studied in detail. If rat liver slices are incubated with medium containing glucose, carbon dioxide is evolved.

**Level 4: Intact Cells and Tissue Culture set up**

Tissues or cells can be kept in defined culture medium for a few days for metabolic studies. The medium contains nucleotides, carbohydrates, amino acids, vitamins and growth factors. The pH of the medium should be kept around 7.2. If labelled glucose is added in the culture, the utilization of glucose and its incorporation into glycogen, etc. could be identified. If labelled nucleotides are added in the culture, cells take them up for DNA synthesis and the uptake of radioactivity will be proportional to the cell division. Activities of drugs can be studied in cell culture system. Biologically useful substances can be harvested from tissue culture set up. For example, specific monoclonal antibodies could be obtained from the supernatant of cultured hybridoma cells (Chapter 49).
The cells from cancer tissues have indefinite capacity to grow into any number of passages. This **immortalization** is characteristic of cancer tissues. A good example is the HeLa cell line from cervical cancer tissue, now growing in laboratories all over the world. This cell line was originally started in 1938 from a patient, Henrietta Lacks whose first and last names were abbreviated to name the culture. A pioneer in tissue culture work was Alexis Carrel (Nobel prize, 1912).

**Level 5: Homogenates**

The tissue is homogenized in an isotonic medium and cell wall is broken by ultrasonic vibration and cellular organelle are separated. For example, isolated mitochondrial preparation will show enzymes of electron transport chain.

**Level 6-A: Purified Enzymes**

Enzyme preparations may be used to study individual metabolic reactions, their regulation, cofactors, etc.

**Level 6-B: DNA or Genomics**

Present day research work mainly involves, the studies at genetic level (molecular biology). For example, phenyl ketonuria is due to a mutation in the gene coding for the enzyme phenyl alanine hydroxylase. The full complement of genes within the cells (genomics), their expression and regulation (transcriptomics) and the gene products (proteomics) can be studied.

**Use of Radioisotope Tracers**

The isotope studies provide valuable information regarding precursor–product relationship, rate of metabolism and anatomical distribution (Chapter 53). When $^{14}\text{C}$-labelled glucose is administered, the metabolites can be traced to different organs. Administration of $^{15}\text{N}$-labelled glycine was followed by appearance of the label in different compounds like hemoproteins, nucleic acids, and creatinine.

**Studies on Metabolism**

Four aspects of metabolic pathways are studied

a. Sequence of reactions  
b. Precursor product relationship  
c. Mechanism of reaction  
d. Control mechanisms

Metabolic pathways may also be studied by creating perturbances to the system, such as:

a. By causing metabolic blocks  
b. By studying organisms with metabolic defects  
c. Genetic manipulation, e.g. gene knockout (details in Chapter 55).

**METABOLISM**

Thousands of chemical reactions are taking place inside a cell in an organized, well co-ordinated, and purposeful manner; all these reactions are collectively called as **Metabolism**. The metabolism serves the following purposes:

1. Chemical energy is obtained from the degradation of energy rich nutrients.
2. Food materials are converted into the building block precursors of cellular macromolecules. These building blocks are later made into macromolecules, such as proteins, nucleic acids, polysaccharides, etc. Biomolecules required for specialized functions of the cell are synthesized.
3. Metabolic pathways are taking place with the help of sequential enzyme systems. These pathways are regulated at three levels:
   3a. Regulation through the action of allosteric enzymes, which increase or decrease the activity under the influence of effector molecules.
   3b. Hormonal regulation. Hormones are chemical messengers secreted by different endocrine glands.
   3c. Regulation at the DNA level; the concentration of the enzyme is changed by regulation at the level of synthesis of the enzyme.

**Types of Metabolic Pathways**

A. **Catabolic** (degradation) pathways, where energy rich complex macromolecules are degraded into smaller molecules. Energy released during this process is trapped as chemical energy, usually as ATP.

B. Anabolic (biosynthesis) pathways. The cells synthesize complex molecules from simple precursors. This needs energy.

C. Amphibolic pathways are seen at crossroads of metabolism, where both anabolic and catabolic pathways are linked.

Stages or Phases of Metabolism

The degradation of foodstuffs occurs in three stages.

i. In the first stage, digestion in the gastrointestinal tract converts the macromolecules into small units. For example, proteins are digested to amino acids. This is called primary metabolism.

ii. Then these products are absorbed, catabolized to smaller components, and ultimately oxidized to CO2. The reducing equivalents are mainly generated in the mitochondria by the final common oxidative pathway, citric acid cycle. In this process, NADH or FADH2 are generated. This is called secondary or intermediary metabolism.

iii. Then these reduced equivalents enter into the electron transport chain (ETC, or Respiratory chain), where energy is released. This is the tertiary metabolism or Internal respiration or cellular respiration (see Fig. 19.1).

METABOLIC PROFILE OF ORGANS

The metabolic pattern or metabolic profile of different organs is different depending on its function. Moreover, the organs are able to adapt to metabolic alterations in fed state and starvation. The storage forms of fuels are shown in Table 8.1.

Calories are stored in the body as fat and glycogen. The approximate percentage of storage form of energy (total fuel reserve) present in a normal human body is, fat 85%, glycogen 1%, and proteins 14%. Box 8.1 shows the energy utilization of an average person.

Fat stores are mobilized actively only on prolonged fasting, even though adipose tissue fat is undergoing turnover on a daily basis. Caloric homeostasis is maintained regardless of whether a person is well fed, fasting, or in a state of starvation. Similarly metabolic profile of various organs and tissues change to adapt to physiological and pathological states, so that caloric homeostasis is maintained unless extreme conditions set in.

The reciprocal regulation of glycolysis and gluconeogenesis is the major deciding factor in the flux of metabolic intermediates through these pathways.

1. Brain

i. Although brain represents only 2% of adult body weight, it needs 10–20% cardiac output.

About 750 ml of blood circulates through the brain. The energy consumption varies based on life style in adults. Approximately 300 g of carbohydrates (1200 Kcal or 4800 kJoules), 70 g of proteins (294 Kcal or 1190 kJ) and 80 g of fats (720 kcal or 2960 kJ) are consumed by a person with a sedentary life style. Therefore, about 60% calories are derived from carbohydrates, 15% from proteins and rest from fats. The energy reserves provide energy in between meals and after overnight fasting (glycogenolysis and gluconeogenesis).
brain per minute. Neurons can survive only a few minutes without blood supply. Occlusion of blood supply to brain causes unconsciousness within 10 seconds.

ii. There is no stored fuel in the brain. Glucose, the preferred fuel for the brain, should be in continuous supply. Glucose can freely enter the brain cells.

iii. The total consumption of glucose by brain is about 120 g/day (480 kcal). Thus, about 60% of the total carbohydrate intake by the body is metabolized by the brain. Moreover, about 25% of the oxygen consumed by the adult body is due to glucose oxidation in brain. In children, this may be as high as 50%.

iv. Brain under conditions of anoxia: In anoxia the rate of lactate production by glycolysis rises to 5 or 8 times within one minute. The Pasteur effect (Chapter 9) is the brain's protection against conditions of anoxia. Blood glucose level below 30 mg/dl is fatal.

v. Brain and acetoacetate: The brain is unable to utilize fatty acids as a source of fuel since the fatty acids complexed to albumin are unable to traverse the blood brain barrier. But, brain can effectively utilize acetoacetate. This is again a survival technique in diabetic and starvation ketosis.

vi. Brain and starvation: During starvation, a significant part (60-70%) of the energy requirement of the brain is then met by ketone bodies (Fig. 8.1).

vii. Under conditions of partial anoxia, the production of ammonia is increased. This is immediately trapped as glutamine. The NH$_2$ group of glutamine and glutamate can be used for synthesis of other amino acids (Chapter 16).

2. Skeletal Muscle

i. The skeletal muscle forms about 45% of the total weight of the body. About 0.5% muscle weight is due to glycogen content. Following a meal, the muscle glycogen content increases by about 1% of the total weight.

ii. Muscle metabolism after a meal: The uptake and storage of glucose by the skeletal muscle is under the influence of insulin. Following a

**Fig. 8.3. Metabolism in fasting state**
meal, the level of the glucose and insulin are high. So glycogen synthesis is enhanced (Fig. 8.2). The resting muscle uses fatty acids as a major fuel (85%).

iii. Muscle metabolism during exercise: Muscle uses glycogen for short active spurts of activity. Glycogen is rapidly broken down to form lactate. The lactate has to be transported to liver to undergo gluconeogenesis (Cori’s cycle in Chapter 9). Muscle however uses fatty acid as fuel for aerobic exercise and long distance running.

iv. Muscle metabolism during starvation: During starvation, maximum glucose is spared for the brain. The free fatty acid (FFA) mobilized from adipose tissue is the preferred fuel for muscle during starvation. FFA does not require insulin, and during fasting insulin level is low (Table 8.3).

v. During prolonged starvation, muscle protein breakdown occurs and alanine is released to the blood stream. It is transported to liver to provide substrate for gluconeogenesis (glucose-alanine cycle in Fig. 9.30). The metabolic fuel during prolonged fasting is ketone bodies. Branched chain amino acids are utilized by the skeletal muscle (Fig. 8.3 and Table 8.2).

3. Adipose Tissue
It is the storehouse of energy in the body (about 1,35,000 kcal) (Table 8.1). The energy is stored in the concentrated form, triacyl glycerol. The chylomicrons and VLDL are hydrolysed by lipoprotein lipase present on capillary walls. It is activated by insulin. The fatty acids are re-esterified to form triacyl glycerol (Chapter 11). The glycerol is derived from dihydroxy acetone phosphate (DHAP), an intermediate of glycolysis. Therefore, for storage of triacyl glycerol, both fatty acid synthesis and glycolysis should operate. The uptake of glucose, glycolysis and lipogenesis are all favored by insulin.

About 25% of glucose taken up by adipose tissue is metabolized by the HMP shunt pathway, and the rest by glycolysis. The NADPH generated from the shunt pathway is used for the synthesis of fatty acids. The NADH produced during glycolysis is used to reduce the DHAP to glyceral-3-phosphate. Table 8.3 shows the major metabolic fuels of different organs during various physiological conditions.

During fasting, triglycerides in the adipose tissue are hydrolysed. Cyclic AMP mediated activation of hormone sensitive lipase occurs in response to the high glucagon-insulin ratio. Glucocorticoids also have a stimulant lipolytic effect during fasting.

4. Liver
i. The liver plays a central role in metabolism by providing adequate quantities of metabolic fuel for other organs. Almost all the metabolic pathways operate in the liver; a notable exception being ketolysis.

ii. Liver metabolism in fed state: Under well fed conditions, the liver takes up glucose from

circulation and stores it as glycogen. Similarly the fatty acids synthesized by the liver are incorporated into VLDL and secreted into blood stream. (Fig. 8.2). Liver is the major site of degradation of amino acids and detoxification of ammonia into urea (Chapter 14).

iii. During starvation, liver provides glucose by glycogenolysis and later by gluconeogenesis so that the obligatory requirements of the brain are met (Fig. 8.3). Moreover, liver also produces the ketone bodies, an alternate source of fuel. But the liver cannot use ketone bodies as its own fuel. Table 8.3 shows the major metabolic fuels of different organs during various physiological conditions.

5. Cardiac Muscle
Heart consumes more energy than any other organ. It utilizes about 6 kg of ATP per day, 20-30 times of its own weight. Cardiac muscle derives its energy by oxidative metabolism of fatty acids (60-90%) and glucose 10-40%. Ketone bodies are also normally metabolized.

In addition, energy transfer to heart’s myofibrils occurs by creatine kinase catalyzed energy shuttle. Phosphocreatine being a smaller molecule than ATP can easily diffuse into the myofibrils from mitochondria. The myofibrillar creatine kinase catalyses the reformation of ATP. The free creatine diffuses back. The creatine kinase system acts as an energy buffer, by keeping ATP level constant. When ADP level increases due to a fall in phosphocreatine, it inhibits intracellular enzymes causing failure of the heart’s contracting mechanism. In a failing heart, the uptake and utilization of fatty acids and glucose occurs. In advanced heart failure, insulin resistance also develops, further decreasing the glucose utilization. At the same time, the metabolism of a hypertrophied heart switches from fatty acid utilization to glucose.

Table 8.4 shows the activity of key enzymes under well fed conditions, fasting and starvation and their regulators.

**Effect of Exercise on Metabolic Profile**
Long distance running is the typical example of aerobic exercise, where as sprinting or weight lifting exemplifies anaerobic exercise. During anaerobic exercise, the major organ involved is the skeletal muscle with very little involvement of other organs. The relative ischemia created by the compression of blood vessels in the muscle will necessitate the use of glycogen and phosphocreatine available in the muscle to supply the required energy.

During moderate aerobic exercise, the muscular stores of glycogen are used, but in a normal individual this is not sufficient to provide a continuous supply of ATP for exercise like long distance running. The RQ falls during long distance running since there is a progressive change from glycogenolysis to fatty acid oxidation to meet the energy demands. Muscles start oxidizing fatty acids and the high AMP level which activates AMP kinase and low malonyl CoA that activates CAT will favor fatty acid oxidation. The training for athletes is different depending on whether they are sprinters or long distance runners since the energy sources are different. Rest after a vigorous muscular activity often results in repletion of the exhausted glycogen stores.

In muscle developed by exercise and training, the size and number of mitochondria are more as well as the level of enzymes for fatty acid oxidation and ketone body utilization. Hence, the trained muscle can better utilize noncarbohydrate sources of energy. So exhaustion is delayed (Box 8.2).

**Box 8.2. Long Distance Runners do not Compete with Sprinters!!**

Long distance running is an example of aerobic exercise. Metabolic profile of organs changes during aerobic exercise with fatty acids and ketone bodies being the preferred fuel for the skeletal muscle. Because glycogenolysis is not sufficient to meet the energy demands of prolonged aerobic exercise.

Anaerobic exercise, on the other hand, has no effect on the metabolic profile of organs other than skeletal muscle. The skeletal muscle depends on its own glycogen stores and phosphocreatine to meet the demand for ATP.
Metabolic Adaptations During Starvation

In early fasting the effect of short term regulation by altering the activity of existing enzymes (fine control) is more significant. When starvation is prolonged (>3 days), long term adaptation sets in, e.g. brain starts metabolising ketone bodies deriving about 30% energy from ketone bodies.

First Stage: Glycogenolysis

Table 8.2 and Figure 8.3 show the changes in activities during starvation. During fasting, at first, blood glucose level is maintained by hepatic glycogenolysis. The glycogen stores are sufficient for about 18 hours. The primary requirement for glucose is to meet the demands of the brain.

Second Stage: Gluconeogenesis

Even before the glycogen stores are depleted, gluconeogenesis is accelerated (Fig. 8.3). The amino acids released from muscle form the major substrate for gluconeogenesis. The amino nitrogen is transferred from other amino acids to pyruvate to form alanine. Thus the amino group reaches the liver as alanine where it is transaminated to give pyruvate for gluconeogenesis. This glucose alanine cycle (Fig. 9.30) serves to transport the amino nitrogen of other amino acids to liver in a harmless form. Glutamic acid also serves as an important mode of transport of amino acids to liver (Chapter 14).

The branched chain amino acids liberated by muscle protein catabolism especially leucine and isoleucine are utilized by the muscle to give energy. Brain can preferentially take up the glucogenic valine from the blood stream. The plasma level of branched chain amino acids reaches a peak by 5th day of starvation.

Third Stage: Lipolysis

The prevailing state of high glucagon-insulin ratio stimulates cAMP mediated lipolysis by increasing the activity of hormone sensitive lipase. Then skeletal muscle, heart and kidney will shut down their glucose utilization; and will depend mainly on fatty acids for energy needs (glucose-fatty acid-cycle). Inactivation of pyruvate dehydrogenase by phosphorylation is the basis of this change. The stimulation of the activity of CAT by glucagon favors increased rate of beta oxidation. The increased rate of lipolysis and beta oxidation provides an alternate source of fuel as acetyl CoA and subsequently ketone bodies. Ketone bodies provide fuel for tissues like heart muscle, skeletal muscle and to some extent the brain. It is seen that brain starts utilizing ketone bodies from 3rd day of starvation. By 10th day of starvation about 60% of energy for brain is derived from ketone bodies.

Fourth Stage: Acidosis

However, this state cannot continue indefinitely since excessive production of ketone bodies leads to metabolic acidosis. When the bicarbonate buffering capacity is exceeded, the pH falls and hyperventilation occurs as a compensatory mechanism.

Fifth Stage: Death from Starvation

Metabolic acidosis and dehydration, unless corrected efficiently, will lead to death. A normal person has fuel reserves to live up to 45–60 days. Examples are available in history. As part of the freedom struggle, Sri Jatin Das took a fast unto death, who died on the 61st day of his hunger strike on 13th September 1929.
### Major Metabolic Pathways of Glucose

**CHAPTER 9**

**CHAPTER AT A GLANCE**

The reader will be able to answer questions on the following topics:

1. Digestion of carbohydrates
2. Absorption of glucose and glucose transporters
3. Glycolysis pathway and its regulation
4. Energy yield from glycolysis
5. Cori’s cycle
6. Pyruvate as a junction point
7. Gluconeogenesis and Malate shuttle
8. Glucose alanine cycle
9. Glycogenesis; glycogen synthetase
10. Regulation of glycogen metabolism; Cyclic AMP
11. Glycogen storage diseases

---

**DIGESTION OF CARBOHYDRATES**

i. In the diet carbohydrates are present as complex polysaccharides (starch, glycogen), and to a minor extent, as disaccharides (sucrose and lactose). They are hydrolysed to monosaccharide units in the gastrointestinal tract. Cooking makes the digestion process easier.

ii. This process of digestion starts in mouth by the salivary alpha-amylase. However, the time available for digestion in the mouth is limited, because the gastric hydrochloric acid will inhibit the action of salivary amylase.

iii. In the pancreatic juice another alpha-amylase is available which will hydrolyse the alpha-1,4 glycosidic linkages randomly, so as to produce smaller subunits like maltoase, isomaltose, dextrins and branched or unbranched oligosaccharides.

iv. The cells of brush border of intestine contain the enzymes, sucrase, maltase, isomaltase and lactase. They hydrolyse the corresponding disaccharides into component monosaccharides which are then absorbed.

**Clinical Application; Lactase Intolerance**

i. Lactase hydrolyses lactose to glucose and galactose. Lactase is present in the brush border of enterocytes.

---

**Absorption of Glucose**

Glucose has specific transporters, which are transmembrane proteins. Table 9.1 shows a summary of the glucose transporters.

1. **Co-transport from Lumen to Intestinal Cell**
   i. This process is mediated by Sodium Dependent Glucose Transporter-1 (SGluT-1) (Fig. 9.1). Absorption from intestinal lumen into intestinal cell is by co-transport mechanism (secondary active transport) (Chapter 2).

   ii. A membrane bound carrier protein is involved, which carries glucose, along with sodium. This sodium is later expelled by the sodium pump with utilization of energy. So energy is needed indirectly (details in Chapter 2).

   iii. The transporter in intestine is named as SGluT-1 and the transporter in the kidney is called SGluT-2. The first one is involved in glucose-galactose malabsorption. The SGluT-2 is defective in congenital renal glycosuria.

   iv. **Clinical application**: Common treatment for diarrhea is oral rehydration fluid. It contains glucose and sodium. Presence of glucose in...
oral rehydration fluid allows uptake of sodium to replenish body sodium chloride.

2. Another Uniport System Releases Glucose into Blood

i. The same intestinal epithelial cells have a different transport mechanism on the membrane facing capillaries (Fig. 9.2A). Intestinal cells release glucose into blood stream by the carrier mechanism called **Glucose Transporter Type 2 (GluT2)**.

ii. This transporter is not dependent on sodium. It is a uniport, facilitated diffusion system.

iii. Glucose binds to the transporter on one side of the membrane. When fixed, the complex changes configuration. This leads to the closure of the first binding site. At the same time, the binding site is now exposed on the inner side of the membrane, releasing the glucose. The process is called ping-pong mechanism (Fig. 9.2A).

iv. **GluT2 (facilitated transport)** is involved in absorption of glucose from blood stream to cells. GluT2 is present in intestinal epithelial cells, liver cells, beta cells of pancreas and kidney.

v. Since GluT2 has a high Km for glucose, its presence in beta cells is ideally suited for sensing a high glucose level and releasing insulin (See Chapter 24). So this mechanism enables the pancreas to monitor the glucose level and adjust the rate of insulin secretion. Comparison of SGluT and Glu2 is shown in Fig. 9.2B.

3. Glucose Transporter 4

i. **GluT4** is the major glucose transporter in skeletal muscle and adipose tissue (Fig. 9.3).
ii. GluT4 is under the control of insulin. But other glucose transporters are not under the control of insulin.

iii. Clinical application: Insulin induces the movement of intracellular GluT4 molecules to the cell surface and thus increases glucose uptake. In Type 2 diabetes mellitus (Chapter 24), membrane GluT4 is reduced, leading to insulin resistance in muscle and fat cells. In diabetes, entry of glucose into muscle is only half of normal cells.

Absorption of Other Monosaccharides
Glucose and galactose are absorbed by the same transporter, SGluT. It is an energy dependent process, against a concentration gradient, and therefore absorption is almost complete from the intestine. Other monosaccharides are absorbed by carrier mediated facilitated transport. Therefore, absorption is not complete, and the remaining molecules in the intestine will be fermented by bacteria.

GLUCOSE METABOLISM
Abbate Spallanzani (1768) showed that living tissues take up oxygen and give off carbon dioxide. In 1860, Louis Pasteur demonstrated the fermentation process of glucose to alcohol by yeast. Fick (1882) indicated that chemical energy in muscle is converted to contraction of muscle. Gad (1893) found out that lactic acid is formed during muscle contraction. In 1902, Sir Walter Fletcher established that this lactic acid is derived from glycogen. In 1914, Gustav George Embden (1874-1933) studied the lactic acid formation from pyruvate. In 1919, Otto Fritz Meyerhof (1884-1951) enunciated most of the steps of the glycolytic pathway (Nobel prize, 1922). Hexokinase enzyme was first identified by von Euler Chelpin in 1915 (Nobel prize, 1922). Other enzymes in the glycolytic pathway were then identified rapidly; pyruvate decarboxylase by Neuberg in 1911, phospho fructo kinase by sir Arthur Harden in 1920 (Nobel prize, 1929); phospho hexose isomerase by Lohmann in 1933; pyruvate kinase by Parnas in 1934; enolase by Meyerhof in 1935; phospho gluco mutase by Leloir in 1938 (Nobel prize, 1970); glyceraldehyde phosphate dehydrogenase by Warburg in 1939; phosphoglyceromutase by Sutherland in 1942 (Nobel prize, 1971). Between 1935 and 1943, all enzymes of glycolytic pathway were crystallized and characterized by Warburg. He was awarded Nobel prize in 1931 for his earlier work on cellular respiration. He was awarded Nobel prize for second time in 1944 for his contributions in glycolysis; but Hitler did not permit him to receive it!

Clinical Importance of Glucose
1. Glucose is the preferred source of energy for most of the body tissues. Brain cells derive the energy mainly from glucose.
2. When glucose metabolism is deranged, life-threatening conditions may occur. A minimum amount of glucose is always required for normal functioning.
3. Normal fasting plasma glucose level is 70 to 110 mg/dl. After a heavy carbohydrate meal, it rises; but in a normal person, this level is below 150 mg/dl.

GLYCOLYSIS
(EMBDEN-MEYERHOF PATHWAY)
Definition: In the pathway of glycolysis, glucose is split into two 3-carbon pyruvate molecules under aerobic conditions; or lactate under anaerobic conditions, along with production of a small quantity of energy. Glycolysis is derived from the Greek words, glykys = sweet; and lysis = splitting.
Site of reactions: All the reaction steps take place in the cytoplasm.

Significance of the Glycolysis Pathway
1. It is the only pathway that is taking place in all the cells of the body.
2. Glycolysis is the only source of energy in erythrocytes.
3. In strenuous exercise, when muscle tissue lacks enough oxygen, **anaerobic glycolysis forms the major source of energy for muscles.**

4. The glycolytic pathway may be considered as the preliminary step before complete oxidation.
5. The glycolytic pathway provides carbon skeletons for synthesis of non-essential amino acids as well as glycerol part of fat.
6. Most of the reactions of the glycolytic pathway are reversible, which are also used for gluconeogenesis. A summary is shown in Fig. 9.4.

Glucose Entry into Cells
Glucose transporter-4 (GluT4) transports glucose from the extracellular fluid to muscle cells and adipocytes (Table 9.1). This translocase is under the influence of **insulin**. In diabetes mellitus, insulin deficiency hinders the entry of glucose into the peripheral cells. But **GluT2** is the transporter in liver cells; it is not under the control of insulin.

Box. 9.1. Diphosphate and Bisphosphate are Different

When two phosphate groups are linked together and then attached to a parent compound, it is called diphosphate, e.g. adenosine-di-phosphate (Fig. 5.3).
But when phosphoric acid groups are present at two different sites of the compound, it is named as bisphosphate, e.g. fructose-1,6-bisphosphate (Fig. 9.7).
Step 4 of Glycolysis
The 6 carbon fructose-1,6-bisphosphate is cleaved into two 3 carbon units; one glyceraldehyde-3-phosphate and a molecule of dihydroxyacetone phosphate (DHAP) (Fig. 9.8). Since the backward reaction is an aldol condensation, the enzyme is called aldolase. This reaction is reversible.

Step 4-A of Glycolysis
Dihydroxyacetone phosphate is isomerised to glyceraldehyde-3-phosphate by the enzyme phosphotriose isomerase. Thus net result is that glucose is now cleaved into 2 molecules of glyceraldehyde-3-phosphate (Fig. 9.9). The steps 4 and 4-A are together called the splitting phase.

Glycerol portion of the neutral fat can enter into glycolytic or gluconeogenic pathways at this point. Similarly for neutral fat synthesis, glycerol is required which can be derived from glucose through DHAP.

Step 5 of Glycolysis
Glyceraldehyde-3-phosphate is dehydrogenated and simultaneously phosphorylated to 1,3-bisphosphoglycerate (1,3-BPG) with the help of NAD+ (see Fig. 9.10). The enzyme is glyceraldehyde-3-phosphate dehydrogenase. The product contains a high energy bond. This is a reversible reaction.

The oxidation of the aldehyde is an exergonic reaction that drives the synthesis of the high energy compound, 1,3 bisphosphoglycerate with high phosphoryl group transfer potential. The enzyme has a cysteinyl SH group at the active center and is inhibited by iodoacetate. During this reaction, NAD+ is reduced to NADH.

Step 6 of Glycolysis
i. The energy of 1,3-BPG is trapped to synthesize one ATP molecule with the help of bisphosphoglycerate kinase. (Fig. 9.11).

ii. This is an example of substrate level phosphorylation, where energy is trapped directly from the substrate, without the help of the complicated electron transport chain reactions.

iii. When energy is trapped by oxidation of reducing equivalents such as NADH, it is called oxidative phosphorylation. Step 6 is reversible.

Step 7 of Glycolysis
3-phosphoglycerate is isomerized to 2-phospho glycerate by shifting the phosphate group from 3rd to 2nd carbon atom (Fig. 9.12). The enzyme is phosphogluco mutase. This is a readily reversible reaction.

Step 8 of Glycolysis
i. 2-phosphoglycerate is converted to phosphoenol pyruvate by the enzyme enolase. One water molecule is removed (Fig. 9.12).
Fig. 9.14. Step 10; LDH reaction; reversible

ii. A **high energy phosphate bond** is produced. The reaction is reversible.

iii. Enolase requires Mg**, and by removing magnesium ions, **fluoride** will irreversibly inhibit this enzyme. Thus, fluoride will stop the whole glycolysis. So when taking blood for sugar estimation, fluoride is added to blood. If not, glucose is metabolized by the blood cells, so that lower blood glucose values are obtained.

**Step 9 of Glycolysis**

i. Phosphoenol pyruvate (PEP) is dephosphorylated to pyruvate, by **pyruvate kinase**. First PEP is made into a transient intermediary of enol pyruvate; which is spontaneously isomerized into keto pyruvate, the stable form of pyruvate.

ii. One mole of ATP is generated during this reaction. This is again an example of **substrate level phosphorylation** (Fig. 9.13).

iii. The pyruvate kinase is a **key glycolytic enzyme**. This step is **irreversible**.

Fig. 9.16. Summary of regulation of glycolysis

reversal, however, can be brought about in the body with the help of two enzymes (pyruvate kinase and phosphoenol pyruvate carboxy kinase) and hydrolysis of 2 ATP molecules (see gluconeogenesis).

**Step 10 of Glycolysis**

In anaerobic condition, pyruvate is reduced to lactate by lactate dehydrogenase (LDH) (Fig. 9.14). (Greek;...

LDH has 5 iso-enzymes. The cardiac iso-enzyme of LDH will be increased in myocardial infarcts. A summary of glycolysis is shown in Fig. 9.4.

In aerobic conditions, the pyruvate enters the citric acid cycle for complete oxidation. The end product of anaerobic glycolysis is lactate which enters the Cori’s cycle.

**Significance of Lactate Production**

Steps 5 and 10 are Coupled

In the 5th step, for each molecule of glucose entering in the pathway, two molecules of NAD+ are reduced to NADH. The availability of co-enzymes inside a cell is limited. Therefore, this step becomes a bottleneck in the whole reaction sequence.

For smooth operation of the pathway, the NADH is to be reconverted to NAD+. This can be done by oxidative phosphorylation. However, during exercise, there is lack of oxygen. So this reconversion is not possible. Therefore, the cell has to couple some other reaction in which NAD+ is regenerated in the cytoplasm itself. Hence, pyruvate is reduced to lactate; the NAD+ thus generated is reutilised for uninterrupted operation of the pathway (Fig. 9.15).

In RBCs, there are no mitochondria. Hence RBCs derive energy only through glycolysis, where the end product is lactic acid.

**Energy Yield from Glycolysis**

i. During anaerobic (oxygen deficient) condition, when one molecule of glucose is converted to 2 molecules of lactate, there is a net yield of 2 molecules of ATP.

ii. 4 molecules of ATP are synthesized by the 2 substrate level phosphorylations (steps 6 and 9). But 2 molecules of ATP are used in the steps 1 and 3, hence the net yield is only 2 ATP (Table 9.4).

iii. The whole reaction is summarized as

$$\text{Glucose} + 2 \text{ Pi} + 2 \text{ ADP} \rightarrow 2 \text{ Lactate} + 2 \text{ ATP}$$

iv. But when oxygen is in plenty, the two NADH molecules, generated in the glyceraldehyde-3-phosphate dehydrogenase reaction (step 5), can enter the mitochondrial electron transport chain for complete oxidation (Chapter 19). As each NADH provides 2.5 ATPs, this reaction generates $2.5 \times 2 = 5$ ATPs. Thus when oxygen is available, the net gain of energy from the glycolysis pathway is 7 ATPs (Table 9.5).

v. Hence the ATP yield from glycolysis is different in anaerobic and aerobic conditions (compare Tables 9.4 and 9.5).

vi. Pyruvate is later oxidatively decarboxylated to acetyl CoA (see below), which enters into the
citric acid cycle (Chapter 18). Complete oxidation of glucose through glycolysis plus citric acid cycle will yield a net 32 ATPs (Table 9.6).

Note: Previously calculations were made assuming that NADH produces 3 ATPs and FADH generates 2 ATPs. This will amount to a net generation of 38 ATP per glucose molecule. Recent experiments show that these old values are overestimates. Please also see Chapter 19 for details.

### Regulation of Glycolysis

The regulation is summarized in Fig. 9.16. The regulatory enzymes or key enzymes of glycolysis are:

1. Glucokinase/Hexokinase, step 1
2. Phosphofructokinase, step 3 (Table 9.3)
3. Pyruvate kinase, step 9

### Factors Regulating Glycolysis

1. **Glucokinase/Hexokinase**: Phosphorylation of glucose by these enzymes is a reaction which is regulated by feed back inhibition (hexokinase by glucose-6-phosphate) and activated by insulin (glucokinase is induced by insulin). Glucokinase that is active mainly in liver has a high Km for glucose and low affinity. Hence, glucokinase can act only when there is plenty of glucose. Thus, when the supply of glucose is limited, glucose is made available to brain and muscles. (Fig. 9.16).

2. **Phosphofructokinase (PFK)** (step 3) is the most important **rate-limiting** enzyme for glycolysis pathway. ATP and citrate are the most important allosteric inhibitors. AMP acts as an allosteric activator (Fig. 9.16).

3. **Fructose-2,6-bisphosphate (F-2,6-BP)** increases the activity of phospho fructo kinase.

Net generation in glycolytic pathway

Generation in pyruvate dehydrogenase reaction

Generation in citric acid cycle

Net generation of ATP from one glucose mol

Note: Till last edition of the Textbook, calculations were made assuming that in the electron transport chain, NADH produces 3 ATPs and FADH generates 2 ATPs. This will amount to a net generation of 38 ATP per glucose molecule. Recent experiments show that these old values are overestimates, and net generation is only 32 ATPs.
F-2,6-BP is formed from fructose-6-phosphate by the action of an enzyme called PFK-2. (It is different from the PFK1). Fructose-2,6-bisphosphate is hydrolysed to fructose-6-phosphate by fructose-2,6-bisphosphatase. The activities of both the enzymes (PFK2 and fructose-2,6-bisphosphatase) are **reciprocally regulated**. When glucose supply is in plenty, PFK-2 is dephosphorylated and activated; so F-2,6-BP concentration increases; this in turn, activates PFK. Thus glycolysis is favored (Fig. 9.17).

4. **Pyruvate Kinase** catalyses an irreversible step and is a regulatory enzyme of glycolysis. When energy is plenty in the cell, glycolysis is inhibited.

Insulin increases its activity where as glucagon inhibits (Fig. 9.18). Pyruvate kinase is inactive in the phosphorylated state.

5. **Insulin** favors glycolysis by activating the above three key glycolytic enzymes.

6. **Glucagon and glucocorticoids** inhibit glycolysis and favor gluconeogenesis (Tables 9.3 and 9.7).

**CORI'S CYCLE OR LACTIC ACID CYCLE**

i. Definition: It is a process in which glucose is converted to lactate in the muscle; and in the liver this lactate is re-converted into glucose. (Fig. 9.19).

ii. In an actively contracting muscle, pyruvate is reduced to lactic acid which may tend to accumulate in the muscle. The muscle cramps, often associated with strenuous muscular exercise, are thought to be due to lactate accumulation.

iii. To prevent the lactate accumulation, body utilizes Cori's cycle.

iv. This lactic acid from muscle diffuses into the blood. Lactate then reaches liver, where it is oxidized to pyruvate. Thus, it is channelled to gluconeogenesis. Regenerated glucose can enter into blood and then to muscle. This cycle is called Cori's cycle (Fig. 9.19).

v. **Significance of the Cori's cycle**: The lactate produced in the muscle is efficiently reutilized.
by the body. But this is an energy-consuming process. During exercise, lactate production is high, which is utilized by liver to produce glucose. This process needs ATP in significant quantities, which is provided by increased metabolism. This leads to increased oxygen consumption. This is the explanation for the oxygen debt after vigorous exercise.

Pasteur Effect
Under aerobic conditions, glycolysis is inhibited. This inhibitory effect of oxygen on glycolysis is known as Pasteur effect.

Warburg Hypothesis
Otto Warburg has studied glycolysis in various tissues. According to his studies, cancer cells utilize energy from glycolysis and they require less oxygen than their normal counterparts; this is called Warburg hypothesis (1923). Rapidly growing tumor cells produce increased quantities of lactic acid, causing high acidity in the local environment. When this lactate is used for gluconeogenesis by the liver; energy consumption increases. This is one of the reasons for cancer cachexia (rapid loss of weight).

Rapaport Leubering Cycle (BPG Shunt)
In the erythrocytes, step 6 of glycolysis is bypassed. Bis phospho glycerate mutase converts 1,3-bisphospho glycerate (BPG) to 2,3-BPG. Then BPG-phosphatase removes the phosphate group to form 3-phospho glycerate (Fig. 9.20).

Significance of BPG
1. The 2,3-BPG combines with hemoglobin, and reduces the affinity towards oxygen. So, in presence of 2,3-BPG, oxyhemoglobin will unload oxygen more easily in tissues.
2. Under hypoxic conditions the 2,3-BPG concentration in the RBC increases, thus favoring the release of oxygen to the tissues even when PO2 is low.
3. The compensatory increase in 2,3-BPG in high altitudes favors oxygen dissociation. BPG is increased in fetal circulation.
4. In this shunt pathway, no ATP is generated. Please compare figures 9.20 and 9.11.

**METABOLIC FATE OF PYRUVATE**

Under aerobic conditions, pyruvate is converted to acetyl CoA which enters the TCA cycle to be oxidized to CO₂. ATP is generated.

Glycolysis is taking place in cytoplasm. So pyruvate is generated in cytoplasm. This is transported into mitochondria by a pyruvate transporter.

**Fig. 9.23. Pyruvate; metabolic junction point**

**Pyruvate Dehydrogenase Complex**

Inside the mitochondria, pyruvate is oxidatively decarboxylated to acetyl CoA by pyruvate dehydrogenase (PDH). It is a multi-enzyme complex with 5 co-enzymes and 3 apo-enzymes. The co-enzymes needed are:

1. Thiamine pyrophosphate (TPP)
2. Co-enzyme A (CoA)
3. FAD
4. NAD⁺
5. Lipoamide. The lipoic acid, otherwise called thioctic acid has two sulphur atoms and 8 carbon atoms. It can accept or donate hydrogen atoms (Fig. 9.21).

6. The enzyme part of the PDH complex is made up of three component enzymes (Fig. 9.22).

6-A. **Pyruvate Dehydrogenase** (Enzyme 1): It catalyses oxidative decarboxylation. TPP is required in this step. So, Thiamine, a B-complex group vitamin is essential for utilization of pyruvate. The two carbon unit remains attached to the enzyme, as hydroxyethyl thiamine pyrophosphate.

6-B. **Dihydro Lipoyl Trans Acetylase** (Enzyme 2): Then, hydroxymethyl group is oxidized to form an acetyl group and then transferred from TPP to lipoamide to form acetyl lipoamide.

6-C. **Dihydro Lipoyl Dehydrogenase** (Enzyme 3): The last step is the oxidation of lipoamide. At the end of the reaction the cofactors, namely TPP, Lipoamide and FAD are regenerated (Fig. 9.22).

A similar enzyme complex brings about the oxidative decarboxylation of alpha keto glutarate to succinyl CoA in the TCA cycle (Chapter 18).

**Regulation:** PDH is subject to regulation by allosteric mechanisms and covalent modification. Allosteric inhibitors are the products acetyl CoA and NADH. PDH or E1 is covalently modified by phosphorylation by PDH kinase and dephosphorylated by PDH phosphatase. The dephosphorylated form of the enzyme is active. Hence activators of PDH kinase like ATP, NADH and acetyl CoA inhibit PDH reaction. PDH phosphatase is activated by Ca²⁺, Mg²⁺ and AMP; this will increase the rate of PDH reaction where as PDH kinase is inhibited by Ca²⁺. When there is adequate ATP and acetyl CoA, the enzyme is inhibited.

**Importance of Pyruvate Dehydrogenase**

1. **Completely irreversible Process.** There is no pathway available in the body to circumvent this step. Glucose through this step is converted to Box 9.3.

**Clinical Applications of Glycolytic Enzymes**

1. **Lactic acidosis** may be seen in hypoxia, shock, pulmonary failure, alcohol abuse (Chapter 10), and diabetes mellitus (Chapter 24).
2. **Deficiency of glycolytic enzymes.** These conditions are rare, out of which pyruvate kinase deficiency and hexokinase deficiency are comparatively common. Though rare, these deficiency states can lead to hemolytic anemia, because energy depleted RBCs are destroyed. Hexokinase deficient RBCs have a low level of 2,3 BPG and a high affinity for oxygen. On the other hand, a deficiency of pyruvate kinase leads to decreased affinity for oxygen since 2,3 BPG levels are high. Inherited aldolase deficiency also causes hemolysis. In PFK deficiency, muscle weakness is seen.
3. **Pyruvate dehydrogenase (PDH).** PDH requires thiamine pyrophosphate (TPP); this explains the serious afflictions in beriberi due to thiamine deficiency (Chapter 34). TPP deficiency in alcoholism causes pyruvate accumulation in tissues. Inherited PDH deficiency may lead to lactic acidosis.
acetyl CoA from which fatty acids can be synthesized.

2. But the backward reaction is not possible, and so there is no net synthesis of glucose from fat.

3. Pyruvate may be channelled back to glucose through gluconeogenesis. But when pyruvate becomes acetyl CoA, it cannot go back. Thus, pyruvate dehydrogenase step is the committed step towards oxidation of glucose.

4. **Energetics**: The NADH generated in this reaction, enters the electron transport chain to produce 2.5 ATP molecules. (See footnote of Table 9.6).

5. Pyruvate dehydrogenase is regulated by end product inhibition as well as by covalent modification. Phosphorylation of the enzyme by a kinase decreases the activity of the enzyme. Dephosphorylation activates the enzyme. Diseases associated with glycolysis pathway are described in Box 9.3.

---

**Pyruvate as a Junction Point**

Pyruvate occupies an important junction between various metabolic pathways. It may be decarboxylated to acetyl CoA which enters the TCA cycle, or may be utilized for fatty acid synthesis. Pyruvate may be carboxylated to oxaloacetate which is used for gluconeogenesis. These pathways are summarized in Figure 9.23.

**GLUCONEOGENESIS**

1. **Definition**

It is the process by which glucose molecules are produced from non-carbohydrate precursors. These include lactate, glucogenic amino acids, glycerol part of fat and propionyl CoA derived from odd chain fatty acids (Fig. 9.27).

2. **Site**

Gluconeogenesis occurs mainly in the liver, and to a lesser extent in the renal cortex. The pathway is partly mitochondrial and partly cytoplasmic.

3. **Key Gluconeogenic Enzymes**

   1. Pyruvate carboxylase
   2. Phosphoenol pyruvate carboxy kinase
   3. Fructose-1,6-bisphosphatase
   4. Glucose-6-phosphatase

Chapter 9; Major Metabolic Pathways of Glucose

Glucose involves several enzymes of glycolysis, but it is not a reversal of glycolysis. The irreversible steps in glycolysis are circumvented by four enzymes which are designated as the key enzymes of gluconeogenesis (Table 9.7).

1. Pyruvate Carboxylase Reaction
Pyruvate in the cytoplasm enters the mitochondria. Then, carboxylation of pyruvate to oxaloacetate is catalysed by a mitochondrial enzyme, pyruvate carboxylase (Fig. 9.24). It needs the co-enzymes biotin and ATP.

Malate Aspartate Shuttle
The carboxylation of pyruvate (previous reaction) takes place in mitochondria. So, oxaloacetate is generated inside the mitochondria. This oxaloacetate has to be transported from mitochondria to cytosol, because further reactions of gluconeogenesis are taking place in cytosol. This is achieved by the malate aspartate shuttle. Oxaloacetate is first converted to malate, which traverses the membrane and reaches cytoplasm. Malate is then re-converted to oxaloacetate. Malate dehydrogenase is present in both mitochondria and cytoplasm. (Fig. 9.25). Oxaloacetate may also be transported as aspartate formed by transamination of oxaloacetate.

When alanine is the substrate for gluconeogenesis, the malate shuttle predominantly operates, because NADH is also required in the cytoplasm for the gluconeogenesis to continue. When lactate is the substrate for gluconeogenesis, the aspartate shuttle operates, because sufficient NADH is available in the cytoplasm by the LDH reaction.

2. Phosphoenol Pyruvate Carboxy Kinase
In the cytoplasm, PEPCK enzyme then converts oxaloacetate to phosphoenol pyruvate by removing a molecule of CO2. GTP or ITP donates the phosphate (Fig. 9.26).

The net effect of these two reactions is the conversion of pyruvate to phosphoenol pyruvate. This circumvents the irreversible step in glycolysis catalyzed by pyruvate kinase (step 9 of glycolysis).

Partial Reversal of Glycolysis
The phosphoenol pyruvate undergoes further reactions catalyzed by the glycolytic enzymes to form fructose-1,6-bisphosphate (see glycolysis steps 8,7,6,5 and 4). All these reactions are freely reversible.

3. Fructose-1,6-bisphosphatase
Fructose 1,6-bis-phosphate is then acted upon by fructose 1,6-bisphosphatase to form fructose.
-6-phosphate. This will bypass the step of PFK reaction (see step 3 of glycolysis).

Then fructose-6-phosphate is isomerized to glucose-6-phosphate by the freely reversible reaction catalyzed by hexosephosphate isomerase (second step in glycolysis).

4. Glucose-6-phosphatase Reaction
The glucose 6-phosphate is hydrolysed to free glucose by glucose-6-phosphatase.

Glucose-6-phosphate + H₂O -----→ Glucose + Pi

Glucose-6-phosphatase is active in liver. It is present in kidney and intestinal mucosa to a lesser extent, but is absent in muscle.

The detailed steps of gluconeogenesis are shown in Figure 9.27.

Significance of Gluconeogenesis
1. Only liver can replenish blood glucose through gluconeogenesis, because glucose-6-phosphatase is present mainly in liver. So liver plays the major role in maintaining the blood glucose level.

2. During starvation gluconeogenesis maintains the blood glucose level. The stored glycogen is depleted within the first 12-18 hours of fasting. On prolonged starvation, the gluconeogenesis is speeded up and protein catabolism provides the substrates, namely glucogenic amino acids.

3. Energy Requirement: The reactions catalyzed by pyruvate carboxylase, phosphoenol pyruvate carboxy kinase and phospho glycerate kinase require one ATP each; so 3 ATPs are used by 1 pyruvate residue to produce one-half molecule of glucose; or 6 ATPs are required to generate one glucose molecule.

2 pyruvate → 2 oxaloacetate = 2 ATP
2 oxaloacetate → 2 phosphoenol pyruvate (2GTP) = 2 ATP
2 x 3-phosphoglycerate → 2 x 1,3-bisphosphoglycerate = 2 ATP
Total = 6 ATP
Chapter 9; Major Metabolic Pathways of Glucose

Glycolysis (generates 2 ATP)

\[
\text{Glucose} \rightarrow \text{Lactate} \\
\text{Gluconeogenesis (utilises 6 ATP)}
\]

Substrates for Gluconeogenesis

Lactate and glucogenic amino acids are the most important substrates for gluconeogenesis.

1. Lactate

The lactate formed in the muscle is transported to the liver. In the liver cell lactate dehydrogenase converts lactate to pyruvate (Fig. 9.28). The pyruvate enters the gluconeogenic pathway to form glucose. See also Cori’s cycle (Fig. 9.19).

2. Glucogenic amino acids
   i. Glucogenic amino acids are shown in Figure 9.27. (Alanine, glutamic acid, aspartic acid, etc).
   ii. When glucose is not readily available (starvation or diabetes mellitus), the glucogenic amino acids are transaminated to corresponding carbon skeletons. (Fig. 9.27). These then enter the TCA cycle and form oxaloacetate or pyruvate.
   iii. Alanine released from the muscle is the major substrate for gluconeogenesis (Fig. 9.29).

3. Glycerol

The glycerol part of fat is phosphorylated in the liver cytosol by ATP to glycerol-3-phosphate. It is then oxidized to dihydroxy acetone phosphate by an NAD+ dependent dehydrogenase (Fig. 9.31).

4. Propionyl CoA

Propionyl CoA is formed from odd chain fatty acids and carbon skeleton of some amino acids. It is converted to succinyl CoA (see Fig. 11.11). It is a minor source for glucose.

Important: Even chain fatty acids cannot be converted to glucose; they are not substrates for gluconeogenesis.

Regulation of Gluconeogenesis

Gluconeogenesis and glycolysis are reciprocally regulated so that one pathway is relatively inactive when the other is active. The regulatory steps are:

1. Pyruvate Carboxylase

It is an allosteric enzyme. Acetyl CoA is an activator of pyruvate carboxylase so that generation of
oxaloacetate is favored when acetyl CoA level is sufficiently high (Fig. 9.24).

2. Fructose-1,6-bisphosphatase
Citrate is an activator while fructose-2,6-bisphosphate and AMP are inhibitors. All these three effectors have an exactly opposite effect on the phospho fructo kinase (PFK) (Fig. 9.32).

3. ATP
Gluconeogenesis is enhanced by ATP.

4. Hormonal Regulation of Gluconeogenesis
i. The hormones glucagon and gluco corticoids increase gluconeogenesis (Fig. 9.33).
   ii. Glucocorticoids induce the synthesis of hepatic amino transferases thereby providing substrate for gluconeogenesis.
   iii. The high glucagon-insulin ratio also favors induction of synthesis of gluconeogenic enzymes (PEPCK, Fructose-1,6-bisphosphatase and glucose-6-phosphatase).
   iv. At the same time, synthesis of glycolytic enzymes HK, PFK and PK are depressed.
   v. Insulin inhibits the process (Fig. 9.33). A summary of regulatory enzymes of gluconeogenesis is shown in Table 9.8. (Compare with Table 9.3). Clinical significance of pyruvate metabolism is shown in Box 9.4.

GN ratio or DN ratio
During gluconeogenesis proteins are degraded and end-product urea is excreted through urine. The ratio of glucose (dextrose) to urea nitrogen in urine is termed as GN ratio or DN ratio. In such animals, the ratio is 3.65. That means 1 g of nitrogen (from protein) will form 3.65 g of glucose. Since proteins contain 16% nitrogen; 58% of protein is gluconeogenic. GN ratio is enhanced when catabolism is increased, e.g. insulin deficiency, starvation, pyrexia, hyperthyroidism and cancer.

GLYCOGEN METABOLISM
Carl Cori and Gerty Cori were awarded Nobel prize in 1947, for their work on glycogen degradation. Based on his work on

---

**Box 9.4. Clinical Significance of Pyruvate**

1. Pyruvate carboxylase deficiency. It is seen as an inborn error of metabolism, where mental retardation is manifested. Its incidence is 1 in 25,000 births. Lactic acidosis is noticed.

2. Malignant hyperthermia. This may occur when halothane is given as an anesthetic to certain persons. The ryanodine receptor, a calcium-release channel is defective, leading to inappropriate release of calcium from sarcoplasmic reticulum. This results in uncontrolled heat generation, damage of muscle cells, ATP depletion, lactic acidosis and rhabdomyolysis. CPK is markedly elevated. This defect is seen in 1 per 50,000 population.

3. Ethanol (Ethyl alcohol). It inhibits gluconeogenesis. During the metabolism of ethanol the level of cytoplasmic NADH is raised. Thus, the Pyruvate → Malate → Oxaloacetate reactions are reversed. So, excessive ingestion of alcohol results in hypoglycemia. Lactate also accumulates as NADH level is high (Chapter 10).

---

**Fig. 9.34. Reaction of glycogen phosphorylase**

**Fig. 9.35. Glycogenolysis**
glycogen synthesis, Luis Leloir (Argentina) was awarded Nobel prize in 1970. Earl Sutherland (Nobel prize, 1971) studied the role of cyclic AMP as the second messenger in glycogenolysis. Glycogen is a homopolysaccharide with glucose units linked in alpha-1,4 linkages (straight line) and alpha-1,6 linkages (branching point). Branching makes the molecule more globular and less space-consuming. For details of structure, see Figure 6.23.

Functions of Glycogen
1. Glycogen is the storage form of carbohydrates in the human body. The major sites of storage are liver and muscle. The major function of liver glycogen is to provide glucose during fasting. The glycogen content of liver (10 gm/100 gm tissue) is more than in the skeletal muscle (1–2 gm/100 gm). But the total quantity of muscle glycogen is more than liver glycogen because of the larger muscle mass.
2. When blood glucose level falls, liver glycogen is broken down and helps to maintain blood glucose level. After taking food, blood glucose tends to rise, which causes glycogen deposition in liver. About 5 hours after taking food, the blood glucose tends to fall. But, glycogen is lysed to glucose so that the energy needs are met. After about 18 hours fasting, most of the liver glycogen is depleted, when depot fats are hydrolysed and energy requirement is met by fatty acid oxidation.
3. The function of muscle glycogen is to act as reserve fuel for muscle contraction.
4. All the enzymes related to glycogen metabolism are cytoplasmic.

Degradation of Glycogen (Glycogenolysis)
1. Glycogen Phosphorylase
   i. Glycogen phosphorylase removes glucose as glucose-1-phosphate from glycogen (phosphorylasis) (Fig. 9.34). It contains pyridoxal phosphate (PLP) as a prosthetic group. The alpha-1,4 linkages in the glycogen are cleaved.
   ii. It removes glucose units one at a time. Enzyme sequentially hydrolyses alpha-1,4 glycosidic linkages, till it reaches a glucose residue, 3-4 glucose units away from a branch point (Fig. 9.35). It cannot attack the 1,6 linkage at branch point.
   iii. If glycogen phosphorylase alone acts on a glycogen molecule, the final product is a highly branched molecule; it is called limit dextrin.
2. Debranching by bifunctional (two) Enzymes
   i. Then a block of 3 glucose residues (trisaccharide unit) are transferred from the
branching point to another branch. This enzyme is alpha-1,4 → alpha-1,4 glucan transferase.

ii. Now the branch point is free. Then alpha-1,6-glucosidase (debranching enzyme) can hydrolyse the remaining glucosyl unit held in alpha-1,6 linkage at the branch point (Fig. 9.35).

iii. This glucose residue is released as free glucose. At this stage, the ratio of glucose-1-phosphate to free glucose is about 8:1.

iv. The transferase and alpha-1,6-glucosidase will together convert the branch point to a linear one. With the removal of the branch point, phosphorylase enzyme can proceed with its action.

3. Phosphoglucu mutase
Phosphorylase reaction produces glucose-1-phosphate while debranching enzyme releases glucose. The glucose-1-phosphate is converted to glucose-6-phosphate by phosphoglucomutase (Fig. 9.36).

4. Glucose-6-phosphatase in Liver
Next, hepatic glucose-6-phosphatase hydrolyses glucose-6-phosphate to glucose. The free glucose is released to the blood stream.

5. Muscle Lacks Glucose-6-phosphatase
Important: Muscle will not release glucose to the blood stream, because muscle tissue does not contain glucose-6-phosphatase. Instead, in muscle, glucose-6-phosphate undergoes glycolysis to produce ATP for muscle contraction.

Energetics
i. In muscle, the energy yield from one glucose residue derived from glycogen is 3 ATP molecules, because no ATP is required for initial phosphorylation of glucose (step 1 of glycolysis).

ii. If glycolysis starts from free glucose only 2 TPs are produced.

GLYCOGEN SYNTHESIS (GLYCOGENESIS)
The glycogen synthesis occurs by a pathway distinctly different from the reversal of glycogen
breakdown, which would prevent the operation of futile cycles. The steps are:

1. Activation of Glucose
   UDP glucose is formed from glucose-1-phosphate and UTP (uridine triphosphate) by the enzyme UDP-glucose pyrophosphorylase.

\[
\text{UDP-glucose-pyrophosphorylase} \quad \text{Glucose-1-phosphate} + \text{UTP} \rightarrow \text{UDP-glucose phosphate} + \text{PPi}
\]

2. Glycogen Synthase
   The glucose moiety from UDP-glucose is transferred to a glycogen primer (glycogenin) molecule. The primer is essential to accept the glycosyl unit. The primer is made up of a protein-carbohydrate complex. It is a dimeric protein, having two identical monomers. An oligosaccharide chain of 7 glucose units is added to each monomer.

   \[
   \text{Glycogen synthase} \\
   \text{Glycogen primer (n)} \rightarrow \text{Glycogen (n+1)} + \text{UDP-glucose} + \text{UDP}
   \]

   In the next step, activated glucose units are sequentially added by the enzyme glycogen synthase (Fig. 9.37). The glucose unit is added to the nonreducing (outer) end of the glycogen primer to form an alpha-1,4 glycosidic linkage and UDP is liberated.

3. Branching Enzyme
   i. The glycogen synthase can add glucose units only in alpha-1,4 linkage. A branching enzyme is needed to create the alpha-1,6 linkages.
   ii. When the chain is lengthened to 11 - 12 glucose residues, the branching enzyme will transfer a block of 6 to 8 glucose residues from this chain to another site on the growing molecule. The enzyme amylo-1,4\rightarrow 1,6-transglucosidase (branching enzyme) forms this alpha-1,6 linkage (Fig. 9.37).
   iii. To this newly created branch, further glucose units can be added in alpha-1,4 linkage by glycogen synthase.

Regulation of Glycogen Metabolism
   i. The synthetic and degradative pathways are reciprocally regulated to prevent futile cycles.
   ii. The phosphorylated form of glycogen phosphorylase is active; but glycogen synthase becomes inactive on phosphorylation. The covalently modified phosphorylase is active even without AMP. Active (dephosphorylated) glycogen synthase is responsive to the action of glucose-6-phosphate. Covalent modification modulates the effect of allosteric regulators. The hormonal control by covalent modification and allosteric regulation are interrelated.
   iii. These hormones act through a second messenger, cyclic AMP (cAMP) (for structure see Fig. 39.8). The mechanism is shown in Figures 9.38 and 9.39.
   iv. The covalent modification of glycogen phosphorylase and synthase is by a cyclic AMP mediated cascade. Specific protein kinases bring about phosphorylation and protein phosphatases cause dephosphorylation.
2. Generation of Cyclic AMP (cAMP)
   i. Both liver and muscle phosphorylases are activated by a cyclic AMP mediated activation cascade triggered by the hormonal signal.
   ii. The hormones epinephrine and glucagon can activate liver glycogen phosphorylase but glucagon has no effect on the muscle.
   iii. When the hormone binds to a specific receptor on the plasma membrane, the enzyme adenyl cyclase is activated which converts ATP to cyclic AMP (cAMP).
   iv. When level of cyclic AMP rises, it will activate a protein kinase (Fig. 9.38).

2-A. Protein Kinase Activation
The protein kinase is inactive when the catalytic (C) and regulatory (R) subunits are associated with each other.

Earl Sutherland (Nobel Prize, 1971) studied the role of cyclic AMP as the second messenger in glycogenolysis. In 1992, Nobel prizes were awarded to Edwin Krebs and Edmond Fisher for their work on protein kinase, phosphorylase kinase and phosphorylase phosphatase.

The cAMP combines with the R subunit so that the C subunit is free to have its catalytic activity. PKA is an enzyme that can phosphorylate serine and threonine residues of several enzyme proteins and is activated by cAMP which combines with the regulatory subunit of PKA. In the absence of cAMP, PKA is an inactive tetramer.

\[ R2C2 + 4 \text{ cAMP} \rightarrow 2C + R2 \text{(cAMP)}4 \]

The intracellular concentration of cAMP therefore decides the level of active PKA and cAMP level depends on the activity of adenylate cyclase and phospho diesterase. Cyclic AMP level is increased by glucagon and decreased by insulin.

\[
\text{ATP} \xrightarrow{\text{Adenylate cyclase}} \text{cAMP} \xrightarrow{\text{PDE}} 5'\text{AMP} + \text{Glucagon} + \text{Insulin}
\]

2-B. Phosphorylase Kinase Activation
The active protein kinase can now convert the phosphorylase kinase to an active phosphorylated form, which converts phosphorylase-b to phosphorylase-a (Fig. 9.39).

Phosphorylase kinase itself is a tetrameric enzyme (alpha, beta, gamma, delta). Of these the gamma subunit has the catalytic site and the other 3 subunits have regulatory effects. Phosphorylase kinase is activated by Ca++ and phosphorylation of alpha and beta subunits by PKA. Phosphorylation of alpha and beta subunits relieves autoinhibition of catalytic activity of gamma subunit. Binding of Ca++ to the delta subunit which is identical to calmodulin (CaM) is also necessary for full activity of delta subunit since it also has a role in dysregulating the gamma subunit. Calcium triggers muscle contraction as well as glycogen breakdown through the action of phosphorylase kinase. The rate of glycogenolysis is linked to rate of muscle contraction.

The dephosphorylation of the active form by PP1 involves removal of phosphate group from phosphorylase a and alpha and beta subunits of phosphorylase kinase. The activity of protein phosphatase 1 (PP1) is controlled differently in liver

Table 9.9. Regulators of glycogen metabolism (L=Liver, M= muscle)
and muscle. The catalytic subunit of PP1 in muscle is active only when it is bound to glycogen through the glycogen binding GM subunit. The phosphorylation of PP1 by an insulin stimulated protein kinase (site1) activates the enzyme whereas phosphorylation at site2 by PKA makes its action ineffective. When cAMP level is high, PP1 is inhibited by inhibitor1 which is activated by phosphorylation by PKA. The effect of cyclic AMP is not only by increasing the phosphorylation of enzymes, but also by decreasing dephosphorylation.

3. Glycogen Phosphorylase in Liver and Muscle
   a. Liver: The liver phosphorylase-b is the inactive form. It becomes active on phosphorylation. The active enzyme is denoted as phosphorylase-a. The enzyme is inhibited by ATP and glucose-6-phosphate (Fig. 9.38).

   In the liver the PP1 is regulated differently through the intermediary of glycogen binding subunit (GL). GL complex can bind to R and T forms of phosphorylase a, but the phosphate group attached to ser14 is exposed only in the T state, so that PP1 can convert phosphorylase a to phosphorylase b. Glucose is an allosteric inhibitor of phosphorylase a. Insulin favors this effect by promoting the uptake and phosphorylation of glucose.

   b. Muscle: Skeletal muscle glycogen is degraded only when the demand for ATP is high. The regulation of glycogenolysis in skeletal muscle is by epinephrine. Glucagon has no effect on muscle glycogenolysis. AMP formed by degradation of ATP during muscle contraction is an allosteric activator of phosphorylase b.

   The active form of phosphorylase is referred to as ‘a’ (active, phosphorylated) and the relatively inactive dephosphorylated form as ‘b’. On the other hand, the active glycogen synthase (a) is dephosphorylated and phosphorylated (b) is relatively inactive.

   Glycogen phosphorylase is activated by phosphorylation by phosphorylase kinase that adds phosphate group to a specific serine residue of phosphorylase b (ser14). This phosphorylase kinase, in turn, is activated by protein kinase A or cyclic AMP dependent protein kinase. Phosphoprotein phosphatase I dephosphorylates both phosphorylase kinase and phosphorylase b. Phosphorylase b is sensitive to allosteric effectors but phosphorylase a is not sensitive. High concentration of ATP and Glucose-6-phosphate in the cell will inhibit phosphorylase b.

4. Glycogen Synthase
   i. Glycogen synthase and phosphorylase activities are reciprocally regulated (Fig. 9.39).
ii. The same protein kinase, which phosphorylates the phosphorylase kinase would also phosphorylate glycogen synthase.

iii. The activity of the glycogen synthase is markedly decreased on phosphorylation. Insulin promotes glycogen synthesis by favoring dephosphorylation.

Glycogen synthase is active in the dephosphorylated state. Phosphorylase kinase can phosphorylate glycogen synthase and inactivate the enzyme. PKA can also inactivate the enzyme by phosphorylation. Ca++ and calcium dependent cam kinase also phosphorylate the enzyme.

Relative rates of glycogen synthesis and breakdown are therefore controlled by the action of PKA, phosphorylase kinase and PP1. PP1 can activate glycogen synthase only after dephosphorylating and inactivating phosphorylase a. The regulation of glycogen phosphorylase and synthase is a typical example of multisite phosphorylation (primary and secondary sites) for metabolic regulation.

Control by allosteric effectors is superimposed on covalent modification. Glucose-6-phosphate can activate glycogen synthesis. Insulin activates PP1 and PDE which decreases cAMP level and increases G6P level to promote glycogen synthesis.

The reciprocal regulation of glycogenolysis and glycogenesis is by covalent modification (phosphorylation and dephosphorylation). Insulin and glucagon are the major regulatory hormones, although epinephrine has stimulatory effect on glycogenolysis in both liver and muscle. They bring about alterations in the activity of protein kinases and phosphatases by varying the level of cAMP.

5. Summary of Regulation
i. The key enzyme for glycogenolysis is phosphorylase, which is activated by glucagon and adrenaline, under the stimulus of hypoglycemia.

Glycogen metabolism is regulated by coordinated regulation of glycogen synthase and glycogen phosphorylase. The regulatory mechanisms include allosteric control as well as hormonal control by covalent modification of enzymes. The allosteric effectors are ATP, Glucose-6-phosphate and AMP. The regulation in muscle and liver is given in Table 9.9.

GLYCOGEN STORAGE DISEASES
These are inborn-errors of metabolism. That phrase was coined by Sir Archibald Garrod.

Glycogen Storage Disease Type-I
1. It is also called Von Gierke's Disease. Most common type of glycogen storage disease is type I.
2. Incidence is 1 in 100,000 live births. Salient features of the disease are:
3. Glucose-6-phosphatase is deficient.
4. Fasting hypoglycemia that does not respond to stimulation by adrenaline. The glucose cannot be released from liver during over night fasting (see Box 10.4 for neonatal hypoglycemia).
5. Hyperlipidemia, lactic acidosis and ketosis.
6. Glucose-6-phosphate is accumulated, so it is channeled to HMP shunt pathway (Chapter 10) producing more ribose and more nucleotides.
7. Purines are then catabolized to uric acid, leading to hyperuricemia (see Chapter 39).
8. Glycogen gets deposited in liver. Massive liver enlargement may lead to cirrhosis.
9. Children usually die in early childhood.
10. Treatment is to give small quantity of food at frequent intervals.

Other glycogen storage diseases (type II to X) are shown in Table 9.10. They are very rare, incidence being 1 in 1 million births.

Blood glucose level is maintained in a very narrow limit in normal persons. The homeostasis of blood sugar and abnormal conditions are explained in Chapter 24.
CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:
1. Hexose monophosphate shunt pathway
2. Significance of the pathway
3. Polyol pathway
4. Fructose metabolism
5. Galactose metabolism
6. Metabolism of alcohol
7. Glycoproteins
8. Blood group antigens
9. Mucopolysaccharidoses

HEXOSE MONOPHOSPHATE (HMP) SHUNT PATHWAY

It is also known as "pentose phosphate pathway"; "Dickens-Horecker pathway"; "Shunt pathway" or "Phosphogluconate oxidative pathway". Instead of glucose going through the glycolytic pathway, it is shunted through this pathway; so it is known as the shunt pathway. In the glycolysis there are a few bisphosphate intermediates; but in this pathway, there are monophosphates only; hence this is called hexose monophosphate (HMP) pathway. The reactions involve the intermediate formation of pentose phosphates; hence this is also called pentose phosphate pathway. Since the first carbon atom of glucose is liberated as CO₂, it is called the direct oxidative pathway of glucose metabolism.

About 10% of glucose molecules per day are entering in this pathway. The liver and RBC metabolise about 30% of glucose by this pathway. The major purpose of this pathway is generation of reduced NADPH and pentose phosphates for nucleotide synthesis (See Box 10.1).

Overview of the Shunt Pathway

The HMP shunt pathway has oxidative and non-oxidative phases. During the oxidative phase, glucose-6-phosphate is oxidized with the generation of 2 molecules of NADPH, and one molecule of pentose phosphate, with the liberation of one molecule of CO₂. During the non-oxidative phase, the pentose phosphate is converted to intermediates of glycolysis.

A. Oxidative Phase

Step 1 of HMP Pathway

Glucose-6-phosphate is oxidized by NADP⁺ dependent Glucose-6-phosphate dehydrogenase (GPD). 6-phosphogluconate is formed. Instead of glucose going through the glycolytic pathway, it is shunted through this pathway; so it is known as the shunt pathway. In the glycolysis there are a few bisphosphate intermediates; but in this pathway, there are monophosphates only; hence this is called hexose monophosphate (HMP) pathway. The reactions involve the intermediate formation of pentose phosphates; hence this is also called pentose phosphate pathway. Since the first carbon atom of glucose is liberated as CO₂, it is called the direct oxidative pathway of glucose metabolism.

Box 10.1. NAD and NADP are Different

NADH is used for reducing reactions in catabolic pathways, e.g. pyruvate to lactate. NADH enters the electron transport chain, and ATP is generated. NADPH is used for reductive biosynthetic reactions, e.g. de novo synthesis of fatty acid, synthesis of cholesterol, etc. NADPH is generated mainly by the HMP shunt pathway. NADPH is not entering the electron transport chain; and NADPH will not generate ATP.

NADP differs from NAD in having an additional phosphate group (Chapter 34). These two coenzymes are specific for enzymes; they are not interchangeable.
Step 6: Transaldolase Reaction
The next group transfer reaction involves the transfer of a 3 carbon unit, from sedoheptulose-7-phosphate to glyceraldehyde-3-phosphate to form fructose-6-phosphate. Here also the donor is a ketose and acceptor is an aldose (Step 6, Fig. 10.4). Summary: $7C + 3C = 6C + 4C$.

Step 7: Second Transketolase Reaction
In another transketolase reaction a 2C unit is transferred from xylulose-5-phosphate to erythrose-4-phosphate to form fructose-6-phosphate and glyceraldehyde-3-phosphate (Step 7, Fig. 10.4). Summary: $5C + 4C = 6C + 3C$.

Step 8: Regeneration of Glucose-6-Phosphate
Two molecules of glyceraldehyde-3-phosphate formed in step 7 are condensed to form one
fructose-6-phosphate (reversal of step 4 of glycolysis). Fructose-6-phosphate is then converted to glucose-6-phosphate (reversal of step 2 of glycolysis). A summary of the whole pathway is depicted in Figure 10.4.

**Regulation of HMP Shunt Pathway**

The pathway is mainly regulated by the level of NADP⁺. The first reaction catalyzed by GPD is the **rate-limiting** step and it is inhibited by NADPH. The oxidative phase is therefore controlled by the level of NADP⁺ and non-oxidative phase by the requirement of pentoses. **Insulin** will induce GPD and therefore will increase the overall pathway.

When more NADPH is needed, the pathway proceeds to completion with the equivalent of one molecule of glucose being completely oxidized to CO₂. The reaction may be summarized as:

\[
\text{G-6-P} + 12 \text{NADP}^+ + 7\text{H}_2\text{O} \rightarrow 6 \text{CO}_2 + 12 \text{NADPH} + 12 \text{H}^+ + \text{Pi}
\]
Summary of Shunt Pathway

Suppose, 6 molecules of glucose (6 x 6 = 36 carbons) are entering in this pathway. The first carbon atoms of all 6 glucose molecules are removed as 6 molecules of CO₂. (This is equivalent to complete oxidation of 1 molecule of glucose). In this process, 12 NADPH are generated. The remaining 6 molecules of 5-carbon pentoses (6 x 5 = 30C) are interchanged in such a way that 5 molecules of glucose (5 x 6 = 30C) are regenerated. This is summarized in Figure 10.4.

Physiological Significance of the Pathway

Please see summary in Box 10.2.

Box 10.2. Metabolic Role of NADPH formed by HMP Shunt Pathway

1. Required for reductive biosynthesis, such as fatty acid, cholesterol and steroids
2. Free radical scavenging
3. RBC membrane integrity
4. Prevention of formation of met-hemoglobin
5. Detoxification
6. Preserving transparency of lens of eye
7. Bactericidal activity of macrophages
8. Production of ribose and deoxyribose for DNA and RNA synthesis

Box 10.3. Clinical Aspects of HMP Shunt Pathway

1. Glucose-6-phosphate dehydrogenase deficiency
2. Drug induced hemolytic anemia
3. Met-hemoglobinemia
4. Thiamine deficiency leads to reduced transketolase activity

1. Pathway is Operating in Following Organs:
   i. Liver
   ii. Adipose tissue
   iii. Adrenal cortex
   iv. Mammary glands
   v. Testes and ovaries
   vi. RBCs
   vii. Lens of eye

A. The oxidative phase of the pathway is seen in the above organs, where NADPH generation is required for lipid synthesis or steroid synthesis.

B. The non-oxidative phase is present in all tissues, and so synthesis of ribose is possible in all tissues of the body.

2. Generation of Reducing Equivalents

The major metabolic role of the pathway is to provide cytoplasmic NADPH for reductive biosynthesis of fatty acids, cholesterol and steroids (Chapters 11 and 12).

3. Free Radical Scavenging

Free radicals (super oxide, hydrogen peroxide) are continuously produced in all cells. These will destroy...
**5. Prevention of Met-hemoglobinemia**

NADPH is also required to keep the iron of hemoglobin in the reduced (ferrous) state and to prevent the accumulation of met-hemoglobin (See Chapter 22). Met-hemoglobin cannot carry oxygen.

**6. Detoxification of Drugs**

Most of the drugs and other foreign substances are detoxified by the liver microsomal P450 enzymes, with the help of NADPH.

**7. Lens of Eye**

Maximum concentration of NADPH is seen in lens of eye. NADPH is required for preserving the transparency of lens.

**8. Macrophage Bactericidal Activity**

NADPH is required for production of reactive oxygen species (ROS) (superoxide anion radical) by macrophages to kill bacteria (Fig. 10.6).

**9. Availability of Ribose**

Ribose and deoxyribose are required for DNA and RNA synthesis. Ribose is also necessary for nucleotide coenzymes. Reversal of nonoxidative phase is present in all tissues, by which ribose could be made available.

**10. What about ATP?**

*ATP is neither utilized nor produced by the HMP shunt pathway.* Cells do not use the shunt pathway for energy production.

**Clinical Significance of Shunt Pathway**

Please see summary in Box 10.3.

**1. GPD Deficiency**

i. The enzyme glucose-6-phosphate dehydrogenase (GPD) may be deficient in some persons (see Chapter 23). It is the most common enzyme deficiency seen in clinical practice. The defect is transmitted as an *X-linked recessive* trait.

ii. It will lead to *drug-induced hemolytic anemia*. The deficiency is manifested only when exposed to certain drugs or toxins, e.g. intake of *antimalarial drugs* like primaquine. Primaquin stimulates peroxide formation inside RBC. In GPD deficient cells, the level of NADPH is low; hence further production of peroxides will lead to cell lysis.

---

**Fig. 10.7. Glucuronic acid pathway**

DNA, proteins, fatty acids and all biomolecules, and in turn cells are destroyed. The free radicals are inactivated by enzyme systems containing superoxide dismutase (SOD), peroxidase (POD) and glutathione reductase (GR). Reduced GR is regenerated with the help of NADPH (Fig. 10.5).

4. **Erythrocyte Membrane Integrity**

NADPH is required by the RBC to keep the glutathione in the reduced state (Fig. 10.5). In turn, reduced glutathione will detoxify the peroxides and free radicals formed within the RBC (See Chapter 20). So, **NADPH, glutathione and glutathione reductase** together will preserve the integrity of RBC membrane.
iii. Similarly, ingestion of toxic glycosides present in fava beans may have similar effect (Favism).

iv. Sulpha drugs and furadantin may also precipitate the hemolysis. This will lead to jaundice and severe anemia.

v. The geographical distribution of GPD deficiency correlates well with the malarial endemicity. The enzyme deficiency offers resistance to plasmodium infection (See Chapter 22). The parasite requires reduced glutathione for its survival, which will not be available in adequate amounts in deficiency of GPD. GPD deficiency is reported from almost all States of India.

2. Met-hemoglobinemia
GPD deficient persons will show increased methemoglobin in circulation, even though cyanosis may not be manifested.

3. Thiamine Deficiency
The transketolase reaction is measured in RBCs as an index of the thiamine status of an individual.

The occurrence and manifestation of Wernicke's Korsakoff's syndrome (encephalopathy) which is seen in alcoholics and those with thiamine deficiency is due to a genetic defect in the enzyme transketolase.

Glucuronic Acid Pathway of Glucose Metabolism
The pathway is shown in Figure 10.7.

Importance of the glucuronic acid pathway
It provides UDP-glucuronic acid, which is the active form of glucuronic acid. It is used for the following purposes:
1. Conjugation of bilirubin
2. Conjugation of steroids
3. Conjugation of various drugs which will make them more water soluble and more easily excretable.

Effect of Drugs
Barbiturates, antipyrine and aminopyrine will increase the uronic acid pathway, leading to availability of more glucuronate for conjugation purpose.

Vitamin C in Lower Animals
The enzyme L-gulonolactone oxidase is absent in human beings, primates, guinea pigs and bats. Hence ascorbic acid cannot be synthesized by these organisms. Hence ascorbic acid is an essential nutrient in the diet of human beings.

Essential Pentosuria
i. It is one of the members of the Garrod’s tetrad.
   The incidence is 1 in 2,500 births.
ii. It is an inborn error of metabolism. In the pathway (Fig. 10.7), L-xylulose is converted...
Box 10.4. Neonatal Hypoglycemia

Neonatal hypoglycemia is seen in:
1. Glycogen Storage Disease Type I (Chapter 9)
2. Fructose Intolerance (Chapter 10)
3. Galactosemia (Chapter 10)
4. Medium Chain Fatty Acyl CoA Dehydrogenase deficiency (See Chapter 13)
5. Long Chain Fatty Acyl CoA Dehydrogenase deficiency (See Chapter 11)

Premature infants are more prone to hypoglycemia because
a. Decreased levels of PEPCK and
b. Decreased gluconeogenesis
c. Low hepatic glycogen stores
d. Inability to produce and utilize ketone bodies
e. Larger brain:body ratio

to D-xylulose by two enzymes, xylitol dehydrogenase and xylulose reductase. Absence of any of these enzymes leads to the pentosuria.

iii. L-xylulose is excreted in urine and gives a positive Benedict’s test.

iv. Barbiturates, aminopyrine, etc. will induce uronic acid pathway and will increase xylulosuria in such patients.

v. This condition does not produce any harm; but it should be differentiated from diabetes mellitus.

POLYOL PATHWAY OF GLUCOSE
Sorbitol is very poorly absorbed from intestine. It involves the reduction of glucose by aldose reductase to sorbitol, which can then be oxidized to fructose. This would amount to the interconversion of glucose to fructose (Fig. 10.8).

Glucose when converted to sorbitol, cannot diffuse out of the cell easily and gets trapped there. Sorbitol is normally present in lens of eyes. But in diabetes mellitus, when glucose level is high, the sorbitol concentration also increases in the lens. This leads to osmotic damage of the tissue and development of cataract. Galactitol also causes cataract (see under galactose metabolism).

Fructose is present in semen in large quantities. It is produced by the polyol pathway. The polyol pathway is active in brain and fructose is seen in CSF. This pathway is inactive in liver.

FRUCTOSE METABOLISM
1. Fructose is a ketohexose present in fruits, honey and sucrose. Soft drinks have the sweetener, corn sugar, which has a high fructose content and is sweeter than sucrose. Fructose is promptly metabolized by the liver.
2. Fructose is phosphorylated by fructokinase, an enzyme present in liver with a high affinity for fructose (Fig. 10.9). Fructokinase phosphorylates the substrate at 1st position, whereas hexokinase action is on the 6th position. Fructokinase is not dependent on insulin. So fructose is more rapidly utilized in normal persons, because GK and PFK metabolic bottlenecks are not encountered in fructose metabolism.

Therefore, in theory, fructose will be better utilized in patients with diabetes mellitus, because the first few enzymes of fructose utilization do not require insulin. But in experiments, fructose was found to be deleterious in diabetes patients. Fructose rapidly enters the tissues, leading to enhanced fatty acid synthesis, raised serum triglycerides and increased LDL cholesterol level in blood; all these are atherogenic and harmful.

Fructose metabolism in liver bypasses the PFK control point; hence fructose increases the flux of glycolytic pathway, leading to lipogenesis. Moreover, glycerol phosphate required for TAG synthesis is provided by the metabolism of fructose, leading to the increase in TAG pool in the body. Phosphorylation of fructose by fructokinase depletes the cell of ATP. Low ATP levels enhance oxidative phosphorylation leading to lowering of Pi levels in cell. This will remove the inhibitory effect on adenosine deaminase. There is increased rate of conversion of AMP to IMP and then to uric acid.

Accumulation of fructose-1-phosphate also inhibits gluconeogenesis
3. In muscle, fructose is phosphorylated by hexokinase to fructose-6-phosphate.
4. The fructose-1-phosphate is then cleaved by the enzyme, fructose-1-phosphate-aldolase or aldolase-B. The products are glyceraldehyde and dihydroxyacetone phosphate ( Fig. 10.9).
5. Fructose is mainly metabolized by liver, but free fructose is seen in large quantities in seminal plasma. The energy for mobility of spermatozoa is mainly derived from fructose. Fructose is secreted by seminal vesicles.
6. In some persons azoospermia is seen due to a block in the duct. In such persons fructose is estimated in semen. If fructose is present, the block is above the seminal vesicular duct; if absent, block is after the seminal vesicles.
7. High fructose levels are known to be related to aging and myocardial infarction. Fructose participates in glycation
10 times faster than glucose and the decreased antioxidant contribute effects to ischemic heart disease.

**Hereditary Fructose Intolerance (HFI)**

i. It is an autosomal recessive inborn error of metabolism. Incidence of the disease is 1 in 20,000 births, while 1 in 70 persons are carriers of the abnormal gene.

ii. The defect is in aldolase-B; hence fructose-1-phosphate cannot be metabolized (Fig. 10.9).

iii. This is seen when sucrose (containing fructose) is introduced in the diet of infants, usually around 6 months of age.

iv. Accumulation of fructose-1-phosphate will inhibit glycogen phosphorylase. This leads to accumulation of glycogen in liver and associated hypoglycemia (Box 10.4).

v. Vomiting and loss of appetite are seen. The infants often fail to thrive. Hepatomegaly and jaundice may occur. If liver damage progresses, death will occur.

vi. Fructose is also excreted in urine, which gives positive Benedict's test.

vii. Withdrawal of fructose from the diet will immediately relieve the symptoms.

**Fructosuria**

This is a benign metabolic defect due to deficiency of fructokinase (Fig. 10.9). There is no abnormality other than excretion of fructose in urine. Fructose is not a dietary essential. Urine gives positive Benedict's and Seliwanoff's tests. Incidence is 1 in 130,000 births.

**GALACTOSE METABOLISM**

1. The term galactose is derived from Greek word, "gala" = milk. Galactose is an aldohexose and is the 4th epimer of glucose.

2. Galactose is a constituent of lactose of milk sugar, and is taken in the diet. Galactose is not an essential nutrient, because UDP glucose can form UDP galactose (Fig. 10.10).

3. Galactose is metabolized almost exclusively by the liver and therefore galactose tolerance test is done to assess the functional capacity of the liver. UDP galactose is the active donor of galactose during synthetic reactions.

4. Galactose is necessary for synthesis of the following.

   i. **Lactose Synthesis**

      \[
      \text{UDP glucose} \xrightarrow{\text{Epimerase}} \text{UDP galactose} \\
      \text{Lactose synthase} \hspace{2cm} \text{Lactose} \\
      \text{UDP galactose + glucose} \xrightarrow{\text{Lactase}} \text{Lactose}
      \]

      Lactose synthesis is seen in lactating mammary glands. See also Chapter 31.

   ii. Synthesis of glycosaminoglycans

   iii. Synthesis of cerebrosides

   iv. Synthesis of glycolipids

   v. Synthesis of glycoproteins.
Galactose Metabolism

1. **Galactokinase reaction**: Galactose is first phosphorylated by galactokinase to galactose-1-phosphate (step 1, Fig. 10.10).

2. **Galactose-1-phosphate uridyl transferase**: This is the rate-limiting enzyme in the galactose metabolism (Step 2, Fig. 10.10). UDP-galactose may be used as such for synthesis of compounds containing galactose (e.g., lactose).

3. **Epimerase reaction**: By this reaction, galactose is channeled to the metabolism of glucose (Step 3, Fig. 10.10). Since the reaction is freely reversible, even if the dietary supply of galactose is deficient, UDP-glucose can be epimerized to UDP-galactose.

4. **Alternate pathway**: The galactose-1-phosphate pyrophosphorylase in liver becomes active only after 4 or 5 years of life. The enzyme will produce UDP-galactose directly which can be epimerized to UDP-glucose (Step 4, Fig. 10.10).

Galactosemia

1. There is deficiency of enzyme **galactose-1-phosphate uridyl transferase**. It is an inborn error of metabolism. The incidence is 1 in 35,000 births. Hermann Kalckar described it in 1958.

2. Due to the block in this enzyme, galactose-1-phosphate will accumulate in liver. This will inhibit galactokinase as well as glycogen phosphorylase. **Hypoglycemia** is the result (Box 10.4).

3. Bilirubin uptake is less and bilirubin conjugation is reduced; so **unconjugated bilirubin** level is increased in blood (for bilirubin, see Chapter 21).

4. There is enlargement of liver, jaundice and severe **mental retardation**.

5. Free galactose accumulates, leading to **galactosemia**. It is partly excreted in urine (galactosuria).

6. Galactose is reduced to dulcitol (See Chapter 6). The accumulation of dulcitol in the lens results in cataract due to its osmotic effect. This is called **congenital cataract** and is a very characteristic feature of galactosemia.

7. Galactose-1-phosphate may get deposited in renal tubules, producing tubular damage leading to generalized **amino aciduria**. These salient clinical findings are summarized in Fig. 10.11.

8. **Diagnosis**: Clinical manifestation including **congenital cataract** and **presence of galactose** in urine as well as elevated blood galactose levels will help in the diagnosis. Collection of fetal cells by **amniocentesis** may be useful in prenatal diagnosis. Heterozygous parents could be detected by elevated galactose level in blood after a galactose load.

9. **Treatment**: If lactose is withdrawn from the diet, most of the symptoms recede. But mental retardation, when established, will not improve. Hence early detection is most important. For affected infant **lactose-free diet** is given. Such special diets may be withdrawn after 4 years, when galactose-1-phosphate pyrophosphorylase (step 4, Fig. 10.10) becomes active.

Galactokinase Deficiency

A variant of the disease occurs due to the deficiency of galactokinase. But here the symptoms are milder. This is because galactose-1-phosphate is not formed and hence no toxic effects of this compound are manifested. However, cataract is seen. Galactokinase deficiency is reported to be 1 in 40,000 births.

**METABOLISM OF ALCOHOL**

Alcohol absorption starts from the stomach itself, but most of it is absorbed by intestine. Only 1% of the ingested alcohol is excreted through the lungs or urine. Major fraction of the alcohol is oxidized in the liver.

1. **Alcohol Dehydrogenase (ADH)**

   It is an NAD⁺ dependent **cytoplasmic** enzyme that oxidizes ethanol to acetaldehyde (Fig. 10.12).
Alcohol dehydrogenase is a dimer and has 6 iso-enzymes. In some individuals, the enzyme is mutated. This mutation rate is more in Orientals. In such individuals, alcohol metabolism is slower and even small quantity of alcohol may produce symptoms of intoxication. The enzyme was identified by Bateilli and Stern in 1909.

2. Aldehyde Dehydrogenase
Acetaldehyde is further oxidized to acetate by a mitochondrial NAD+ dependent enzyme (Fig. 10.12). The acetate is then converted to acetyl CoA. The activity of alcohol dehydrogenase is more than aldehyde dehydrogenase. So acetaldehyde accumulates in liver. Aldehyde is toxic, which in excess may lead to cell death. The activity of aldehyde dehydrogenase is less in Indians, when compared to Europeans.

3. Microsomal Ethanol Oxidizing System (MEOS)
It is another mechanism of detoxification of alcohol. It is cytochrome P450 dependent and is inducible. This accounts for metabolic tolerance of alcohol observed in chronic alcoholics.
Ethanol can be oxidized in liver microsomes to acetaldehyde by a mixed function oxidase. The electron donors are ethanol and NADPH by which O2 is reduced to water.
\[
\text{CH}_3\text{CH}_2\text{OH} + \text{NADPH} + \text{H}^+ + 2\text{O}_2 \rightarrow \text{CH}_3\text{CHO} + 2\text{H}_2\text{O}_2 + \text{NADP}^+
\]
MEOS is part of the superfamily of cytochrome P450, all of which catalyze similar reactions. About 10 gene families and 100 different cytochrome P450 molecules are available. The isoenzyme with highest activity towards ethanol is designated CYP2E1 (2 refers to the gene family, E refers to the subfamily and 1 refers to the particular enzyme). CYP2E1 has higher Km for ethanol than Class I ADH (11 mM). When the ethanol consumption is high, higher proportion is metabolized by MEOS. Other CYP isoenzymes also metabolize alcohol and MEOS refers to the combined oxidizing activity of all these.

Biochemical Alterations in Alcoholism
Both the oxidation steps of alcohol produces NADH, resulting in a high NADH/NAD+ ratio. As a result, several metabolic adaptations occur.

1. In the cytoplasm, the high NADH level favors conversion of pyruvate to lactate, leading to lactic acidosis.
2. Deficiency of pyruvate leads to inadequate formation of oxaloacetate. This results in depression of gluconeogenesis, leading to hypoglycemia.
3. Reduced oxaloacetate, decreased pyruvate and high NADH level causes suppression of TCA cycle. So Acetyl CoA is accumulated, which favors ketogenesis.
4. Increased level of acetyl CoA causes increased fatty acid synthesis; but fatty acid is not oxidized. So fat is accumulated in liver, resulting in fatty liver and steatosis.
5. Alcohol also increases the release of ROS, leading to mitochondrial damage and apoptosis.
6. Lactic acidosis causes decreased excretion of uric acid, resulting in acute attack of gout (See Chapter 39).
7. Alcohol causes CNS depression by inhibiting excitatory receptors (N-methyl aspartate receptors) and by potentiating inhibitory neurotransmitter (GABA) receptors.

Chronic Alcoholism

A. Alcoholism and liver
1. Accumulation of fat in liver cells leading to fatty liver. Accumulated toxic effect of acetaldehyde leads to cellular death.
2. This is followed by replacement by fibrous tissue. Fibrosis of liver is called Cirrhosis. When liver functions are reduced (See chapter 26) hepatic coma results.
3. Elimination rates of ethanol vary among individuals and populations. Susceptibility to alcohol is a complex function of genetics and socioeconomic factors. Possession of an allele that encodes a relatively fast ADH (alcohol dehydro-genase) is associated with a decreased susceptibility. A single amino acid substitution (Glu487 by Lys) produces a variant ALDH (Aldehyde dehydrogenase) with high Km (260 times) and low affinity for acetaldehyde. Vmax is also reduced 10 times. This enzyme is very inactive. Homozygotes for this variant afford absolute protection against alcoholism.
4. Five per cent of all deaths in India are due to liver diseases, for which the most important culprit is alcohol. In India, chronic alcoholism is the most leading cause for morbidity and consequent loss of man hours. The activity of mitochondrial aldehyde dehydrogenase is less in Asians compared to western population. Hence Indians are more prone for alcoholic cirrhosis.

B. Alcoholism and Nervous System
In chronic alcoholics, the brain ventricles are enlarged, neurons are lost, neuro-degenerative changes set in the memory is affected. In alcoholics, combined thiamine deficiency leads to Wernick's disease. Aldehyde inhibits pyridoxal phosphate; hence neuritis is very common in alcoholics (See Chapter 34).

C. Alcohol and Cardiovascular System
There are reports stating that mild alcohol intake (red wine less than 20 mg per day) will marginally elevate HDL, and hence reduce the risk for myocardial infarction to a certain extent. But this minor benefit on heart, far outweighs the deleterious effects of alcohol on liver.

D. Alcohol and Lungs
A small percent of alcohol is eliminated through lungs. So, lungs also share the deleterious effects of alcohol. Pneumonitis is often seen in chronic alcoholism.

E. Laboratory Findings in Chronic Alcoholism
i. Increase in serum levels of gamma-glutamyl transferase (GGT) and alanine transaminase (ALT) (See Chapter 23).
ii. Decrease in aldehyde dehydrogenase activity (in liver cells and RBCs) is the best marker for alcohol abuse.
iii. Desialylated transferrin level in blood is a highly sensitive marker for chronic alcohol abuse.

METABOLISM OF AMINO SUGARS
The amino sugars, N-acetyl glucosamine, N-acetyl galacto-samine and N-acetyl neuraminic acid are synthesized from fructose-6-phosphate. The amino group is derived from amide group of glutamine. The reaction is catalyzed by an amido transferase. This is irreversible; it is the rate limiting step in amino sugar synthesis.

The glucosamine-6-phosphate is then acetylated by acetyl CoA to form N-acetyl glucosamine-6-phosphate. The active form of amino sugar, namely, UDP-N-acetyl glucosamine is formed from N-acetyl glucosamine-1-phosphate, with the help of a mutase and a pyrophosphorylase. It is then epimerized to galactose derivative.

![Fig. 10.13. Synthesis of N-acetyl neuraminic acid (NANA)](image)

Both these are used for synthesis of glycosaminoglycans and gangliosides. Mannose (6C) and pyruvate (3C) combines to form 9C compound, N-acetyl neuraminic acid (NANA). The steps are outlined in Figure 10.13.

Lysosomal storage disorders due to defective degradation of GAG are called Mucopolysaccharidoses. The major features of different types of such disorders are given in Table 10.1. All amino sugars are derived from glucose (Fig. 10.14).

GLYCOPROTEINS
Glycobiology is the study of the sugars in health and disease. The glycome is the entire component of sugars in the cell. Glycomics is the comprehensive study of the carbohydrates in its entire aspects. Lectins (See Chapter 4) can be used to isolate and purify glycoproteins.

Glycoproteins have a protein backbone to which oligosaccharide groups are attached. Only 8 monosaccharides are commonly found in such side chains; some of them will

P= phosphate; G= glucose; F= fructose; gluN= glucosamine; Neura = neuraminic; NAc = N-acetyl; UDP = uridine diphosphate; GAG = glycosaminoglycans
be further acetylated or sulfated. These are glucose, galactose, mannose, galNAc, gluNAc, xylose, fucose and N-acetyl neuraminic acid (sialic acid).

Depending on the sialic acid content, the electric charges are also varied. Glycoproteins are widely distributed in tissues. All plasma proteins are glycoproteins. Examples are given in Table 10.3.

In glycoproteins, the carbohydrate groups are attached to the polypeptide chain by the following types of linkages:

a. Through the amide group of asparagine to N-acetyl glucosamine and Glucuronic acid (N-glycosidic linkages) (The biosynthesis of N-linked glycoproteins involves Dolichol phosphate. Dolichol is a polyisoprenol, containing about 20 repeating isoprenoid units). Dolichol is activated to Dol-P-P-GluNAc; GluNAc to dolichol-phosphate.

b. Through hydroxyl group of serine, threonine, hydroxylysine and hydroxyproline to N-acetyl glucosamine or galactose or xylose (beta-O-glycosidic linkages). Glycosylation occurs in golgi bodies and only proteins that are glycosylated and properly folded are exported.

c. Linked to carboxyl terminal amino acid of the protein via phosphoryl-ethanolamine, which is linked to a phosphatidyl inositol, which in turn is linked to a glucosamine in the glycan group. This is called glycosyl phosphatidyl inositol (GPI) linkage. Some proteins are anchored to the plasma membrane by glycosyl phosphatidyl inositol (GPI) linked proteins.

There can be many (usually 20-30) oligosaccharide chains attached to a single protein. Each sugar chain may range from 1 to 20 in length.

Enzymatic addition of specific carbohydrate unit on the protein is called glycosylation, while non-enzymatic spontaneous addition is called glycation. Proteins with identical amino acid sequences, but having different oligosaccharide sequences are called glycoforms.

The glycoproteins function as recognition sites on cell surfaces. The carbohydrate containing uppermost layer of plasma membrane is known as glycocalyx.

Blood Group Substances (Antigens)
The RBC membrane contains several antigenic substances, based on which persons are classified into different blood groups. More than 160 different antigens are known. Of these ABO system and Lewis system are known to involve glycoproteins. ABO system is associated with 3 blood group substances on RBCs designated A, B and H antigens. The H antigen is the basic structure. It has the following structure:

\[
\text{Fucose—Gal—GalNAc—Protein}
\]

The RBCs carrying such H antigen are denoted as blood group O. A and B antigens differ from this in having additional sugar residues.

A antigen: – Fucose—Gal—GalNAc—Protein

| GluNAc

B antigen: – Fucose—Gal—GalNAc—Protein

| Gal

The H locus codes for fucosyl transferase. In a person belonging to blood group A, N-acetyl-galactosaminyl transferase is present. In group B person, galactosyl transferase is seen. Lack of both leads to blood group O, while AB persons have both enzymes.

Selectins, Integrins and ICAMs
Leukocytes generally pass over endothelial surface of blood vessels. When necessity arises, leukocytes can attach over the endothelial surface, then pass through junctions between endothelial cells, so as to reach extravascular compartment. This attachment involves interaction between selectins or integrins on the leukocytes and ICAM (intracellular adhesion molecule) present on the endothelial cells. The selectins are glycoproteins and the corresponding receptors on the endothelial surface will have lectin type domains. There are different types of selectins and integrins.

Proteoglycans
Proteoglycans are complexes of glycosaminoglycans (GAG) and proteins. As the carbohydrate content is increased, viscosity is increased and solubility is decreased. The carbohydrate content of mucins is generally more than 50%. Mucus consists of 5-10% of mucins. These monomers are further linked together by disulphide linkages, to form oligomers. Mucins will form a protective barrier on epithelial surfaces. They are also found in secretions of the gastrointestinal, respiratory and urogenital tract. The GAGs containing repeating disaccharide units are covalently bound to the peptide chain to form proteoglycans. Structures of the repeating sugar units are shown in the end of Chapter 6. The different GAGs, found in different tissues are shown in Table 10.4.
Biosynthesis of Glycoproteins

The biosynthesis of GAG is taking place in endoplasmic reticulum and Golgi bodies, with the help of specific glycosyl transferases. As the protein is synthesized at the endoplasmic reticulum, these carbohydrate units are added one by one. Certain amino acid sequences in the protein will code for the attachment of the glycans; specific enzymes will add the glycans sequentially. This addition needs activation of sugar; activation is in the form of corresponding nucleotide sugar. For example, UDP-glucose is utilized for addition of glucose on the protein backbone. UDP glucose is produced by the following reaction:

\[ \text{UTP} + \text{Glucose-1-phosphate} \rightarrow \text{UDP-glucose} + \text{pyrophosphate} \]

The enzyme is UDP-glucose pyrophosphorylase.

There are carrier systems (transporters) to transport nucleotide sugars across Golgi membrane. Termination of the oligosaccharide chain occurs following sulfation of the sugar residues.

The glycoproteins having mannose-6-P as the end residue will be directed to lysosomes. Mannose phosphate acts as the tag to deliver such glycoproteins into lysosomes. Defect in this correct tagging will lead to defective targeting. See I-cell disease, described in Chapter 41.

Calnexin and Calreticulin are proteins present in the endoplasmic reticulum membrane that act as chaperones for correct folding of glycoproteins, and also preventing aggregation of glycans. Only the correctly folded glycoproteins are secreted out of endoplasmic reticulum.

Congenital Disorders of Glycosylation (CDG)

These are emerging group of autosomal recessive disorders. They are multisystem disorders, mostly affecting CNS, with mental retardation. At least 15 distinct disorders in this group have been reported.

Leukocyte Adhesion Deficiency (LAD)

It is due to mutation affecting Golgi fucose transporter. So, selectins are not correctly glycosylated, resulting in sluggish activity of leukocytes.

Paroxysmal Nocturnal Hemoglobinuria (PNH)

There is somatic mutation in PIG (phosphatidyl inositol glycan) gene in hematopoietic cells. The product of this gene is necessary for GPI linkage. So, GPI linked proteins are deficient on the RBCs. During sleep, there is a slight drop in pH of blood, causing mild RBC lysis by complement factors, which leads to excretion of hemoglobin in urine. Normal persons can withstand this lysis with the help of GPI linked proteins, termed decay accelerating factor (DAF).

Rheumatoid Arthritis

There is altered glycosylation of circulating immunoglobulin G, these are aglycosyl IgG molecules. These will activate complement system, causing chronic inflammation of synovial membranes of joint cavities.

Viruses

Many viruses will attach on human cells through specific glycoproteins. HIV virus (causing AIDS), attaches on lymphocytes by means of a surface glycoprotein (gp120) of the virus (See Chapter 50). Influenza virus attaches by hemagglutinin (H). So, neuraminidase inhibitors are used as antiviral drugs against H1N1. Helicobacter pylori, causing peptic ulcer, binds through two different glycoproteins present on the epithelial cells of stomach. Plasmodium falciparum (parasite causing malaria) attaches to human cells by a glycoprotein on the surface of the parasite.

Catabolism of Glycoproteins

The catabolism is by hydrolases which are bond specific. Deficiency of these enzymes would result in marked accumulation of substrates (Table 10.1). The half life of many proteins in circulation is determined by glycosylation. This is a potential area for therapeutics, where carbohydrate side chains are removed (asialo glycation), and the half-life of proteins used as drugs can be prolonged.

Mucopolysaccharidoses

These are a group of inborn errors of metabolism characterised by excessive intralysosomal accumulation of GAG in various tissues. They are progressive disorders. The clinical manifestations include coarse facial features, thick skin and corneal opacity due to accumulation of GAG. Mental retardation, growth deficiency and skeletal dysplasia are also seen due to defective formation of ground substances. In general, defective degradation of heparan sulphate leads to mental retardation predominantly whereas accumulation of other GAGs leads to mesenchymal abnormalities.

A characteristic finding is the excessive excretion of any one of the GAGs in urine. All these diseases are inherited as autosomal recessive traits, except Hunter's disease which is X-linked (Table 10.1). The inborn errors associated with carbohydrate metabolism, are shown in Table 10.2.
Metabolism of Fatty Acids

CHAPTER 11: Metabolism of Fatty Acids

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Digestion of lipids
2. Absorption of lipids
3. Chylomicrons
4. Beta oxidation of fatty acids
5. Oxidation of odd chain fatty acids
6. Alpha oxidation
7. Omega oxidation
8. De novo synthesis of fatty acids
9. Synthesis of triglycerides
10. Metabolism of adipose tissue
11. Fatty liver and lipotropic factors
12. Ketogenesis and ketolysis

DIGESTION OF LIPIDS
The major dietary lipids are triacyl glycerol, cholesterol and phospholipids. The average normal Indian diet contains about 20-30 g of lipids per day. Western diet generally contains two or three times more than this quantity.

Digestion in Stomach
The lingual lipase from the mouth enters stomach along with the food. It has an optimum pH of 2.5-5). The enzyme, therefore, continues to be active in the stomach. It acts on short chain triglycerides (SCT). SCTs are present in milk, butter and ghee. The action of lingual lipase is observed to be more significant in the newborn infants. Gastric lipase is acid stable, with an optimum pH around 5.4. It is secreted by chief cells, the secretion is stimulated by gastrin. Up to 30% digestion of triglycerides occurs in stomach.

Digestion in Intestines
Emulsification is a prerequisite for digestion of lipids. The lipids are dispersed into smaller droplets; surface tension is reduced; and surface area of droplets is increased. This process is favored by:
1. Bile salts (detergent action)
2. Peristalsis (mechanical mixing)
3. Phospholipids

Bile Salts are Important for Digestion of Lipids
The bile salts present in the bile (sodium glycocholate and sodium taurocholate) lower surface tension. They emulsify the fat droplets. The emulsification increases the surface area of the particles for enhanced activity of enzymes (Fig. 11.2).

Lipolytic Enzymes in Intestines
1. Pancreatic lipase with Co-lipase
2. Cholesterol esterase

The bile (pH 7.7) entering the duodenum serves to neutralise the acid chyme from the stomach and provides a pH favorable for the action of pancreatic enzymes. A list of physiologically important lipases is shown in Table 11.1.

Fig. 11.1. Complete hydrolysis of triglyceride. In the intestines, generally fats are only partially hydrolysed
Digestion of Triglycerides

1. **Pancreatic lipase** can easily hydrolyse the fatty acids esterified to the 1st and 3rd carbon atoms of glycerol forming 2-monoacylglycerol and two molecules of fatty acid (Fig. 11.1).

2. Then an **isomerase** shifts the ester bond from position 2 to 1. The bond in the 1st position is then hydrolysed by the **lipase** to form free glycerol and fatty acid (Fig. 11.1).

3. The major end products of the digestion of TAG are 2-MAG (78%), 1-MAG (6%), glycerol and fatty acids (14%). Thus digestion of TAG is partial (incomplete).

4. **Cholesterol** ester may be hydrolysed to free cholesterol and fatty acid. The action of **phospholipase** A2 produces lysophospholipid and a fatty acid (see Fig. 7.8).

**Co-lipase**

The binding of co-lipase to the triacyl glycerol molecules at the oil water interface is obligatory for the action of lipase. The co-lipase is secreted by the pancreas as an inactive zymogen (molecular weight 11,000). It is activated by trypsin.

**Fig. 11.2.** Action of bile salts. The hydrophobic portions of bile salts intercalate into the large aggregated lipid, with the hydrophilic domains remaining at the surface. This leads to breakdown of large aggregates into smaller and smaller droplets. Thus, the surface area for action of lipase is increased.

**ABSORPTION OF LIPIDS**

**Absorption of Long Chain Fatty Acids**

Long chain fatty acids (chain length more than 14 carbons) are absorbed to the lymph and not directly to the blood. The theory proposed by Bergstrom (Nobel Prize, 1982) has the following steps.

1. **Mixed Micelle Formation**
   i. The products of digestion, namely 2-mono-glycerides, long chain fatty acids, cholesterol, phospholipids and lysophospholipids are incorporated into molecular aggregates to form **mixed micelle** (Fig. 11.3). The micelles are spherical particles with a hydrophilic exterior and hydrophobic interior core (Fig. 11.3).
Due to their detergent action, the bile salts help to form micellar aggregates (Fig. 11.2).

ii. Micellar formation is essential for the absorption of fat-soluble vitamins such as vitamin A, D and K.

iii. The micelles are aligned at the microvillous surface of the jejunal mucosa. Fatty acids, 2-MAG and other digested products passively diffuse into the mucosal cell (Fig. 11.4).

2. Enterohepatic Circulation of Bile Salts
The bile salts are left behind which are mostly reabsorbed from the ileum and returned to the liver to be re-excreted (enterohepatic circulation). About 98% of dietary lipids are normally absorbed.

3. Re-esterification Inside the Mucosal Cell
i. Once inside the intestinal mucosal cell, the long chain fatty acids are re-esterified to form triglycerides (Fig. 11.5).

ii. The fatty acids are first activated to fatty acyl CoA by the enzyme, acyl CoA synthetase or thiokinase (Fig. 11.9). This needs lysis of two high energy bonds.

iii. Two such activated fatty acids react with monoacyl glycerol (MAG) to form the triglyceride. Majority of molecules follow this MAG pathway (Figs 11.4 and 11.5).

iv. Free glycerol absorbed from intestinal lumen directly enters into the bloodstream. So free glycerol is not available for re-esterification. But the cells can convert glucose to glycerol phosphate, and then add 3 molecules of acyl groups to synthesize TAG.

3. Chylomicrons
The TAG, cholesterol ester and phospholipid molecules along with apoproteins B48, and apo-A are incorporated into chylomicrons (Fig. 11.6). The chyle (milky fluid) from the intestinal mucosal cells loaded with chylomicrons are transported through the lacteals into the thoracic duct and then emptied into lymph circulation (Fig. 11.5). The serum may appear milky after a high fat meal (postprandial...
lipemia) due to the presence of chylomicrons in circulation. Normally the lipemia clears within a few hours by the uptake of chylomicrons by tissues. The major steps of lipid absorption are shown in Box 11.1.

4. SCFA Absorption is Different
   i. Short chain fatty acids (SCFA) (seen in milk, butter, ghee) and medium chain fatty acids (MCFA) (in coconut oil and mother’s milk) do not need re-esterification.
   ii. They can directly enter into blood vessels, then to portal vein, finally to liver where they are immediately utilised for energy (Fig. 11.5).
   iii. Their absorption is rapid. They are better absorbed than long chain fatty acids. Special features in digestion and absorption of medium chain fatty acids are given in Table 13.1.

5. Abnormalities in Absorption of Lipids
   1. Defective digestion: In steatorrhea, daily excretion of fat in feces is more than 6 g per day. (Greek word, "stear", means fat). It is due to chronic diseases of pancreas. In such cases, unsplit fat is seen in feces (Box 11.2).
   2. Defective absorption: On the other hand, if the absorption alone is defective, most of the fat in feces may be split fat, i.e. fatty acids and monoglycerides (Box 11.2). Defective absorption may be due to diseases.

Box 11.2. Absence of Digestive Juices
   1. In pancreatic deficiency: Steatorrhea; unsplit fat is present in stools.
   2. When bile is not available: Absorption is defective; split fat is present in stools; defective absorption of vitamin K leads to prolonged prothrombin time.

2-A. Celiac disease, sprue, Crohn’s disease.
2-B. Surgical removal of intestine.
2-C. Obstruction of bile duct: This may be due to gall stones, tumors of head of pancreas, enlarged lymph glands, etc. The result is deficiency of bile salts. In such cases, triglycerides with short chain and medium chain fatty acids (SCT and MCT) are digested and absorbed properly, because they do not require micellisation for absorption. Since milk fat and coconut oil are made up of MCT, they are therapeutically useful in malabsorption syndromes.

3. Chyluria: There is an abnormal connection between the urinary tract and lymphatic drainage system of the intestine. Urine appears milky due to lipid droplets. Chylothorax can result from an abnormal connection between the pleural cavity and thoracic duct.

6. Fate of Chylomicrons
   i. The absorbed (exogenous) triglycerides are transported in blood as chylomicrons. They are taken up by adipose tissue and liver.
   ii. Liver synthesizes endogenous triglycerides. These are transported as VLDL (very low density lipoproteins) and are deposited in adipose tissue.
   iii. During starvation states, triglycerides in adipose tissue are hydrolyzed to produce free

---

**Box 11.1. Six Steps of Lipid Absorption**

1. **Minor digestion** of triacylglycerols in mouth and stomach by lingual (acid-stable) lipase.
2. **Major digestion** of all lipids in the lumen of the duodenum/jejunum by pancreatic lipolytic enzymes.
3. **Bile acid** facilitated formation of mixed micelles.
4. **Passive absorption** of the products of lipolysis from the mixed micelle into the intestinal epithelial cell.
5. **Reesterification** of 2-monooacylglycerol with free fatty acids inside the intestinal enterocyte.
6. **Assembly** of chylomicrons containing Apo B48, triacylglycerol, cholesterol esters and phospholipids and export from intestinal cells to the lymphatics.

**Fig. 11.6. Summary of utilization of fat**
fatty acids. In the blood, they are transported, complexed with albumin. These free fatty acids are taken up by the cells, and are then oxidised to get energy. A summary of lipid transport is shown in Figure 11.6.

**BETA OXIDATION OF FATTY ACIDS**

This process is known as beta oxidation, because the oxidation and splitting of two carbon units occur at the beta-carbon atom. The oxidation of the hydrocarbon chain occurs by a sequential cleavage of two carbon atoms (Fray Knoop, 1904).

**Preparative Steps for Beta Oxidation**

The co-enzyme A is a complex molecule containing B complex vitamin pantothenic acid and a molecule of beta mercapto ethanolamine; this SH group forms thioester bond in acyl CoA (Fig. 11.7). To emphasise the function of the SH group, the CoA is sometimes written as CoA-SH.

**Preparative Step 1: Activation of Fatty Acids**

Fatty acids are activated to their co-enzyme A (CoA) derivative. This activation is taking place in cytoplasm. ATP is hydrolysed to AMP and PPi and the energy from hydrolysis of PPi drives the reaction forward. Thus two high energy bonds are utilised in this reaction.

The enzyme is a thio kinase or fatty acyl CoA synthetase (step 0, Fig. 11.9). Acetyl group and acyl groups are different; see Box 11.3.

Three different enzymes, one each for short chain, medium chain and long chain fatty acids have been identified. Small chain fatty acids may also be activated by thio phosphorase enzyme, using succinyl CoA (see under ketone bodies).

**Box 11.3. Acetyl and Acyl Groups are Different**

| Acetyl CoA | is the combination of acetate or acetic acid (2 carbon unit) with Co-enzyme A. |
| Acyl CoA | means acyl group (any fatty acid, C4 to C26 in length) combined with Co-enzyme A. |

**Preparative Step 2: Role of Carnitine**

Fatty acids are activated in the cytoplasm; but the beta oxidation is in mitochondria. So transport of fatty acids through the mitochondrial membrane is essential. The long chain fatty acyl CoA cannot pass through the inner mitochondrial membrane. Therefore a transporter, carnitine is involved in transfer of fatty acids. Carnitine is beta-hydroxy-gamma-trimethyl ammonium butyrate, \((CH_3)_2-\text{N}^+\text{CH}_2\text{CHOH-CH}_2\text{COOH}\).

It is synthesised from lysine and methionine in liver and kidney.

**Preparative Step 3: Carnitine Acyl Transferase**

The enzyme carnitine acyl transferase-I (CAT-I) will transfer the fatty acyl group to the hydroxyl group of carnitine to form acyl carnitine (Fig. 11.8) The reaction occurs on the cytosolic side of inner mitochondrial membrane.

**Preparative Step 4: Translocase**

A protein translocase will carry the acyl carnitine across the membrane to the matrix of mitochondria. On the matrix side of the membrane another enzyme, carnitine acyl transferase-II (CAT-II) will transfer the acyl group back to co-enzyme A molecule (Fig. 11.8). Carnitine is returned to the cytosolic side by the translocase.

---

**Clinical Applications**

1. Medium chain and short chain fatty acids do not require carnitine for transport across the inner mitochondrial membrane. So medium chain and short chain fatty acids are easily oxidised.

2. **Carnitine deficiency** is reported in preterm infants, in whom impaired fatty acid oxidation is noticed. So more glucose is utilised, resulting in episodes of hypoglycemia.

3. **Deficiency of translocase**: It leads to defective metabolism of long chain fatty acids. In this condition, muscle cramps are precipitated by fasting, exercise and high fat diet.

4. Inherited **CPT-I deficiency** affects only the liver, resulting in reduced fatty acid oxidation and ketogenesis, with hypoglycemia. **CPT-II deficiency** affects primarily skeletal muscle and, when severe, the liver. The sulfonylurea drugs (glibenclamide and tolbutamide), used in the treatment of type 2 diabetes mellitus, reduce fatty acid oxidation and, therefore, hyperglycemia by inhibiting CPT-I.

**Beta Oxidation Steps**

The next 4 reactions are sequentially repeated for complete oxidation of fatty acids. After one round of four metabolic steps, one acetyl CoA unit is split off and acyl CoA with 2 carbon atoms less is generated. This would undergo the same series of reactions again until the fatty acid is completely oxidised.

**Step 1: FAD Linked Dehydrogenase**

The fatty acyl CoA is dehydrogenated to a trans enoyl CoA with the FAD accepting the hydrogen atoms (step 1, Fig. 11.9). FADH₂ when oxidised in electron transport chain will produce **1.5 ATP** molecules.

**Step 2: Hydration**

This is catalysed by an enoyl CoA hydratase (step 2, Fig. 11.9). This step forms a beta-hydroxy fatty acyl CoA. The L isomer alone is formed during the hydration of the trans double bond.

**Step 3: NAD⁺ Dependent Dehydrogenase**

The beta-hydroxy fatty acyl CoA is again oxidised to form beta-keto fatty acyl CoA (step 3, Fig. 11.9). This dehydrogenase acts only on L isomer. The NADH when oxidised in electron transport chain will generate **2.5 ATPs**.

**Step 4: Cleavage**

The beta-keto fatty acyl CoA now undergoes thiolysis cleavage, splitting off a molecule of acetyl CoA and once again generating acetyl CoA that is ready to enter the Krebs cycle. This cycle can be repeated for many rounds, with each round reducing the carbon chain by 2 units through reactions that generate ATP and are dependent on NAD+ and FAD.
CoA and leaving behind a fatty acid with 2 carbon atoms less (step 4, Fig. 11.9).

**Further Cycles**
The newly formed fatty acyl CoA will sequentially undergo further cycles of steps 1, 2, 3 and 4 of beta-oxidation until the fatty acid is completely converted to acetyl CoA (Fig. 11.10). A summary is shown in Box 11.4.

**Energetics of Beta Oxidation (ATP Yield)**

**Palmitic acid** (16 C) needs 7 cycles of beta oxidation (Fig. 11.10). So, it gives rise to 8 molecules of acetyl CoA. Every molecule of acetyl CoA when oxidised in the TCA cycle gives 10 molecules of ATP (Box 11.4). Each molecule of FADH₂ produces 1.5 molecules of ATP and each NADH generates 2.5 molecules of ATP, when oxidised in the electron transport chain. Hence the energy yield from one molecule of palmitate may be calculated as:

\[
\begin{align*}
8 \text{ acetyl CoA} & \times 10 = 80 \text{ ATP} \\
7 \text{ FADH}_2 & \times 1.5 = 10.5 \text{ ATP} \\
7 \text{ NADH} & \times 2.5 = 17.5 \text{ ATP} \\
\text{Gross total} & = 108 \text{ ATP} \\
\text{Net yield} & = 108 - 2 = 106 \text{ ATP}
\end{align*}
\]

(In the initial activation reaction, the equivalents of 2 high energy bonds are utilised). The efficiency of beta oxidation is about 33%. The differences in oxidation of unsaturated fatty acids are shown in Chapter 13.

**Important Note:** In the previous editions of this textbook, calculations were made assuming that NADH produces 3 ATPs and FADH generates 2 ATPs. This will amount to a net generation of 129 ATP per palmitate molecule. Recent experiments show that these old values are over-estimates, and net generation is only 106 ATPs.

**Regulation of Beta Oxidation**

i. The availability of free fatty acid (FFA) regulates the net utilisation through beta oxidation.

ii. The level of FFA, in turn, is controlled by glucagon:insulin ratio. Glucagon increases FFA level and insulin has the opposite effect.

iii. CAT-I is the regulator of entry of fatty acid into mitochondria. Malonyl CoA inhibits CAT-I activity. Thus during *de novo* synthesis of fatty acid, the beta oxidation is inhibited.

**Defects in Beta Oxidation**

Abnormalities in transport of fatty acids into mitochondria and defects in oxidation can lead to deficient energy production by oxidation of long chain fatty acids. Common features are hypoketotic hypoglycemia, hyperammonemia, skeletal muscle weakness and liver diseases.
Acyl carnitine accumulates when the transferase or translocase is deficient. Dietary supplementation of carnitine has been found to improve the symptoms in some cases.

Organic Acidurias
They are disorders of metabolism of fatty acids, branched chain and aromatic amino acids and citric acid cycle. The incidence of "medium chain acyl CoA dehydrogenase deficiency" is about 1 in 2,500 live births, and is the second most common inborn error of metabolism (WHO, 2003). They are all characterised by the accumulation of organic acids in body tissues and their excretion in urine. The patients present with acidosis, vomiting, convulsions and coma. The children often die in infancy; in case they survive, there is severe mental and physical retardation. Diagnosis is confirmed by showing the presence of organic acids in urine by chromatography. Dietary restriction, cofactor therapy and substrate removal are the general lines of management. Examples of these disorders are given in Table 11.2.

OXIDATION OF ODD CHAIN FATTY ACIDS
The odd chain fatty acids are oxidised exactly in the same manner as even chain fatty acids. However, after successive removal of 2-carbon units, at the end, one 3-carbon unit, propionyl CoA is produced.

Fate of Propionyl CoA
1. Carboxylase: Propionyl CoA is first carboxylated to D-methyl malonyl CoA by a biotin dependent carboxylase. Biotin is a member of vitamin B complex group. One molecule of ATP is utilised to supply energy (step 1, Fig. 11.11).
2. Racemase: Then racemase acts upon D-methyl malonyl CoA to give L-methyl malonyl CoA (step 2, Fig. 11.11).
3. Mutase: Then the L-methyl malonyl CoA is rearranged to form succinyl CoA by L-methyl malonyl CoA mutase. The reaction needs vitamin B₁₂ co-enzyme (step 3, Fig. 11.11).
4. The succinyl CoA then enters TCA cycle, finally converted to oxaloacetate, and is used for gluconeogenesis.
5. Propionyl CoA is also derived from the metabolism of valine and isoleucine (see Chapter 16).

Propionate is Gluconeogenic
Ordinary fatty acids are cleaved to acetyl CoA units which on entering the Krebs cycle are completely oxidised to CO₂, and hence as a general rule, fatty acids cannot be used for gluconeogenesis. However propionate is entering into the citric acid cycle at a point after the CO₂ elimination steps, so propionate can be channelled to gluconeogenesis. Thus 3 carbon units from odd carbon fatty acids are gluconeogenic. Cow’s milk contains significant quantity of odd chain fatty acids.

Inborn Errors of Propionate Metabolism
1. Propionyl CoA carboxylase deficiency: It is characterised by propionic acidemia, keto acidosis, and developmental abnormalities.
2. Methyl malonic aciduria: Some patients respond to treatment with pharmacological doses of B₁₂. This group will have defective formation of adenosyl B₁₂ with deficient mutase activity. The second type will not respond to cyanocobalamin and has deficiency of the enzyme racemase or mutase. The methylmalonate affects the metabolism of brain leading to mental retardation in these cases.

Alpha Oxidation
It is a process by which fatty acids are oxidised by removing carbon atoms, one at a time, from the carboxyl end. The process is important in brain.
The fatty acid does not need activation. Hydroxylation occurs at the alpha-carbon atom. It is then oxidized to alpha-keto acid. The keto acid then undergoes decarboxylation yielding a molecule of CO₂ and a fatty acid with one carbon atom less. This process occurs in the endoplasmic reticulum, does not require CoA, but does not generate energy. Some fatty acids undergo alpha hydroxylation in peroxisomes also.

Alpha-oxidation is mainly used for fatty acids that have a methyl group at the beta-carbon, which blocks beta oxidation. A major dietary methylated fatty acid is phytanic acid (Fig. 11.12). It is derived from phytol present in chlorophyll, milk and animal fats.

**Refsum's Disease**

It is a metabolic error due to lack of alpha-hydroxylase (phytanic acid oxidase) so that alpha oxidation does not occur and phytanic acid accumulates in the tissues. The patient presents with severe neurological symptoms, polyneuropathy, retinitis pigmentosa, nerve deafness and cerebellar ataxia. Regressions of symptoms are observed with restricted dietary intake of phytanic acid. Milk is a good source of phytanic acid, which may be avoided.

**Infantile Refsum's Disease**

It is a peroxisomal disorder, similar to Zellweger syndrome and adrenoleukodystrophy (see Chapter 41). Hence phytanic acid accumulates along with VLCFA. Children do not survive long.

**Omega Oxidation**

It is a minor pathway taking place in microsomes, with the help of hydroxylase enzymes involving NADPH and cytochrome P-450. The CH₃ group is converted to CH₂OH and subsequently oxidised with the help of NAD⁺ to a COOH group to produce dicarboxylic acids. ω-oxidation becomes important when β-oxidation is de’ citive and dicarboxylic acids (6C and 8C acids) are excreted in urine causing dicarboxylic aciduria. Peroxisomal oxidation is described in Chapter 13, under VLCFA.

**DE NOVO SYNTHESIS OF FATTY ACIDS**

The process of fatty acid synthesis was studied by Feodor Lynen, who got Nobel prize in 1964. The pathway is referred to as Lynen’s spiral. It is not a reversal of oxidation. Important differences in

**Fig. 11.12. Phytanic acid**

**Fig. 11.13. Transfer of acetyl CoA from mitochondria to cytoplasm by malate–oxaloacetate shuttle.** 1 = citrate synthetase; 2 = ATP–citrate lyase; 3 = malate dehydrogenase; 4 = malic enzyme
synthesis and breakdown of fatty acids are given in Table 11.3.

Fatty acids are synthesized mainly by a de novo synthetic pathway operating in the cytoplasm. So it is referred to as extramitochondrial or cytoplasmic fatty acid synthase system.

The major fatty acid synthesized de novo is palmitic acid, the 16C saturated fatty acid. The process occurs in liver, adipose tissue, kidney, brain, and mammary glands.

**Transport of Acetyl CoA to Cytoplasm**
The starting material for de novo synthesis is acetyl CoA. It is formed inside the mitochondria from pyruvate. The inner membrane is not freely permeable to acetyl CoA. Hence the acetyl CoA units are delivered to the cytoplasm as citrate (Fig. 11.13). Citrate is transported from mitochondria by a tricarboxylic acid transporter. In the cytoplasm, citrate is cleaved to oxaloacetate and acetyl CoA. The enzyme is ATP citrate lyase. The oxaloacetate can return to the mitochondria as malate or pyruvate (Fig. 11.13).

**Fatty Acid Synthase (FAS) Complex**
This system exists as a multi-enzyme complex. The enzymes form a dimer with identical subunits. Each subunit of the complex is organised into 3 domains with 7 enzymes (Fig. 11.14).

**Advantages of Multi-enzyme Complex**

a. Intermediates of the reaction can easily interact with the active sites of the enzymes.
b. One gene codes all the enzymes; so all the enzymes are in equimolecular concentrations.
c. So the efficiency of the process is enhanced.

**1st Domain or Condensing Unit**
It is the initial substrate binding site. The enzymes involved are beta-keto acyl synthase or condensing enzyme (CE); acetyl transferase (AT) and malonyl trans acylase (MT) (Fig. 11.14).

**2nd Domain or Reduction Unit**
It contains the dehydratase (DH); enoyl reductase (ER); beta-keto acyl reductase (KR) and acyl carrier protein (ACP) (Fig. 11.14). The acyl carrier protein is a polypeptide chain having a phospho-pantotheine group, to which the acyl groups are attached in thioester linkage. So ACP acts like the CoA carrying fatty acyl groups (Fig. 11.14).
3rd Domain or Releasing Unit
It is involved in the release of the palmitate synthesised. It contains thio-esterase (TE) or de-acylase (Fig. 11.14).

Step 1: Carboxylation of Acetyl CoA
The first step in the fatty acid synthesis is the carboxylation of acetyl CoA to form malonyl CoA. The acetyl CoA carboxylase is not a part of the multi-enzyme complex. But it is the rate-limiting enzyme. Biotin, a member of B complex vitamins, is necessary for this reaction (step 1 in Fig. 11.15).

The enzyme is allosterically regulated, the major effectors being citrate (positive) and palmitoyl CoA (negative). The reaction is similar to carboxylation of pyruvate to form oxaloacetate.

The elongation of the fatty acid occurs by addition of 2 carbon atoms at a time. But the 2-carbon units are added as 3-carbon, malonyl units. The whole reaction sequence occurs while the intermediates are bound to ACP (acyl carrier protein).

Step 2: Three C and Two C Units are Added
2-A: The acetyl transacylase (AT in Fig. 12.14) catalyses the transfer of the acetyl group (2 carbons) to the cysteinyl SH group of the condensing enzyme (CE) of the other monomer of the fatty acid synthase complex (step 2A in Fig. 11.15).

2-B: One molecule of acetyl CoA (2 carbon) and one molecule of malonyl CoA (3 carbon) bind to the multienzyme complex. Malonyl transacylase (MT in Fig. 11.14 ) transfers the malonyl group to the SH group of the ACP of one monomer of the enzyme (step 2B in Fig. 11.15).

Step 3: Condensation
The acetyl (2C) and malonyl (3C) units are condensed to form beta-keto acyl ACP or aceto acetyl ACP (4C). During this process one carbon is lost as CO₂ (step 3 in Fig. 11.15). The enzyme is called condensing enzyme or keto acyl synthase (CE in Fig. 11.14).

Step 4: Reduction
The acetoacetyl ACP is reduced by NADPH dependent beta-keto acyl reductase (KR in Fig. 11.14) to form beta-hydroxy fatty acyl ACP (step 4 in Fig. 11.15).

Fig. 11.15. De novo synthesis of fatty acid (Lynen cycle). Steps 4 and 6 utilise NADPH.
Step 5: Dehydration
It is then dehydrated by a dehydratase (DH) to form enoyl ACP otherwise known as (alpha beta unsaturated acyl ACP) (step 5 in Fig. 11.15).

Step 6: Second Reduction
The enoyl ACP is again reduced by enoyl reductase (ER) utilizing a 2nd molecule of NADPH to form butyryl ACP (step 6 in Fig. 11.15).

Cycling of Reactions
The butyryl group (4C) is now transferred to the SH group of the condensing enzyme on the other monomer and a 2nd malonyl CoA molecule binds to the phospho-pantothenyl SH group. The sequence of reactions, namely condensation, reduction, dehydration and reduction (steps 3,4,5,6) are repeated. The cycles are repeated a total of seven times, till the 16-carbon palmitic acid is formed.

Step 7: Palmitic Acid is Released
The thio-esterase or de-acylase activity (TE) releases palmitate from the multienzyme complex (step 7 in Fig. 11.15).

The end point is Palmitic acid (16 C) in liver and adipose tissue. But in lactating mammary gland, the end products are Capric (10 C) and Lauric (12 C) acids. Mother's milk contains these medium chain fatty acids. Cow's milk contains odd numbered fatty acids.

Summary of De Novo Synthesis
The net reaction of de novo synthesis of fatty acid may be summarized as:

\[
1 \text{Acetyl CoA} + 7\text{Malonyl CoA} + 14\text{NADPH} + 14\text{H}^+ \rightarrow 1\text{Palmitate} + 7\text{CO}_2 + 14\text{NADP}^+ + 8\text{CoA} + 6\text{H}_2\text{O}
\]

Fatty acid synthesis is not an exact reversal of beta oxidation. A comparison of these pathways is given in Table 11.3.
Co-enzymes of Fatty Acid Synthesis
An important point to remember is that the co-enzyme utilised for de novo synthesis is NADPH. The sources of NADPH for fatty acid synthesis are:

1. Pentose Phosphate Pathway
This is the main source. Tissues having active lipogenesis (liver, adipose tissue, lactating mammary gland) have an active HMP shunt pathway also.

2. Malic Enzyme
Malate + NADP⁺ → Pyruvate + CO₂ + NADPH + H⁺
The reaction also helps to transfer cytoplasmic oxaloacetate to the mitochondria. For every molecule of acetyl CoA delivered to the cytoplasm, one molecule of NADPH is formed and reducing equivalents are generated in cytoplasm (Fig. 11.13).

Regulation of Fatty Acid Synthesis
1. Availability of Substrates
Fatty acid synthesis occurs when carbohydrate is abundant and the level of fatty acids is low. The availability of citrate in the cytoplasm is the most important regulatory factor producing a short-term effect.

2. Acetyl CoA Carboxylase
It is the key enzyme; citrate activates this enzyme. The citrate level is high only when both acetyl CoA and ATP are abundant. Covalent modification is another regulatory mechanism. Phosphorylation inactivates acetyl CoA carboxylase (similar to glycogen synthase under the effect of glucagon). Hence fatty acid synthesis decreases when glucose level is low. The enzyme is inhibited by palmitoyl CoA, the end product.

3. Insulin Favors Lipogenesis
Insulin enhances the uptake of glucose by adipocytes and increases the activity of pyruvate dehydrogenase, acetyl CoA carboxylase and glycerol phosphate acyl transferase (see Table 24.4). Insulin also depresses the hormone sensitive lipase (Fig. 11.16).

4. Glucagon inhibits Lipogenesis
Glucagon and epinephrine inactivate the acetyl CoA carboxylase by phosphorylating the enzyme.

Inherited Disorders
Inherited defects in the enzymes of beta oxidation and ketogenesis also lead to nonketotic hypoglycemia, coma, and fatty liver. Defects are known in long- and short chain 3-hydroxyacyl-CoA dehydrogenase, 3-Ketoacyl-CoA thiolase and HMG-CoA lyase deficiency also affect the degradation of leucine, a ketogenic amino acid. Dicarboxylic aciduria is characterized by the excretion of dicarboxylic acids and by nonketotic hypoglycemia. It is caused by a lack of mitochondrial medium-chain acyl-CoA dehydrogenase. Zellweger’s (cerebrohepatorenal) syndrome occurs in individuals with a rare inherited absence of peroxisomes in all tissues. They accumulate C26-C38 polyenoic acids in brain tissue and also exhibit a generalized loss of peroxisomal functions, e.g. impaired bile acid and ether lipid synthesis.

SYNTHESIS OF TRIGLYCERIDES (TAG)
Liver and adipose tissue are the major sites of triacylglycerol (TAG) synthesis. The TAG synthesis in adipose tissue is for storage of energy whereas in liver it is mainly secreted as VLDL and is transported to peripheral tissues. The TAG is synthesised by esterification of fatty acyl CoA with either glycerol-3-phosphate or dihydroxy acetone phosphate (DHAP) (Fig. 11.17). The glycerol part
of the fat is derived from the metabolism of glucose. DHAP is an intermediate of glycolysis. Glycerol-3-phosphate may be formed by phosphorylation of glycerol or by reduction of dihydroxy acetone phosphate (DHAP).

In adipose tissue, glycerol kinase is deficient and the major source is DHAP derived from glycolysis. However, in liver glycerol kinase is active. The fatty acyl CoA molecules transfer the fatty acid to the hydroxyl groups of glycerol by specific acyl transferases.

In addition to these two pathways, in the intestinal mucosal cells the TAG synthesis occurs by the MAG pathway. The 2-MAG absorbed is re-esterified with fatty acyl CoA to form TAG (Fig. 11.4).

Esterification of fatty acyl CoA with glycerol phosphate to form triacylglycerol occurs at a rapid rate during the fed state. Under conditions of fasting, it is seen that synthesis of triacylglycerol occurs side by side with lipolysis, since the free fatty acid level is high in plasma. The glycerol phosphate is derived from the metabolism of glucose in the fed state by channeling dihydroxy acetone phosphate, an intermediate of glycolysis. In the fasting state, the glycerol phosphate is derived from dihydroxy acetone phosphate formed during gluconeogenesis (neoglycerogenesis). The activity of the enzyme PEPCK is enhanced in liver and adipose tissue during conditions of fasting, so that glycerol phosphate is available to esterify and store the excess fatty acid mobilized.

**METABOLISM OF ADIPOSE TISSUE**

The adipose tissue serves as a storage site for excess calories ingested. The triglycerides stored in the adipose tissue are not inert. They undergo a daily turnover with new triacyl glycerol molecules being synthesized and a definite fraction being broken down.
3. Adipose Tissue and Diabetes Mellitus
Lipolysis is enhanced and high FFA level in plasma is noticed in diabetes mellitus. The insulin acts through receptors on the cell surface of adipocytes. These receptors are decreased, leading to insulin insensitivity in diabetes.

In type 2 diabetes mellitus, there is insulin resistance and the different insulin signaling pathways are affected differently. Hepatic gluconeogenesis occurs uninhibited leading to hyperglycemia. However, increased mobilization of fatty acids from adipose tissue and the persistently high free fatty acid levels in the presence of hyperinsulinemia stimulate synthesis of triacyl glycerol. The overproduction of TAG leads to increased release of VLDL from liver causing hypertriglyceridemia. The excess deposition of TAG in adipose tissue accounts for the obesity prevalent in type 2 diabetes patients.

4. Adipose Tissue and Obesity
The fat content of the adipose tissue can increase to unlimited amounts, depending on the amount of excess calories taken in. This leads to obesity. Plasma insulin level is high. But the insulin receptors are decreased; and there is peripheral resistance against insulin action. When fat droplets are overloaded, the nucleus of adipose tissue cell is degraded, cell is destroyed, and TAG becomes extracellular. Such TAG cannot be metabolically reutilised and forms the dead bulk in obese individuals.

Adipokines (Adipose Tissue Derived Hormones)
Adipokines are a group of active factors involved in maintenance of energy homeostasis as well as resistance to insulin. The important adipokines are leptin, adiponectin, resistin, TNF-alpha (tumor necrosis factor) and IL-6 (interleukin-6).

**Leptin** is a small peptide, produced by adipocytes. Leptin receptors are present in specific regions of the brain. The feeding behavior is regulated by leptin. A defect in leptin or its receptor, can lead to obesity. Leptin also prepares body to adapt for starvation. Leptin regulates energy balance and exerts an insulin sensitising effect. Decreased level of leptin increases the occurrence of obesity.

**Adiponectin** is another polypeptide which increases the insulin sensitivity of muscle and liver and exerts an anti-atherogenic effect. Low levels of adiponectin will accelerate atherosclerosis. Low levels are also observed in patients with metabolic syndrome. Leptin and adiponectin are further discussed in Chapter 36 (under obesity) and in Chapter 48.

Increased secretion of TNF-alpha and IL-6 will decrease insulin action on muscle and liver.

**White Adipose Tissue**
It is mainly concerned with energy storage. It is made up of spherical cells, with very few mitochondria. The triglycerides form the major component of white adipose tissue (about 80%) with oleic acid being the most abundant fatty acid (50%).

**Brown adipose tissue** is involved in thermogenesis. Brown adipose tissue cells are polygonal with more abundant cytoplasm. The brown color is due to the presence of numerous mitochondria. It is primarily important in newborn human beings and adult hibernating animals.

**Thermogenesis** is a process found in brown adipose tissue. Heat is liberated by uncoupling oxidation from phosphorylation. So energy is released as heat, instead of trapping it in the high energy bonds of ATP.
Liver-Adipose Tissue Axis
Role of liver in fat metabolism is shown in Box 11.4. Liver produces fatty acid and TAG (triacyl glycerol), which is transported as VLDL (very low density lipoprotein) in the blood. The fatty acids from VLDL are taken up by adipose tissue with the help of lipoprotein lipase, and stored as TAG. This neutral fat is hydrolysed by hormone sensitive lipase into NEFA, which is carried by albumin in blood. The NEFA is utilised by the peripheral tissues, excess of which can be taken up by liver cells. Thus there is a constant flux of fat molecules from liver to adipose tissue and back (Fig. 11.18).

FATTY LIVER AND LIPOTROPIC FACTORS
Fatty liver refers to the deposition of excess triglycerides in the liver cells. The balance between the factors causing fat deposition in liver versus factors causing removal of fat from liver determines the outcome.

Causes of Fatty Liver
A. Causes of fat deposition in liver
   1. Mobilization of NEFA from adipose tissue.
   2. Excess synthesis of fatty acid from glucose.

B. Reduced removal of fat from liver
   3. Toxic injury to liver. Secretion of VLDL needs synthesis of apo B-100 and apo C.
   4. Decreased oxidation of fat by hepatic cells. An increase in factors (1) and (2) or a decrease in factors (3) and (4) will cause excessive accumulation, leading to fatty liver. These pathways are summarised in Figure 11.19.

1. Excessive mobilization of fat
   The capacity of liver to take up the fatty acids from blood far exceeds its capacity for excretion as VLDL. So fatty liver can occur in diabetes mellitus and starvation due to increased lipolysis in adipose tissue (step 1 in Fig. 11.19).

2. Excess calorie intake
   Excess calories, either in the form of carbohydrates or as fats, are deposited as fat. Hence obesity may be accompanied by fatty liver (step 2 in Fig. 11.19).

3. Toxic injury to liver
   i. In toxic injury to the liver due to poisoning by compounds like carbon tetrachloride, arsenic, lead, etc. the capacity to synthesise VLDL is affected leading to fatty infiltration of liver (step 3 in Fig. 11.19).

ii. In protein calorie malnutrition, amino acids required to synthesise apoproteins may be lacking. Occurrence of fatty liver in protein energy malnutrition (PEM) may be due to defective apoprotein synthesis.

iii. Hepatitis B virus infection reduces the function of hepatic cells.

4. Alcoholism
   i. It is the most common cause of fatty liver and cirrhosis in India. The metabolism of alcohol is described in Chapter 10.

   ii. Alcohol is oxidized to acetaldehyde. This reaction produces increased quantities of NADH, which converts oxalo-acetate to malate. As the availability of oxalo-acetate is reduced, the oxidation of acetyl CoA through citric acid cycle is reduced (block in step 4 of Fig. 11.19).

   iii. So fatty acid accumulates leading to TAG deposits in liver.

5. Nonalcoholic Fatty Liver Disease (NAFLD) and Nonalcoholic Steatohepatitis (NASH)
NAFLD is the most common liver disease, where fat is accumulated in hepatocytes. High fat diet and uncontrolled diabetes mellitus are the most common causes. As the disease progresses, inflammatory reaction occurs, which is then termed as NASH.

6. Fatty liver progresses to cirrhosis
   i. Fat molecules infiltrate the cytoplasm of the cell (fatty infiltration). These are seen as fat droplets, which are merged together so that most of the cytoplasm becomes laden with fat.

   ii. The nucleus is pushed to a side of the cell, nucleus disintegrates (karyorrhexis), and ultimately the hepatic cell is lysed.

   iii. As a healing process, fibrous tissue is laid down, causing fibrosis of liver, otherwise known as cirrhosis. Liver function tests (see Chapter 26) show abnormal values when chronic liver damage occurs.
Lipotropic Factors
They are required for the normal mobilisation of fat from liver. Therefore, deficiency of these factors may result in fatty liver. They can afford protection against the development of fatty liver.

1. **Choline.** Feeding of choline has been able to reverse fatty changes in animals.

2. **Lecithin and methionine.** They help in synthesis of apoprotein and choline formation. The deficiency of methyl groups for carnitine synthesis may also hinder fatty acid oxidation.

3. **Vitamin E and selenium** give protection due to their anti-oxidant effect.

4. **Omega 3 fatty acids** present in marine oils have a protective effect against fatty liver.

**METABOLISM OF KETONE BODIES**
Carbohydrates are essential for the metabolism of fat or fat is burned under the fire of carbohydrates. The acetyl CoA formed from fatty acids can enter and get oxidized in TCA cycle only when carbohydrates are available.

During starvation and diabetes mellitus, the acetyl CoA takes the alternate fate of formation of ketone bodies.

**A. Ketogenesis**
Acetoacetate is the primary ketone body while beta-hydroxy butyrate and acetone are secondary ketone bodies. They are synthesised exclusively by the liver mitochondria. The steps involved are shown in Figure 11.20.

**Step 1. Condensation**
Two molecules of acetyl CoA are condensed to form acetoacetyl CoA.

**Step 2. Production of HMG CoA**
One more acetyl CoA is added to acetoacetyl CoA to form HMG CoA (beta hydroxy beta methyl glutaryl CoA). The enzyme is HMG CoA synthase. Mitochondrial HMG CoA is used for ketogenesis, while cytosolic fraction is used for cholesterol synthesis.

**Step 3. Lysis**
Then HMG CoA is lysed to form acetoacetate. Acetoacetate may also be formed by the degradation of carbon skeleton of ketogenic amino acids like leucine, lysine, phenylalanine and tyrosine. HMG CoA lyase is present only in liver.

**Step 4. Reduction**
Beta-hydroxy butyrate is formed by reduction of acetoacetate. Ratio between acetoacetate and beta hydroxy butyrate is decided by the cellular NAD:NADH ratio.

**Step 5. Spontaneous decarboxylation**
Acetone is formed (see Fig. 11.20).

**B. Ketolysis**
The ketone bodies are formed in the liver; but they are utilised by extrahepatic tissues. The heart muscle and renal cortex prefer the ketone bodies to glucose as fuel. Tissues like skeletal muscle and brain can also utilise the ketone bodies as alternate sources of energy, if glucose is not available.

Acetoacetate is activated to acetoacetyl CoA by thiophorase enzyme.

\[
\text{Acetoacetate} + \text{Succinyl CoA} \rightarrow \text{Acetoacetyl CoA} + \text{Succinate}
\]
Then acetoacetyl CoA enters the beta oxidation pathway to produce energy. Summary of ketone body metabolism is shown in Figure 11.21.

KETOSIS
i. Normally the rate of synthesis of ketone bodies by the liver is such that they can be easily metabolised by the extrahepatic tissues. Hence the blood level of ketone bodies is less than 1 mg/dl and only traces are excreted in urine (not detectable by usual tests).

ii. But when the rate of synthesis exceeds the ability of extrahepatic tissues to utilise them, there will be accumulation of ketone bodies in blood.

iii. This leads to ketonemia, excretion in urine (ketonuria) and smell of acetone in breath. All these three together constitute the condition known as ketosis.

Causes for Ketosis
1. Diabetes Mellitus: Uncontrolled diabetes mellitus is the most common cause for ketosis. Even though glucose is in plenty, the deficiency of insulin causes accelerated lipolysis and more fatty acids are released into circulation. Oxidation of these fatty acids increases the acetyl CoA pool. Enhanced gluconeogenesis restricts the oxidation of acetyl CoA by TCA cycle, since availability of oxaloacetate is less.

2. Starvation: In starvation, the dietary supply of glucose is decreased. Available oxaloacetate is channelled to gluconeogenesis. The increased rate of lipolysis is to provide alternate source of fuel. The excess acetyl CoA is converted to ketone bodies. The high glucagon level favors ketogenesis. The brain derives 60-75% of energy from ketone bodies under conditions of prolonged starvation. Hyperemesis (vomiting) in early pregnancy may also lead to starvation-like condition and may lead to ketosis.

Explanation for Ketogenesis
i. During starvation and diabetes mellitus, the blood level of glucagon is increased. Glucagon (see Chapter 24) inhibits glycolysis, activates gluconeogenesis, activates lipolysis, decreases malonyl CoA level and stimulates ketogenesis. High glucagon–insulin ratio is potentially ketogenic.

ii. Insulin (see Chapter 24) has the opposite effect; it favors glycolysis, inhibits gluconeogenesis, depresses lipolysis, increases malonyl CoA level and decreases ketogenesis. The ketone body formation is regulated at the following 3 levels:

Level 1: Lipolysis
Free fatty acids are the precursors of ketone bodies. So factors regulating the mobilisation of fatty acid from adipose tissue will also control ketogenesis (Fig. 11.22). Insulin inhibits lipolysis, while glucagon favors lipolysis.

Level 2: Entry of Fatty Acid to Mitochondria
The mobilised fatty acid then enters mitochondria for beta oxidation. Carnitine acyl transferase I (CAT-I) regulates this entry (Fig. 11.8). Malonyl CoA is the major regulator of CAT-I activity. In diabetes and starvation, glucagon is increased, which decreases malonyl CoA and so beta oxidation is stimulated (Fig. 11.22).

Level 3: Oxidation of Acetyl CoA
i. When the above two steps are increased, more acetyl CoA is produced. Normally, acetyl CoA is completely oxidised in the citric acid cycle. In diabetes and starvation, glucagon insulin ratio is increased, and key gluconeogenic enzymes are activated.

ii. When oxaloacetate is diverted for gluconeogenesis; citric acid cycle cannot function optimally. Thus, on the one hand, acetyl CoA...
is generated in excess, on the other hand, its utilization is reduced. This excess acetyl CoA is channelled into ketogenic pathway (see Fig. 24.9 also).

iii. In both diabetes mellitus and starvation, the oxaloacetate is channelled to gluconeogenesis; so the availability of oxaloacetate is decreased. Hence acetyl CoA cannot be fully oxidised in the TCA cycle.

Salient Features of Ketosis
1. Metabolic acidosis. Acetoacetate and beta-hydroxy butyrate are acids. When they accumulate, metabolic acidosis results (see Chapter 29).
2. Reduced buffers. The plasma bicarbonate is used up for buffering of these acids.
3. Kussmaul’s respiration. Patients will have typical acidic breathing (Chapter 24) due to compensatory hyperventilation.
4. Smell of acetone in patient's breath.
5. Osmotic diuresis induced by ketonuria may lead to dehydration.
6. Sodium loss. The ketone bodies are excreted in urine as their sodium salt, leading to loss of cations from the body.
7. Dehydration. The sodium loss further aggravates the dehydration.

Diagnosis of Ketosis
The presence of ketosis can be established by the detection of ketone bodies in urine by Rothera's test. Supportive evidence may be derived from estimation of serum electrolytes, acid-base parameters, glucose and urea estimation.

Rothera’s test: Saturate 5 ml of urine with solid ammonium sulfate. Add 3 drops of freshly prepared sodium nitroprusside followed by 2 ml of liquor ammonia along the sides of the test tube. Development of a purple ring at the junction of the two liquids indicates the presence of acetone or acetoacetic acid in urine. It is not answered by beta hydroxy butyrate. Strip tests based on the same principle are also available.

Gerhardt’s test for acetoacetic acid: To 5 ml of urine, add dilute ferric chloride solution drop by drop, till a maximum precipitate of ferric phosphate is obtained. This is to eliminate the phosphates which may obscure the color in the test. Filter. To the filtrate add excess ferric chloride. A red color indicates the presence of acetoacetic acid. This is not a sensitive test. Salicylates will give a false positive test. (There is no specific test for beta hydroxy butyric acid).

Differential Diagnosis of Ketosis
The urine of a patient with diabetic keto acidosis will give positive Benedict's test as well as Rothera's test. But in starvation ketosis, Benedict's test is negative, but Rothera's test will be positive.

Management of Ketoacidosis
i. Treatment is to give insulin and glucose. When glucose and insulin are given intravenously, potassium is trapped within the cells, and fatal hypokalemia can occur. Hence the clinician should always monitor the electrolytes.
ii. Administration of bicarbonate, and maintenance of electrolyte and fluid balance are very important aspects. See Chapter 24 also.
The word cholesterol is derived from Greek words, chole = bile; steros = solid; ol = alcohol. Almost all nucleated cells (including arterial walls) can synthesise cholesterol. It is widely distributed in the body. In a 70 kg man, a total of about 140 g of cholesterol is available; which is roughly distributed as 30 g in brain and nerves, 30 g in muscles, 30 g in adipose tissue, 20 g in skin, 10 g in blood, 10 g in liver and spleen, 5 g in bone marrow, 3 g in alimentary tract, and 2 g in adrenal gland. Cholesterol is a light yellow crystalline solid. When the crystals are examined under the microscope, they show a notched appearance. Cholesterol is soluble in chloroform and other fat solvents. It is the most important animal steroid from which other steroid compounds are formed. Cholesterol is widely distributed in animal tissues. It is absent in prokaryotes. In plants, cholesterol is absent, but other plant sterols are present. In bacteria and plants, compounds similar to steroids exist, known as hopanoids. Cholesterol was isolated from bile stones by Poulletier de la Salle in 1758. Chevreul ME characterized cholesterol in 1818. Complete structure of cholesterol was enunciated by Heinrich Wieland in 1918, who got Nobel prize in 1927.

Clinical Significance of Cholesterol
The level of cholesterol in blood is related to the development of atherosclerosis and myocardial infarction. Abnormality of cholesterol metabolism characterized cholesterol in 1818. Complete structure of cholesterol was enunciated by Heinrich Wieland in 1918, who got Nobel prize in 1927.

Clinical Significance of Cholesterol
The level of cholesterol in blood is related to the development of atherosclerosis and myocardial infarction. Abnormality of cholesterol metabolism

Box 12.1. Functions of Cholesterol

1. **Cell membranes**: Cholesterol is a component of membranes and has a modulating effect on the fluid state of the membrane.
2. **Nerve conduction**: Cholesterol has an insulating effect on nerve fibers.
3. **Bile acids and bile salts** are derived from cholesterol. Bile salts are important for fat absorption.
4. **Steroid hormones**: Glucocorticoids, androgens and estrogens are from cholesterol.
5. **Vitamin D₃** is from 7-dehydro-cholesterol.
6. **Esterification**: The OH group of cholesterol is esterified to fatty acids to form cholesterol esters. This esterification occurs in the body by transfer of a PUFA moiety by lecithin cholesterol acyl transferase.
may lead to cardiovascular accidents and heart attacks. These are explained in detail in Chapter 25. Functions of cholesterol in the body are enumerated in Box 12.1.

**Structure of Cholesterol**

1. See Fig. 12.1. All steroids have cyclopentano perhydro phenanthrene ring system. It is a fused ring system made up of 3 cyclohexane rings designated as A, B and C and a cyclopentane ring D. The six-membered rings are in a phenanthrene arrangement.

2. Total 27 carbon atoms.

3. One hydroxyl group at third position which is characteristic of all sterols. The OH group is beta-oriented, projecting above the plane of ring.

5. An eight carbon side chain, beta-oriented, attached to 17th carbon.

There are several centers of asymmetry and therefore the possible numbers of isomers are many. One such isomer is produced when the double bond between carbon atoms 5 and 6 of cholesterol is reduced, 2 possible isomers may be formed, e.g., cholestanol (where the hydrogen atom is alpha-oriented, projecting below the plane of the ring) or coprostanol, where the hydrogen atom is beta oriented, projecting above the plane of the ring. Alpha-oriented groups are denoted by a dotted line, whereas the beta-oriented groups are denoted by a solid line. These saturated isomers are formed from cholesterol in the intestine by bacterial reduction.

**Absorption of Cholesterol**

Cholesterol ester present in the diet is hydrolysed by cholesterol-esterase. The free cholesterol is incorporated into bile salt micelle and absorbed into the mucosal cell. Absorption needs micellar formation. There is a specific protein which facilitates the transport of cholesterol into the mucosal cell from the micelle. Inside the mucosal cell, cholesterol is re-esterified and incorporated into chylomicrons. The chylomicrons reach the bloodstream through lymphatics (lacteals) (Chapter 11). This dietary cholesterol reaches the liver through chylomicron remnants. Plant sterols (sitosterol) decrease absorption of cholesterol.

A protein designated NPC1L1 (Niemann Pick C1 Like1) is involved in the absorption of cholesterol. The therapeutic effect of the drug Ezetimibe is by interfering with the function of the protein. ABC (ATP binding cassette proteins) transporter proteins, ABCG5 (Sterolin 1) and ABCG8 (Sterolin 2) constitute a dimeric unit, limiting cholesterol absorption. They promote the secretion of absorbed sterols from intestinal epithelium back into the lumen and thus regulate the amount of cholesterol incorporated into chylomicrons.

**BIOSYNTHESIS OF CHOLESTEROL**

All carbon atoms of cholesterol are derived from acetyl CoA (Konrad Bloch, 1940, Nobel prize in 1964). The biosynthetic pathway was described by Sir John Cornforth and Vladimir Prelog; both of them got Nobel prizes in 1975. The major sites of synthesis of cholesterol are liver, adrenal cortex, testes, ovaries and intestine. All nucleated cells can synthesise cholesterol, including arterial walls. The enzymes involved in the synthesis of cholesterol are partly located in the endoplasmic reticulum and partly in the cytoplasm.

**Step 1: Condensation**

The acetyl CoA is provided by the ATP-citrate lyase reaction as in the case of fatty acid synthesis. Two molecules of acetyl CoA condense to form acetoacetyl CoA catalysed by cytoplasmic aceto-acetyl CoA synthase (Chapter 11, fatty acid synthesis).

**Step 2: Production of HMG CoA**

A third molecule of acetyl CoA condenses with acetoacetyl CoA to form beta-hydroxy beta-methyl glutaryl CoA (HMG CoA). The enzyme is HMG CoA synthase (Chapter 11, Ketogenesis). HMG CoA is present in both cytosol and mitochondria of liver. The mitochondrial pool is used for ketogenesis whereas the cytosolic fraction is utilized for cholesterol synthesis.
Step 3: The Committed Step
The reduction of HMG CoA to mevalonate is catalysed by HMG CoA reductase. It is a microsomal (endoplasmic reticulum) enzyme. It uses 2 molecules of NADPH (Fig. 12.2). Steps 1 and 2 are shared with ketogenic pathway; but step 3 is the first reaction that is unique to the cholesterol biosynthetic pathway. It is the rate-limiting step.

Step 4: Production of 5 Carbon Unit
i. Mevalonate is successively phosphorylated to phospho-mevalonate, to pyrophospho-mevalonate, then to 3-phospho-5-pyrophospho-mevalonate.

ii. This then undergoes decarboxylation to give isopentenyl pyrophosphate, a 5 carbon unit (Fig. 12.3). Step 4 requires 3 molecules of ATP (Fig. 12.4; steps 4-A, 4-B, 4-C and 4-D). One molecule of CO₂ is eliminated. Steps 1, 2, 3 and 4 together may be considered as the first phase of the cholesterol synthesis.

Step 5: Condensation of 5-Carbon Units
Details of the reactions are shown in Figure 12.4, steps 5-A, 5-B, 5-C and 5-D. Thus, 6 numbers of 5-carbon units are condensed to form a 30 carbon compound, Squalene. In summary

\[ 5C + 5C \rightarrow 10C; \ 10C + 5C \rightarrow 15C; \ 15C + 15C \rightarrow 30C \]
**Step 6: Cyclization**

6-A. Squalene now undergoes oxidation by epoxidase, using molecular oxygen and NADPH to form squalene epoxide.

6-B. A cyclase converts it to 30C lanosterol (Fig. 12.5). It is the first steroid compound synthesised.

**Step 7: Cutting to size**

7-A. Next, the 3 additional methyl groups on carbon atoms 4 and 14 are removed to produce zymosterol.

7-B. Then the double bond migrates from 8-9 position to 5-6 position, when desmosterol is formed. Desmosterol is present in fetal brain. It is absent in adult brain and reappears in gliomas (brain tumor).

7-C. Finally, the double bond in the side chain (between carbon 24-25) is reduced by NADPH when cholesterol is formed (Fig. 12.5). A summary of the whole pathway of cholesterol synthesis is given in Figure 12.4.

**Regulation of Cholesterol Synthesis**

1. **Regulation at transcription:** The regulatory enzyme is HMG CoA reductase. Long-term regulation involves regulation of transcription of the gene for HMG CoA reductase. When sufficient cholesterol is present in the cell, transcription of the gene for HMG CoA reductase is suppressed, and cellular synthesis of cholesterol is decreased. When cholesterol in diet is low, synthesis is increased (Fig. 12.6A).

2. Cholesterol regulates the expression of HMG CoA reductase gene and LDLR (LDL receptor) gene. A specific recognition sequence known as the sterol regulatory element (SRE) is present in DNA. SRE binding by sterol regulatory element binding protein (SREBP) is essential for the transcription of these genes. When cholesterol levels are sufficiently high, the SREBP remains as an inactive precursor. The SREBP cleavage activator protein (SCAP), an intracellular cholesterol sensor. When cholesterol is less, SCAP escorts SREBP to Golgi bodies. Two Golgi proteases (S1P and S2P) sequentially cleave the SREBP to a protein which binds to SRE and activates transcription of HMG CoA reductase gene.

3. **Covalent modification:** Short-term regulation is by covalent modification of the enzyme. Cyclic AMP mediated cascade phosphorylates the enzyme which is inactive. Dephosphorylated form is active. Further, the activity of HMG CoA reductase is also regulated by the rate of degradation of enzyme protein (Fig. 12.6B).

4. **Insulin** and thyroxine increase the activity of HMG CoA reductase (Fig. 12.6A).

5. **Cortisol** and glucagon decrease its activity.

6. **Drugs:** Lovastatin and other "statin" group of drugs are competitive inhibitors of HMG CoA reductase. So, they are used in clinical practice to reduce cholesterol level in blood.

**Cholesterol Pool and Cholesterol Metabolism**

The total body cholesterol content varies from 130-150 grams. LDL (low density lipoprotein) transports cholesterol from the liver to the peripheral tissues and HDL (high density lipoprotein) transports cholesterol from tissues to liver. Cells of extrahepatic tissues take up cholesterol from LDL. The free cholesterol released within the cell has the following fates:

1. Incorporated into cell membranes.
2. Metabolised to steroid hormones, especially in adrenal cortex and gonads.
3. Esterified with saturated fatty acids and stored in the cell. The enzyme ACAT (acyl cholesterol acyl transferase) helps in this reaction.
4. Esterified with poly-unsaturated fatty acids (PUFA) by the action of LCAT (lecithin cholesterol acyl transferase) and incorporated into HDL, transported and finally excreted through liver.

**Excretion of Cholesterol**

Average diet contains about 300 mg of cholesterol per day. Body synthesizes about 700 mg of cholesterol per day. Out of this total 1000 mg, about 500 mg of cholesterol is excreted through bile. This cholesterol is partly reabsorbed from intestines. Vegetables contain plant sterols which inhibit the re-absorption of cholesterol. The unabsorbed portion is acted upon by intestinal bacteria to form cholestanol and coprostanol. These are excreted (fecal sterols). Another 500 mg of cholesterol is converted to bile acids, which are excreted in the bile as bile salts.

**Liver and Cholesterol**

The liver has a major role in controlling the plasma levels of LDL cholesterol.

1. Liver synthesises cholesterol
2. Liver removes cholesterol from Lp remnants.
3. Liver is the only organ that can excrete cholesterol through bile.
4. Liver converts cholesterol to bile acids.

**PLASMA LIPIDS**

Total plasma lipid is 400-600 mg/dl. Normal values of lipid fractions are shown in Table 12.2. Out of this, 40% is cholesterol; 30% is phospholipids; 20% is triglycerides. Since lipids are insoluble in water, they need the help of carriers in plasma. Therefore, they are complexed with proteins to form lipoproteins. The protein part of lipoprotein is called apolipoprotein. The lipoproteins are usually abbreviated as Lp.

**Classification of Lipoproteins**

Depending on the density (by ultra centrifugation) or on the electrophoretic mobility, the lipoproteins in plasma are classified into five major types (see Figs 12.7 and 12.8).

1. **Chylomicrons.** Contains apoprotein B-48.
2. **Very low density lipoproteins** (VLDL) or pre-beta lipoproteins. Main apoprotein is B-100.
3. Intermediate density lipoproteins (IDL) or broad-beta lipoproteins

4. Low density lipoproteins (LDL) or beta-lipoproteins. Major apoprotein in LDL is B-100.

5. High density lipoproteins (HDL) or alpha-lipoproteins. Major apoprotein in HDL is apo-A.

Free fatty acids (FFA) or nonesterified fatty acids (NEFA) are complexed with albumin. FFAs are not generally included in the classification of lipoproteins, because they are loosely bound to the protein.

### General Characteristics of Lipoproteins

Their salient characteristics and compositions are given in Table 12.3. The lipoprotein molecules have

</table>
a polar periphery made of proteins, polar heads of phospholipids and cholesterol. The inner core consists of the hydrophobic TAGs and tails of phospholipids. The apoproteins also increase the solubility of lipids.

**Separation by Ultracentrifugation**
The lipoproteins are characterised on the basis of their density. Fat is less dense than water; so fat floats on water. Lipoproteins with high lipid content will have a low density and so float on centrifugation. Those with high protein content will sediment easily and have a high density. Depending on the floatation constant (Sf), different fractions can be separated (Table 12.3 and Fig. 12.7).

**Separation by Electrophoresis**
The basic principle of electrophoresis is given in chapter 54. The serum is applied on cellulose acetate, electric current is applied for 2 hours, the strip is dried and stained with lipid dyes, such as **Oil Red O**. As a general rule, those with higher protein content will move faster towards the anode and those with fewer proteins have minimum mobility (see Fig. 12.7).

**Apo-lipoproteins**
The protein part of lipoprotein is called apolipoprotein (apo-Lp) or apoprotein. For details of apoproteins, see Table 12.4. All apoproteins are mainly synthesised in liver; but small quantities are produced from almost all organs. Intestinal cells produce small quantities of apo-A. Apart from solubilising the lipid part, the protein components have specific functions.

**Apo-A-I.** It activates lecithin-cholesterol acyl transferase (LCAT). It is the ligand for HDL receptor. It is anti-atherogenic.

**Apo-B-100.** It is a component of LDL; it binds to LDL receptor on tissues (Fig. 12.10). Apo-B-100 is one of the biggest proteins, having 4536 amino acids, with a molecular weight of 550 kDa. It is synthesised in liver.

**Apo-B-48.** It is synthesized in intestinal cells. It is the structural component of chylomicrons.
Apo-B-100 and apo-B-48 are products of the same gene, but in the intestine, the mRNA undergoes editing, so as to produce the B-48 protein (Fig. 12.11). B-48 is so named because it is only 48% of the size of B-100.

4. Apo-C-II. It activates lipoprotein lipase.

5. Apo-E. It is an arginine-rich protein. It is present in chylomicrons, LDL and VLDL. Astrocytes also make apo-E; it is involved in cellular transport of lipids in CNS. Apo-E has I, II, III and IV isoforms, due to independent alleles in the genes. Apo E-IV isoform is implicated in the development of senile dementia and Alzheimer's disease. Apo-E is also associated with lipoprotein glomerulopathy.

1. CHYLOMICRONS

Synthesis of chylomicrons

Chylomicrons are formed in the intestinal mucosal cells, and secreted into the lacteals of lymphatic system (Chapter 11). They are rich in triglyceride (Fig. 12.9). If lipemic serum is kept overnight in the refrigerator, chylomicrons rise as a creamy layer to the top, leaving the subnatant clear. When the chylomicrons are synthesised by the intestinal mucosa, they contain only apo-B-48 and apo-A but apo-C and apo-E are added from HDL in blood during transport (Fig. 12.10).

Metabolism of Chylomicrons

i. Main sites of metabolism of chylomicrons are adipose tissue and skeletal muscle. The half-life of chylomicrons in blood is about 1 hour.

ii. The enzyme lipoprotein lipase (LpL) is located at the endothelial layer of capillaries of adipose tissue, muscles and heart; but not in liver. Apo C-II present in the chylomicrons activates the LpL (Table 12.4). The LpL hydrolyses triglycerides present in chylomicrons into fatty acids and glycerol. Muscle or adipose tissue cells take up the liberated fatty acids (Fig. 12.10).

iii. Following injection of heparin, the LpL is released from the tissues and lipemia is thus cleared. This is called post-heparin lipolytic activity. Lack of C-II leads to decreased activity of LpL and consequent accumulation of chylomicrons and VLDL in blood. Insulin increases LpL activity.

Liver Takes up Chylomicron Remnants

As the TAG content is progressively decreased, the chylomicrons shrink in size. These remnants containing apo-B-48 and apo-E are taken up by hepatic cells by receptor mediated endocytosis.

Apo-E binds the hepatic receptors (Fig. 12.10).

Function of Chylomicrons

Chylomicrons are the transport form of dietary triglycerides from intestines to the adipose tissue for storage; and to muscle or heart for their energy needs.

2. VERY LOW DENSITY LIPOPROTEINS

Synthesis of VLDL

They are synthesised in the liver from glycerol and fatty acids and incorporated into VLDL along with hepatic cholesterol, apo-B-100, C-II and E. Apo-B-100 is the major lipoprotein present in VLDL when it is secreted. Apo-E and C-II are obtained from HDL in plasma.

Metabolism of VLDL

The half-life of VLDL in serum is only 1 to 3 hours. When they reach the peripheral tissues, apo-C-II activates LpL which liberates fatty acids that are taken up by adipose tissue and muscle. The remnant is now designated as IDL (intermediate density lipoprotein) and contains less of TAG and more of cholesterol (Table 12.3 and Fig. 12.18). The major fraction of IDL further loses triglyceride, so as to be converted to LDL (low density lipoprotein). This conversion of VLDL to IDL and then to LDL is referred to as lipoprotein cascade pathway (Fig. 12.18). A fraction of IDL is taken up by the hepatic receptors.

Function of VLDL

VLDL carries triglycerides (endogenous triglycerides) from liver to peripheral tissues for energy needs.

3. LOW DENSITY LIPOPROTEINS (LDL)

LDL transports cholesterol from liver to peripheral tissues. The only apoprotein present in LDL is apo B100 (Fig. 12.12). Most of the LDL particles are derived from VLDL, but a small part is directly released from liver. The half-life of LDL in blood is about 2 days.

Metabolism of LDL and LDL Receptors

LDL is taken up by peripheral tissues by receptor mediated endocytosis (see Fig. 12.13). LDL receptors are present on all cells but most abundant in hepatic cells. LDL receptors are located in specialised regions called clathrin-coated pits.
Fig. 12.13. Uptake and fate of LDL

Function of LDL
About 75% of the plasma cholesterol is incorporated into the LDL particles. LDL transports cholesterol from liver to the peripheral tissues. The cholesterol thus liberated in the cell has three major fates:

i. It is used for the synthesis of other steroids like steroid hormones.

ii. Cholesterol may be incorporated into the membranes.

iii. Cholesterol may be esterified to a MUFA by acyl cholesterol acyl transferase (ACAT) for storage. The cellular content of cholesterol regulates further endogenous synthesis of cholesterol by regulating HMG CoA reductase.

LDL and Clinical Applications
LDL concentration in blood has positive correlation with incidence of cardiovascular diseases. A fraction of cholesterol is taken up by macrophages, this is not a regulated pathway. Increased levels of LDL or modification of LDL by glycation (as seen in diabetes mellitus) or oxidation increases the fraction of cholesterol taken up by macrophages. LDL infiltrates through arterial walls, and is taken up by macrophages or scavenger cells. This is the starting event of atherosclerosis leading to myocardial infarction (see coronary artery diseases in Chapter 25). When these cells become engorged with cholesterol, foam cells are formed, that get deposited in the subendothelial space triggering formation of atheromatous plaque (see Fig. 25.3). Procoagulant changes are induced in the endothelium resulting in increased chances of thrombosis and coronary artery disease (Fig. 25.4).

Since LDL-cholesterol is thus deposited in tissues, the LDL (low density lipoprotein) variety is called “bad cholesterol” and LDL as “Lethally Dangerous Lipoprotein” in common parlance (Fig. 12.14 and Box 12.2).

Lipoprotein (a)

i. Lipoprotein (a) should not be confused with apo-A (see Box 12.3). Lp(a) is very strongly associated with myocardial infarction and is sometimes called the “little rascal”.

Box 12.2. LDL Cholesterol is "Bad"

LDL, especially oxidized and glycated LDL, creates a pro-coagulant surface on the endothelium, causing blood clot formation. Oxidized LDL is found in higher levels in cigarette smokers, patients with diabetes mellitus and in insulin resistance.
ii. Lp(a), when present, is attached to apo-B-100 by a disulfide bond.

iii. In 40% population, there is no detectable level of Lp(a) in serum. In 20% of population, the Lp(a) concentration in blood is more than 30 mg/dl; and these persons are susceptible for heart attack at a younger age.

iv. Lp(a) is associated with heart attacks at the age of 30 or 40 years. Indians have a higher level of Lp(a) than Western populations.

v. Lp(a) has significant homology with plasminogen. So it interferes with plasminogen activation and impairs fibrinolysis (Fig. 12.15). This leads to unopposed intravascular thrombosis and possible myocardial infarction.

4. HIGH DENSITY LIPOPROTEIN (HDL)

High density lipoproteins transport cholesterol from peripheral tissues to the liver. The major apoproteins in HDL are Apo-A1, with some Apo-A2, Apo-C and Apo-E. HDL serves as a plasma reservoir of Apo-C and Apo-E which can be transferred to VLDL and chylomicrons and back.

Box 12.3. Lp(a) and Apo-A are different

Apo-A is a constituent of HDL. This "A" is always written in capital letters. It is seen in all persons. It is anti-atherogenic.

Lp(a) is seen in high levels only in some persons. When present, it is associated with LDL. This "a" is always written in small letters. It is highly atherogenic and correlated with heart attacks in younger age group.

Fig. 12.14. Forward and reverse transport of cholesterol

Fig. 12.15. Lp(a) competitively inhibits plasminogen activation; and so inhibits fibrinolysis

Metabolism of HDL

i. The intestinal cells synthesise components of HDL and release into blood. The nascent HDL in plasma is discoid in shape (Fig. 12.16).

ii. The free cholesterol derived from peripheral tissue cells are taken up by the HDL. The apo-A-I of HDL activates LCAT (lecithin cholesterol acyl transferase) present in the plasma. The LCAT then binds to the HDL disk. The reaction is shown in Fig. 12.17. The cholesterol from the cell is transferred to HDL by a cholesterol efflux regulator protein which is an ABC protein.

iii. Lecithin is a component of phospholipid bilayer of the HDL disk. Structure of lecithin is shown in Chapter 7. The second carbon of lecithin contains one molecule of polyunsaturated fatty acid (PUFA). It is transferred to the third hydroxyl group of cholesterol to form cholesterol ester. The esterified cholesterol which is more hydrophobic, moves into the interior of the HDL disk.

iv. This reaction continues; till HDL becomes spherical with a lot of cholesterol esters are formed. This HDL particle designated as HDL-3.

v. Mature HDL spheres are taken up by liver cells by apo-A-I mediated receptor mechanism (see Figs 12.16 and 12.18.). HDL is taken up by hepatic scavenger receptor B1. Hepatic lipase hydrolyses HDL phospholipid and TAG, and cholesterol esters are released into liver.
cells. The cholesterol that reaches the liver is used for synthesis of bile acids or excreted as such in bile.

The scavenger receptor B1 (SR-B1) is identified as an HDL receptor with dual role in HDL metabolism. In liver and steroidogenic tissues, it delivers cholesteryl ester to tissues whereas in the tissues it is involved in reverse cholesterol transfer.

vi. When the HDL-3 remains in circulation, the cholesteryl ester from HDL is transferred to VLDL, IDL and LDL by a Cholesterol Ester Transfer Protein (CETP). This will help to relieve product inhibition of LCAT so that more cholesterol can be taken up. Triacyl glycerol from VLDL, IDL and LDL is transferred to HDL in exchange for the cholesterol ester. The HDL particles that are rich in triacyl glycerol and spherical are called HDL-2. These particles are first acted upon by hepatic triglyceride lipase (HTGL) before being taken up by scavenger B1 receptors in liver.

vii. The efflux of cholesterol from peripheral cells to HDL is mediated by the ABC transporter protein. The reverse cholesterol transport to liver through HDL needs the activity of LCAT, CETP and Apo-D.

**Functions of HDL**

i. HDL is the main transport form of cholesterol from peripheral tissue to liver, which is later excreted through bile (Table 12.3). This is called reverse cholesterol transport by HDL.

ii. The only excretory route of cholesterol from the body is the bile.

---

**Fig. 12.16. HDL metabolism**

---

**Fig. 12.17. Lecithin cholesterol acyl transferase (LCAT)**

---

**Fig. 12.18. Summary of lipoprotein metabolism**
iii. Excretion of cholesterol needs prior esterification with PUFA. Thus PUFA will help in lowering of cholesterol in the body, and so PUFA is anti-atherogenic.

Clinical Significance of HDL
The level of HDL in serum is inversely related to the incidence of myocardial infarction. As it is “anti-atherogenic” or “protective” in nature, HDL is known as “good cholesterol” in common parlance (Fig. 12.14). It is convenient to remember that "H" in HDL stands for "Healthy". HDL level below 35 mg/dl increases the risk, while level above 60 mg/dl protects the person from coronary artery diseases. A summary of the lipoprotein metabolism is shown in Figure 12.18.

HDL Specific Receptors
The main receptor for taking up HDL is the Scavenger Receptor B1 (SR-B1). In liver, this receptor binds the HDL with the help of apo-A-1. Then cholesterol is internalised, but the HDL particle and apo-A-1 are not taken up. In the tissues, the SR-B1 accepts the cholesterol into the HDL. Thus SR-B1 has a dual role in HDL metabolism.

HDL related transport proteins
The reverse transport of cholesterol from tissues to liver needs two transporters; ABC-A1 (ATP binding cassette transporter A1) and ABC-G1. The ABC-G1 is helping the transport of cholesterol from cells to HDL. ABC-A1 helps efflux of cholesterol into apo-A1 in the discoid HDL.

HDL subfractions
HDL-1 or HDLC (density 1.063 g/ml) is seen in animals fed with cholesterol. It contains apo-E.

HDL-2 (density 1.063-1.125 g/ml) HDL-2 is definitely "good" and its level is inversely proportional to atherosclerosis. It is again subfractionated into HDL-2a and 2b. HDL-2b is the main anti-atherogenic factor. Apo A-I is maximally present in HDL-2b.

HDL-3 (density 1.125-1.21 g/ml) is further fractionated into 3a, 3b and 3c. HDL-3 contains apo-A-II. HDL-3 also contains apo-D (lipid transfer protein).

HDL cycle: By the action of LCAT, more cholesterol is trapped into the nascent discoid HDL. As more and more cholesterol is accepted, the particle size is increased, HDL-3 is generated. As further cholesterol is taken up, particle size is further increased, and less dense HDL-2 is formed. This interchange of HDL-2 and HDL-3 is called the HDL cycle.

Apolipoprotein J (apo J) is a glycoprotein associated with HDL-2. It is synthesised by foam cells in atheromatous plaques. Apo-J can inhibit macrophage mediated cell damage. It is cytotoxic and anti-atherogenic.

LpX is a lipoprotein with cathodal migration, seen in patients with obstructive jaundice.

5. FREE FATTY ACID (FFA)
i. It is also known as nonesterified fatty acids (NEFA) (Table 12.3). It is complexed with albumin in plasma.

ii. The FFA is derived from lipolysis of triglyceride stored in adipose tissue by hormone sensitive lipase (Chapter 11). Free fatty acids may be long chain saturated or unsaturated fatty acids.

iii. The FFA molecules are transported to heart, skeletal muscle, liver and other soft tissues. The free fatty acids are either oxidised to supply energy or incorporated into tissue lipids by esterification.

iv. In the tissue cells, FFA-albumin complex is dissociated, FFA binds with a fatty acid transport protein. It is a co-transporter with sodium. After entry into the cell, the FFA is bound to fatty acid binding protein.

v. The half-life of free fatty acids in plasma is very short; only 1-2 minutes. During starvation, about 40-50% energy requirement of the body is met by oxidation of FFA.

vi Blood level of FFA is very low in the fully fed condition, high in the starved state, and very high in uncontrolled diabetes mellitus.

Cholesterol and Beta Cells
The accumulation of cholesterol in beta cells causes perturbations in glucose metabolism, reduces insulin secretion and can be associated with a diabetic phenotype. Cholesterol is also a key determinant of beta cell membrane organization and cell survival. The ATP-binding cassette transporter A1, which effluxes cholesterol to lipid-free/lipid-poor apolipoprotein A-I, the principal apolipoprotein in HDLs, is crucial for maintaining beta-cell cholesterol homeostasis and function. There is also evidence suggesting that different lipoprotein classes have varying effects on beta-cell function and survival. It can cause beta-cell loss if allowed to accumulate in the cells in an unregulated manner. The maintenance of beta-cell cholesterol homeostasis, therefore, is important for preventing the onset of insulin resistance and the development of type 2 diabetes.

Oxidized Metabolites
In contrast to their parent molecule cholesterol, the oxidized metabolites are able to cross the blood-brain barrier. There is a concentration-driven flux of 24-hydroxycholesterol
(24-OHC) from the brain into the circulation, which is of major importance for elimination of excess cholesterol from the brain. The opposite flux of 27-hydroxycholesterol (27-OHC) from the circulation into the brain may regulate a number of key enzymes within the brain. In vitro experiments suggest that the balance between the levels of these two molecules may be of importance for the generation of beta-amyloid peptides. In primary cultures of rat hippocampal cells 27-OHC is able to suppress expression of the activity regulated cytoskeleton-associated protein (Arc), a protein important in memory consolidation which is reduced in patients with Alzheimer’s disease (AD).

FORMATION OF BILE ACIDS

Bile salts were first crystallised by Plattner in 1844. Correct elementary formula of cholic acid (C24H40O5) was reported by Adolf Strecker in 1848, and that of cholesterol (C27H46O) by Reinitzer in 1888. Windaus (Nobel prize, 1928) in 1918 showed the conversion of cholesterol to bile acid. Complete structural analysis was done by Heinrich Wieland in 1918, who got Nobel prize in 1927.

Bile acids are synthesised in the liver from cholesterol. They contain 24 carbon atoms. All of them have an alpha-oriented hydroxyl group at position 7. The reactions for synthesis of bile acids are summarised below:
1. Cholesterol hydroxylated at 3/7/12 positions
2. Removal of 3-carbon unit, to make it 24 C
3. Conjugation with glycine
4. Secretion into intestinal canal
5. In the intestine, deconjugation and removal of hydroxyl groups.

1. Hydroxylation Reactions
The first and rate-limiting step is the introduction of this hydroxyl group by the enzyme 7-alpha-hydroxylase. It is a microsomal enzyme. Then the beta-oriented OH group of C3 is converted to alpha type by an isomerase. A third OH group is added at 12th carbon in the case of cholic acid.

Chenodeoxycholic acid, another primary bile acid has only two hydroxyl groups at positions 3 and 7 (Fig. 12.19). Ring B is reduced in all cases.

2. Removal of 3 Carbon Unit
The side chain is first hydroxylated at 26 C and then oxidised to COOH group. This is followed by cleavage at 24 C, with removal of propionic acid (3 carbon) unit.

3. Formation of Bile Salts
The primary bile acids are now conjugated with either glycine or taurine to form bile acids. They are glyco-cholic acid, tauro cholic acid, glyco chenodeoxycholic acid and tauro chenodeoxycholic acid (Fig. 12.20). The major conjugated bile acid is glycocholic acid. Conjugation adds more polar groups and increases the efficiency of bile acids as surfactants. The conjugated bile acids are excreted through the bile. In the bile they exist as bile salts (sodium or potassium salts of conjugated bile acids).

4. Secondary Bile Acids/Bile Salts
Primary bile acids are acted upon by intestinal bacteria which result in deconjugation. The deconjugated bile acids are then partly converted to secondary bile acids by removal of the alpha hydroxyl group at position 7. Cholic acid is thus converted to deoxycholic acid and chenodeoxycholic acid to lithocholic acid (Fig. 12.20).

Functions of Bile Salts
They facilitate the digestion of lipids. They can form molecular aggregates called micelle which bring about the absorption of lipids. Bile salt micelle also plays an important role in keeping the cholesterol in solution.

During the last two decades, it has been discovered that bile acids are regulatory molecules. Bile acids have been discovered to activate specific nuclear receptors (farnesoid X receptor, pregnane X receptor, and vitamin D receptor), G protein coupled receptor TGR5 (TGR5), and cell signaling pathways (c-jun N-terminal kinase 1/2, AKT, and ERK 1/2) in
cells in the liver and gastrointestinal tract. Activation of nuclear receptors and cell signaling pathways alter the expression of numerous genes encoding enzyme/proteins involved in the regulation of bile acid, glucose, fatty acid, lipoprotein synthesis, metabolism, transport, and energy metabolism. Bile acids appear to function as nutrient signaling molecules primarily during the feed/fast cycle as there is a flux of these molecules returning from the intestines to the liver following a meal. Bile acid-controlled signaling pathways are promising novel drug targets to treat common metabolic diseases, such as obesity, type 2 diabetes, hyperlipidemia, and atherosclerosis.

**Enterohepatic Circulation of Bile Salts**

Of the total bile salts reaching the intestine (15-30 g/day) only a very small fraction, about 300-500 mg/day is excreted through feces. The rest is reabsorbed from ileum, reaches liver and re-excreted through bile. This is referred to as the enterohepatic circulation. When bile acid binding resin (cholestyramine) is given, the re-absorption of bile acids is inhibited. Hence more cholesterol gets converted to bile acids and cholesterol is decreased.

**Bile**

It is the chief secretion of liver, the largest gland in the body. Daily volume of secretion is about 500 ml. The secreted bile is stored in the gallbladder and released on demand. The pH of bile in hepatic duct is 7.8, and in gallbladder is 7.4. An enzyme present in bile is alkaline phosphatase.

**Secretion of bile**

Choleretics are substances which stimulate the secretion of bile by the liver. Cholagogues stimulate the release of bile from the gallbladder. The most important choleretics are bile salts, the hormone secretin and vagal stimulation. Cholecystokinin is the most powerful cholagogue. The release of cholecystokinin itself is stimulated by fatty acids and amino acids in duodenum.

**Functions of Bile**

1. The alkaline pH of the bile serves to neutralise the acidity of the gastric juice.
2. The bile salts are efficient surfactants and detergents.
3. Bile is the only route of excretion for bilirubin, the end product of heme catabolism.
4. It serves to excrete cholesterol, thus regulating the body cholesterol pool.
5. Bile serves as the medium of excretion for several drugs, which are detoxified by the liver.

**Solubilization of Cholesterol in Bile**

The relative concentration of cholesterol in the bile favors the precipitation and resultant stone formation; it is referred to as lithogenic bile. Bile salts and phospholipids in the bile play a significant role in keeping the cholesterol in solution by forming mixed micelle. Infections of the gallbladder may predispose to stone formation. Dehydration may also lead to precipitation of cholesterol crystals.

**Cholesterol and Cardiac Diseases**

The level of cholesterol in blood is related to the development of atherosclerosis. Abnormality of cholesterol metabolism may lead to cardiovascular accidents and heart attacks. Please see Chapter 25 for details.
SCFAs, butyric acid (4C) and caproic acid (6C) are seen in butter and ghee; the name butyric is derived from butter. MCFAs, capric acid (10C), lauric acid (12C) and myristic acid (14C) are present in coconut oil and human milk. Normal skin has a very thin layer of sebum secretion with MCT (medium chain triglyceride) containing lauric acid, which prevents bacterial entry into the body.

Digestion of Medium Chain Fatty Acids

i. Digestion and metabolism of SCFAs and MCFAs are drastically different from those of LCFAs. Short and medium chain fatty acids containing triglycerides (SCT and MCT) do not require prolonged digestion.

ii. Pancreatic lipase and bile salts are not required. MCT-specific lipase catalyses the complete hydrolysis of SCT/MCT into glycerol and short/medium chain fatty acids.

iii. These free MCFAs diffuse directly into portal circulation.

iv. SCFA and MCFA are preferentially oxidized by peripheral cells, and so they are not deposited in adipose tissues. A comparison is given in Table 13.1.

Very Long Chain Fatty Acids (VLCFA)
Fatty acids having 20 or more carbon atoms are called very long chain fatty acids (VLCFA). Eicosa penta-enoic acid (EPA) (C-20, 5 double bonds) and docosa hexa-enoic acid (DHA) (C-22, 6 double bonds) are good examples of VLCFA. DHA is synthesized in liver from linolenic acid (Omega-3, C-18, 3 double bond). DHA is available in large quantities in fish oils. DHA is especially required for the development of brain and retina. Low level of DHA in blood is seen in patients with retinitis pigmentosa.

In human beings, DHA is accumulated in brain before birth and up to 12 weeks after birth. Outer segments of retinal rods contain high concentrations of DHA, which gives high fluidity to the membranes. This is required for the lateral and rotational movement of rhodopsin within the membrane during photo-activation.

Lignoceric acid (C-24, saturated), nervonic acid (C-24, 1 double bond) and cerebrobilin acid (C-24, saturated hydroxy acid) are other VLCFAs seen in substantial quantities in brain, and are components of sphingomyelins.

VLCFAs (20 C and above) are partly oxidised in peroxisomes to smaller (18 C) fatty acids, which then leave peroxisomes to enter mitochondria. This peroxisomal oxidation differs from beta oxidation in that the electrons from FADH2 (step 1 of beta oxidation) are directly donated to oxygen to form hydrogen peroxide. So this step does not produce ATP. Peroxisomal production of hydrogen peroxide is one mechanism to kill bacteria by neutrophils. The unwanted hydrogen peroxide is then detoxified by catalase. Catalase is the marker enzyme for peroxisomes.

Deficient oxidation of VLCFA by peroxisomal enzyme systems leads to adreno-leukodystrophy (Chapter 2), where VLCFA accumulate and myelin sheaths are destroyed. It is an X-linked condition. The child usually dies in the first decade of life.

In Zellweger syndrome, peroxisomes are empty or peroxisomal enzymes are not transported correctly into peroxisomes (Box 41.1). Zellweger syndrome, adrenoleukodystrophy and infantile Refsum’s disease are together classified as Peroxisomal biogenesis disorders.

POLYUNSATURATED FATTY ACIDS (PUFA)
The important polyunsaturated fatty acids are:
1. Linoleic acid (18 C, 2 double bonds)
2. Linolenic acid (18 C, 3 double bonds)
3. Arachidonic acid (20 C, 4 double bonds)
They are present in good quantities in vegetable oils such as sunflower oil (Fig. 7.2, Table 7.4).

They are used to esterify cholesterol, whereby the latter can be excreted. So, PUFA in general are anti-atherogenic (see Chapter 12, under HDL). Functions of PUFA are shown in Box 13.1. Clinical manifestations of PUFA / EFA deficiency are shown in Box 13.2.

Other PUFAs belonging to very long chain fatty acids (VLCFA) are timnodonic acid (20 C, 5 double bonds); clupanodonic acid (22 C, 5 double bonds) and cervonic acid (22 C, 6 double bonds). They are present in fish oils. They are important for development of human brain.
Lipid Peroxidation
In vitro, peroxidation would lead to rancidity of fats and oils. In vivo, the membrane lipids are more liable to attack by free radicals and produce damage to the integrity of the membrane (Chapter 20). In naturally occurring lipids, anti-oxidants prevent the lipid peroxidation. Vitamin E or tocopherol is an important antioxidant in the human body.

Elongation of fatty acids
The Microsomal system (microsomal fatty acid elongase system) elongates saturated or unsaturated fatty acyl CoA by successive addition of two-carbon units. Malonyl CoA is the acetyl donor. NADPH is required for the reaction. This system can elongate fatty acids having 10 carbon units onward up to the length of 22 or 24 carbons. The steps in the elongation are:

a. Acyl CoA (10 C in length) + malonyl CoA to produce 3-keto acyl CoA (12 C). Enzyme is 3-keto acyl CoA synthase. One molecule of carbon dioxide is released in this reaction.
b. 3-keto acyl CoA is reduced to 3-hydroxy acyl CoA. Enzyme is 3-keto acyl CoA reductase. NADPH is needed.
c. One water molecule is removed from 3-hydroxy acyl CoA to make 2-trans enoyl CoA, with the help of 3-hydroxy acyl CoA dehydrase.
d. 2-trans enoyl CoA is reduced to acyl CoA (12 C) with the help of trans enoyl CoA reductase and NADPH. This is repeated till the necessary length is achieved. Finally CoA is removed from the molecule.

Desaturation of Fatty Acids
Monounsaturated fatty acids can be synthesized from saturated fatty acids by a \( \Delta^9 \) desaturase enzyme system present in the endoplasmic reticulum. The reaction utilises NADH and molecular \( O_2 \) and cytochrome b5. Thus, stearic acid is desaturated to form oleic acid.

PUFA may be formed from monounsaturated fatty acids by the introduction of double bonds only between an existing double bond and carboxyl end of the fatty acid (but not between the omega end and an existing double bond). Hence linoleic acid cannot be synthesized from oleic acid. However, linoleic acid can be converted to arachidonic acid by elongation and desaturation (see Fig. 13.1).

Essential Fatty Acids (EFA)
Normal dietary allowance of PUFA is 2-3% of total calories. Linoleic acid (\( \omega_6, 18C, \Delta 9,12 \)) and linolenic acid (\( \omega3, 18C, \Delta 9,12,15 \)) are the only fatty acids which cannot be synthesized in the body. Their structure is shown in figure 7.2. They have to be provided in the food; hence they are essential fatty acids. Arachidonic acid can be formed, if the dietary supply of linoleic acid is sufficient. For deficiency manifestations of EFA, please see Box 13.2. The relation of PUFA with cholesterol is described in Chapter 12.

Gamma-linolenic Acid (GLA)
It is an essential fatty acid of the omega-6 family. In the body, GLA is produced from Linoleic acid.

Box 13.1. Significance of PUFA
1. PUFAs are seen in vegetable oils.
2. They are nutritionally essential; and are called Essential Fatty Acids.
3. Prostaglandins, thromboxanes and leukotrienes are produced from arachidonic acid.
4. PUFAs form integral part of mitochondrial membranes. In deficiency of PUFA, the efficiency of biological oxidation is reduced.
5. They are components of membranes. Arachidonic acid is 10-15% of the fatty acids of membranes.
6. As double bonds are in cis configuration; the PUFA molecule cannot be closely packed. So PUFAs will increase the fluidity of the membrane.
7. As PUFAs are easily liable to undergo peroxidation, the membranes containing PUFAs are more prone for damage by free radicals.
8. The production of DHA (docosa hexa enoic acid) from alpha linolenic acid is limited. DHA is present in high concentrations in fish oils. DHA is present in high concentrations in retina, cerebral cortex and sperms.

Box 13.2. Clinical Significance of PUFA and EFA
1. Persons with normal diet will not have any deficiency; but those who are on parenteral nutrition for long periods will have deficiency.
2. PUFAs are used for esterification and excretion of cholesterol. PUFA will reduce serum cholesterol level (Ch 12)
3. Deficiency of EFA causes acanthocytosis, hyperkeratosis, acrodermatitis and hypercholesterolemia.
4. EFA deficiency is connected with acrodermatitis enteropathica, hepatorenal syndrome and CNS manifestations
5. Elevated PUFA levels are seen in Zellweger's syndrome.
6. DHA levels in blood are low in patients with retinitis pigmentosa.
7. Trans fatty acids will compete with EFAs, and may increase the EFA deficiency and decrease fluidity of membranes.
8. Trans fatty acids decrease HDL-cholesterol and may cause atherosclerosis.
GLA is elongated and desaturated to arachidonic acid (AA). GLA may prevent diseases by dilating blood vessels, lowering blood pressure, and preventing atherosclerosis. GLA inhibits the growth of tumors and the spread of cancer. Dietary sources of GLA are plant-seed oils of primrose and borage. GLA is also found in human milk.

**Saturation and Trans Fatty Acids**

Hydrogenation of vegetable oil produces saturation of the double bonds; the product is called Margarine or Vanaspathy. During the hydrogenation process, some cis double bonds change to trans configuration. Fatty acids with trans double bonds (Trans fatty acids) are injurious to health. They decrease fluidity of membranes; decrease HDL-cholesterol, increase LDL-cholesterol and may cause atherosclerosis.

**EICOSANOIDS**

They are 20 C compounds (Greek, eikosi = twenty), derived from arachidonic acid. Their names are:

1. Prostanoids, containing
   1-a. Prostaglandins (PGs);
   1-b. Prostacyclins (PGIs);
   1-c. Thromboxanes (TXs)
2. Leukotrienes (LTs)

**PROSTAGLANDINS (PGs)**

Prostaglandins were first isolated by Ulf von Euler in 1935 (Nobel prize in 1970). In 1982 Nobel prizes were awarded to Bengt Samuelsson (biosynthesis of PGs) and Sir John Vane (effect of aspirin on PGs). PGs were originally isolated from prostate tissue and hence the name. But they are present in almost all tissues. They are the most potent biologically active substances; as low as one nanogram/ml of PG will cause smooth muscle contraction. The diverse physiological roles of prostaglandins confer on them the status of local hormones.

**Chemical Structure**

All prostaglandins are considered to be derived from the 20 C cyclic saturated fatty acid, prostanoic acid (Fig. 13.2A). The five carbon ring is saturated. All naturally occurring PGs have an alpha-oriented OH group at C15.

**Classification of Prostaglandins**

According to the attachment of different substituent groups to the ring, PGs are named with capital letters such as A, B, E and F (Table 13.2). PGF is designated as alpha to denote the projection of the OH group in naturally occurring prostaglandins.
In the same series, depending on number of double bonds on the side chains they are denoted by a subscript after the capital letter, e.g. PGE₁, PGE₂, PGE₃, etc. (Table 13.2).

1. Series 1 contains 1 double bond at 13–14 (trans)
2. Series 2 have 2 double bonds at 13–14 (trans) and 5–6 (cis). This is the most common variety.
3. Series 3 have 3 double bonds, 13–14 (trans) 5–6 (cis) and 17–18 (cis).

The primary prostaglandins PGG and PGH, (the endoperoxides) are intermediates in the synthesis of others. Only 5 PGs are widely distributed in the body. They are PGD₂, PGE₂, PGF₂ and PGI₂ and thromboxane A₂. Structure of PGF₂ is shown in Fig. 13.2-B. Thromboxanes have 6 membered oxane ring (Fig. 13.2-C).

Biosynthesis of Prostaglandins
Prostaglandins are derived from the PUFA, the three series being derived from the following fatty acids.
1 series (1 double bond) –from Linoleic acid
2 series (2 double bonds)–from Arachidonic acid
3 series (3 double bonds)–Eicosa penta-enoic

Naturally occurring PGs belong to the 2 series.
i. PGs are not stored as such; the precursor fatty acids are stored in membrane as phospholipids. The arachidonic acid is released by the action of phospholipase A₂ on phospholipids (Fig. 13.3).

ii. Synthesis is catalyzed by Prostaglandin H synthase (PGHS). It contains two separate enzyme activities, cyclooxygenase and peroxidase.

iii. PGG₂ and PGH₂ are formed as intermediates during the synthesis of other PGs. Specific enzymes convert PGH₂ to other prostaglandins (Fig. 13.3).

Regulation of Synthesis
iv. The phospholipase (PL) is activated by epinephrine, thrombin, angiotensin II, bradykinin and vasopressin. Steroids inhibit PL and prevent release of arachidonic acid from membranes (Fig. 13.3).

v. Cyclooxygenase is activated by catecholamines and inhibited by non-steroid anti-inflammatory drugs (NSAIDS). Aspirin acetylates serine in the active site and irreversibly inhibits the cyclooxygenase (Box 13.3).

vi. Cyclooxygenase is a "suicide" enzyme, self catalyzed destruction rapidly inactivates the enzyme (see suicide inhibition in Chapter 5). This would prevent excessive production of PGs.

vii. Cyclooxygenase exists in two different forms. COX-1, the constitutive form produces prostaglandins, that mediate gastric, renal and platelet functions. The inducible form mediates the inflammatory response.

viii. Prostaglandins have only very short half life, of about 30 seconds. They are inactivated by the 15-hydroxy-prostaglandin-dehydrogenase which converts 15-OH group to keto group (Fig. 13.3).

Mechanism of Action
Prostaglandins are local hormones. They function through G-protein coupled receptors (Chapter 44).
In most tissues, PGE increases cAMP (cyclic AMP) level. But in adipose tissue and in renal tubular cells, PGE lowers cAMP level. PGI activates adenyl cyclase and TXA inhibits it (Fig. 13.3).

Biological Actions and Clinical Applications

1. Effects on CVS
Prostacyclin or PGJ2 is synthesized by the vascular endothelium. Major effect is vasodilatation. It also inhibits platelet aggregation and has a protective effect on vessel wall against deposition of platelets. But any injury to the vessel wall would inhibit PGJ2 synthesis so that platelet aggregation occurs to promote thrombus formation.

Thromboxane (TXA2) is the main PG produced by platelets. The major effects are vasoconstriction and platelet aggregation. Prostacyclin and thromboxane are opposing in activity (Table 13.3.). Prostaglandins lower the blood pressure.

2. Effects on Ovary and Uterus
PGF2 stimulates the uterine muscles. Hence PGF2 may be used for medical termination of pregnancy. Yet another use is in inducing labor and arresting postpartum hemorrhage. PGs are involved in LH induced ovulation. In cattle, if PG is given, luteolysis takes place and animal goes into estrus. Better fertilization rate is achieved with timely artificial insemination.

3. Effects on Respiratory Tract
PGF is a constrictor of bronchial smooth muscle; but PGE is a potent bronchodilator. PGE series are used in aerosols for relieving bronchospasm.

4. Effects on Immunity and Inflammation
PGE2 and D2 produce inflammation by increasing capillary permeability. Erythema and wheal are produced at the site of injury. The anti-inflammatory effect of PG synthesis inhibitor (aspirin; cortisol) is explained in Box 13.3. Moreover, PGE2 reduces both T and B cell functions. PGE2 is a sleep promoting substance.

5. Effects on Gastrointestinal Tract
PGs in general inhibit gastric secretion and increase intestinal motility. The inhibitory effect on gastric secretion is used therapeutically in treatment of acid peptic disease. But diarrhea may be an unwanted side effect.

6. Metabolic Effects
The metabolic effects may be through the action of hormones by the modulating effect on cAMP production. Prostaglandin E2 decreases lipolysis, increases calcium mobilization from bone and glycogen synthesis.

Leukotrienes (LTs)
They are produced from arachidonic acid. The pathway is shown in Figure 13.4. LT B4 is produced in neutrophils; it is the most potent chemotactic agent (factor attracting cells to the inflammatory site). The number 4 denotes that there are 4 double bonds in the structure. The 12-lipo-oxygenase in platelets produces 12-HETE (hydroxy eicosa tetraenoic acid) and 15-lipo-oxygenase in eosinophils produce 15-HETE. The slow reacting substance of anaphylaxis (SRS-A) contains LTC4, LTD4 and LTE4 . They cause smooth muscle contraction, constrict the bronchioles, increase capillary permeability, activate leukocytes and produce vasoconstriction. SRS is the mediator of hypersensitivity reactions such as asthma.

Lipoxins
They are a group of compounds produced by leukocytes. They are conjugated tetraenes. They are formed by sequential action of 5 and 15-lipo-oxygenase. LXA4 is the most common variety (Fig. 13.4). It is anti-inflammatory and decreases immune response.

SYNTHESIS OF COMPOUND LIPIDS
Structures of lecithin, cephalin, phosphatidyl inositol, plasmalogen, sphingosine, ceramide and sphingomyelin are shown in Chapter 7. Their metabolisms are described below.

Synthesis of Glycerophosphatides
Phosphatidic acid is an important intermediate in the synthesis of phosphoglycerides as well as
triacylglycerol. The phosphatidic acid itself may be formed from glycerol-3-phosphate or dihydroxy acetone phosphate (Fig.11.17). The synthesis of glycerophospholipids can occur either by activation into CDP-choline and CDP-ethanolamine or by formation of active diacylglycerol, CDP-diacylglycerol.

**Synthesis of Phosphatidyl Inositol**
In the CDP-diacyl glycerol pathway, phosphatidic acid first reacts with CTP to form CDP diacylglycerol. The CDP diacylglycerol can react with the alcoholic group of serine or inositol to form the corresponding phosphoglyceride and releasing CMP. The phosphatidyl inositol undergoes further phosphorylation by a specific kinase to form phosphatidyl inositol diphosphate (PIP2) which acts as signal transducer.

**Synthesis of Phosphatidyl Choline**
The major pathway for lecithin and cephalin synthesis, especially in liver and brain, involves the activation of choline or ethanolamine to phosphorylated derivative and then to form the CDP derivative (Fig. 13.6). Finally phosphocholine or phosphoethanolamine is transferred to diacylglycerol to form the corresponding phospholipid. Phosphatidyl serine can also be formed from phosphatidyl ethanolamine by a base transfer reaction (Fig. 13.6).

The addition of an arachidonic acid to the 2nd carbon of glycerol may be achieved by removal of the fatty acid already present by the action of phospholipase A2. This is followed by addition of an arachidonic acid molecule from arachidonyl-CoA by a specific acyl transferase or from another phospholipid molecule by LLAT (Lecithin-lysolecithin acyl transferase) (Fig. 13.5). For the formation of the pulmonary surfactant, dipalmitoyl lecithin, palmitic acid is added by similar reactions. Lysophospholipids are often the sources of fatty acids for such purposes. Lung surfactants are described in Chapter 7.

**Cardiolipin**
It is formed by reaction between CDP diacylglycerol and glycerol-3-phosphate.

**Plasmalogens**
They are formed from dihydroxy acetone phosphate by acylation and addition of choline or ethanolamine.
Chapter 13; MCFA, PUFA, Prostaglandins and Compound Lipids

Fig. 13.7. Synthesis of ceramide

Fig. 13.8. Synthesis of cerebrosides

Fig. 13.9. Synthesis of gangliosides

Yet another important enzyme acting on lecithin is LCAT which transfers a PUFA from 2nd carbon of glycerol to cholesterol forming lysolecithin and cholesterol ester (see Chapters 12 and 25).

Synthesis of Sphingolipids

Sphingolipids may be of two types; phospho sphingolipids and glycosphingolipids. Both types are important components of biomembranes as well as the brain. The most important phospho-sphingolipid is sphingomyelin. The glycosphingolipids may be cerebrosides, ceramide oligosaccharides and gangliosides. Ceramide is the basic structural unit of all sphingolipids.

Synthesis of Ceramide

It is formed from sphingosine and fatty acyl CoA. Sphingosine is formed in the endoplasmic reticulum from palmitoyl CoA and serine in the presence of pyridoxal phosphate (Fig. 13.7).

Synthesis of Sphingomyelin

Ceramide + CDP choline $\rightarrow$ Sphingomyelin + CMP

Ceramide reacts with CDP choline to form sphingomyelin; the reaction being catalyzed by the
**Synthesis of Cerebrosides**

The most common ones are glucocerebroside and galactocerebroside. The transfer of one $\beta$-glycosidic bond between the C1 of the hexose and C1 of ceramide is catalyzed by specific glycosyl transferases. Galactocerebroside is an important component of brain lipids (Fig. 13.8).

**Gaucher’s Disease**

This is an inborn error of metabolism due to failure of degradation of glucocerebrosides. The enzyme beta glucosidase is deficient in this condition (Table 13.4).

**Synthesis of Sulfatides**

Cerebroside sulfatides are sulphuric acid esters of cerebrosides and the major sulfolipid of brain is galactocerebroside-3-sulfate (Fig. 13.8). PAPS is phosphoadenosine phosphosulfate or active sulfate formed from sulfur containing amino acids (Chapter 15). The enzyme is a sulfotransferase.

**Synthesis of Gangliosides**

This group of glycosphingolipids contains one or more sialic acid residues. They are present in high concentrations in the CNS and also on surface of membranes. The major gangliosides of brain are GM1, GM2, and GM3. For ganglioside synthesis, the active form of NANA (N-acetyl neuraminic acid) used is its CMP derivative. The NANA is attached by the hydroxyl group of its 2nd carbon to the 3rd hydroxyl group of sugars. The synthesis is shown in Figure 13.9.

A specific ganglioside on intestinal mucosal cell binds to the b subunit of the cholera toxin when the a subunit enters the cell. It keeps the level of cellular cAMP raised by inhibition of GTPase activity of the G protein (Chapter 44). Gangliosides also act as receptors for other toxins like tetanus toxin, and toxins of viral pathogens. Gangliosides contribute to stability of paranodal junctions and ion channel clusters in myelinated nerve fibers. Autoantibodies to GM1 and GD1a disrupt lipid rafts, paranodal or nodal structures, and ion channel clusters in peripheral motor nerves.

**Tay-Sachs Disease**

This is an inborn error of metabolism due to failure of degradation of gangliosides. The enzyme hexosaminidase A is deficient in this condition (Table 13.4).

**Lipid Storage Diseases (Sphingolipidoses)**

i. They are otherwise called as Sphingolipidoses. They form a group of lysosomal storage diseases.
ii. The sphingolipids are normally catabolized by a series of bond specific lysosomal hydrolases like alpha and beta glucosidases, galactosidase, neuraminidase, hexosaminidase and aryl sulfatase (for sulfate ester hydrolysis) (Fig. 13.10).

iii. The diseases result from failure of breakdown of a particular sphingolipid due to deficiency of a single enzyme.

iv. The children afflicted by these diseases are severely retarded mentally and seldom survive for long.

v. All these diseases can be diagnosed prenatally by amniocentesis and culture of amniotic fluid cells. Since the children born with these diseases will have serious mental deficits, the pregnancy may be terminated. Replacement of deficient enzyme has been tried in Gaucher’s disease, with limited success.

vi. The common features of lipid storage diseases include:
   a. Only one type of sphingolipid accumulates.
   b. Rate of synthesis of the lipid is normal, only degradation is affected.
   c. The extent of the enzyme deficiency is the same in all tissues. A chart showing the salient features of the disease is given in Table 13.4.

Multiple Sclerosis
It is a demyelinating disease. Phospholipids (ethanol amine plasmalogen and sphingolipids) are lost from white matter of the central nervous system. Cerebrospinal fluid contains increased quantity of phospholipids.

The main role of amino acids is in the synthesis of structural and functional proteins. Unlike carbohydrates and fats, there is no storage form of proteins in the body. A 70 kg man has an average protein turnover rate of 400 g per day (same amount synthesized and same amount broken down). The non-essential amino acids are either derived from the diet or synthesized in the body. The essential amino acids are obtained from the diet. Even if one is deficient, protein synthesis cannot take place. The body amino acid pool is always in a dynamic steady state. In an adult, the rate of synthesis of proteins balances the rate of degradation, so that nitrogen balance is maintained (Fig. 14.1).

**DIGESTION OF PROTEINS**

The dietary proteins are denatured on cooking and therefore more easily digested. All these enzymes are hydrolases (class 3 enzymes) in nature. Proteolytic enzymes are secreted as inactive zymogens which are converted to their active form in the intestinal lumen. This would prevent autodigestion of the secretory acini. The proteolytic enzymes include:

1. **Endopeptidases.** They act on peptide bonds inside the protein molecule, so that the protein becomes successively smaller and smaller units. This group includes Pepsin, Trypsin, Chymotrypsin, and Elastase.

2. **Exopeptidases,** which act at the peptide bond only at the end region of the chain. This group includes:

**Fig. 14.1.** Overview of metabolism of amino acids
Fig. 14.2. Action of proteases. The enzyme hydrolyses the peptide bond at the site of arrow

2-A. Carboxypeptidase acts on the peptide bond only at the carboxy terminal end on the chain.

2-B. Aminopeptidase, which acts on the peptide bond only at the amino terminal end on the chain.

A summary of their actions is shown in Figure 14.2. The digestion of protein is effected by enzymes in:
A. Stomach
B. Pancreas and
C. Intestinal cells

A. Gastric Digestion of Proteins
In the stomach, hydrochloric acid is secreted (Chapter 26). It makes the pH optimum for the action of pepsin and also activates pepsin. The acid also denatures the proteins.

1. Rennin
Rennin otherwise called Chymosin, is active in infants and is involved in the curdling of milk.

(Box 14.1). It is absent in adults. Milk protein, casein is converted to paracasein by the action of rennin. This denatured protein is easily digested further by pepsin.

2. Pepsin
It is secreted by the chief cells of stomach as inactive pepsinogen. The conversion of pepsinogen to pepsin is brought about by removal of 44 amino acids from the N-terminal end, by the hydrochloric acid. The optimum pH for activity of pepsin is around 2. Pepsin is an endopeptidase, (Table 14.1). Pepsin catalyses hydrolysis of the bonds formed by carboxyl groups of Phe, Tyr, Trp and Met. By the action of pepsin, proteins are broken into proteoses and peptones.

B. Pancreatic Digestion of Proteins
The optimum pH for the activity of pancreatic enzymes (pH 8) is provided by the alkaline bile and pancreatic juice. The secretion of pancreatic juice is stimulated by the peptide hormones, Cholecystokinin and Pancreozymin.

Pancreatic juice contains the important endopeptidases, namely Trypsin, Chymotrypsin, Elastase and Carboxypeptidase.

These enzymes are also secreted as zymogens (trypsinogen, chymotrypsinogen and pro-elastase), so that the pancreatic acinar cells are not autolysed. All the three are serine proteases, i.e. the active centers of these enzymes contain serine residues.

3. Trypsin
Trypsinogen is activated by enterokinase (enteropeptidase) present on the intestinal microvillus
membranes. Once activated, the trypsin activates other enzyme molecules. Trypsin is activated by the removal of a hexapeptide from N-terminal end. Trypsin catalyses hydrolysis of the bonds formed by carboxyl groups of Arg and Lys.

**Acute pancreatitis:** Premature activation of trypsinogen inside the pancreas itself will result in the autodigestion of pancreatic cells. The result is acute pancreatitis. It is a life-threatening condition.

4. **Chymotrypsin**
Trypsin will act on chymotrypsinogen, in such a manner that A, B and C peptides are formed. These 3 segments are approximated, so that the active site is formed. Thus, selective proteolysis produces the catalytic site.

5. **Carboxypeptidases**
Trypsin and chymotrypsin degrade the proteins into small peptides; these are further hydrolysed into dipeptides and tripeptides by carboxypeptidases present in the pancreatic juice. The procarboxypeptidase is activated by trypsin. They are metallo-enzymes requiring zinc.

C. **Intestinal Digestion of Proteins**
Complete digestion of the small peptides to the level of amino acids is brought about by enzymes present in intestinal juice (succus entericus). The luminal surface of intestinal epithelial cell contains the following enzymes:

6. **Leucine aminopeptidase**
It releases the N-terminal basic amino acids and glycine.

7. **Proline amino peptidase**
It removes proline from the end of polypeptides.

8. **Dipeptidases and tripeptidases**
They will bring about the complete digestion of proteins; their specificities are shown in Figure 14.2.

**ABSORPTION OF AMINO ACIDS**
The absorption of amino acids occurs mainly in the small intestine. It is an energy requiring process. These transport systems are carrier mediated and or ATP sodium dependent symport systems. There are 5 different carriers for amino acids:

1. Neutral amino acids (Alanine, Valine, Leucine, Methionine, Phenylalanine, Tyrosine, Isoleucine)
2. Basic amino acids (Lys, Arg) and Cysteine
3. Imino acids and Glycine
4. Acidic amino acids (Asp, Glu)
5. Beta amino acids (beta alanine).

**Meister Cycle (Gamma Glutamyl Cycle)**
In intestines, kidney tubules and brain, the absorption of neutral amino acids is effected by the gamma glutamyl cycle. The main role is played by the tripeptide glutathione (GSH) (gamma glutamyl cycle).
glutamyl cysteinyl glycine). It reacts with the amino acid to form gamma glutamyl amino acid. This is catalyzed by gamma glutamyl transferase. The glutamyl amino acid is then cleaved to give the free amino acid. The net result is the transfer of an amino acid across the membrane (Fig. 14.3). The transport of one molecule of amino acid and regeneration of GSH requires 3 molecules of ATP.

Food Allergy
Dipeptides and tripeptides can enter the brush border of mucosal cells; they are immediately hydrolysed into single amino acids. They are then transported into portal vein. Rarely, larger molecules may pass paracellularly (between epithelial cells) and enter blood stream. These are immunogenic, causing antibody reaction, leading to food allergy. Caveolae mediated transcytosis has been shown to transport IgA molecules intact across the mucosal cell.

Clinical Applications
1. The deficiency of the enzyme 5-oxoprolinase leads to oxoprolinuria (pyroglutamic aciduria).

Box 14.2. Life Span of Proteins

The half-life of proteins is highly variable. Ornithine decarboxylase has only 11 minutes. Half life of hemoglobin depends on the life span of RBCs. The lens protein, Crystallin remains unchanged throughout the life of the organism. Damaged or defective proteins are prematurely degraded.

2. The allergy to certain food proteins (milk, fish) is believed to result from absorption of partially digested proteins.
3. Defects in the intestinal amino acid transport systems are seen in inborn errors of metabolism such as
   3-A. Hartnup’s disease (Chapter 17)
   3-B. Iminoglycinuria
   3-C. Cystinuria (Chapter 15)
   3-D. Lysinuric protein intolerance
   3-E. Oasthouse syndrome.
4. Partial gastrectomy, pancreatitis, carcinoma of pancreas and cystic fibrosis may affect the digestion and absorption of proteins.
5. Protein losing enteropathy: There is an excessive loss of serum proteins through the gastrointestinal tract.

Intracellular Protein Degradation
All proteins in the body are constantly being degraded. Half-life (t 1/2) of a protein is the time taken to lower its concentration to half of the initial value. General tissue proteins have half
lives of few hours. Key enzymes have half lives usually of about few minutes only (See Box 14.2). PEST sequence (areas rich in proline, glutamate, serine and threonine) on a protein will give an inherent message to breakdown that protein very quickly.

Extracellular particles or proteins are taken by endocytosis and are fused with lysosomes (Chapter 2). Intracellular proteins are also ultimately broken down by lysosomes.

**Cathepsins**
In the phagolysosomes, the particles are broken down by enzymes known as cathepsins. The term cathepsin is a Greek word, meaning ‘to digest’. Cathepsins are 18 in number, designated as A to T. Most of them are active at pH around 3 to 5.

**Ubiquitin**
Intracellular protein breakdown also occurs independent of lysosomes. This involves ubiquitin. It is so named, because it is seen in all cells abundantly. It is a small protein with 76 residues (mol.wt., 8.5 kDa). Ubiquitin is attached with proteins with the help of 3 enzymes, E1 (activating enzyme), E2 (ligase) and E3 (transferase). Congenital defect in E3 has been implicated in the genesis of Angelman syndrome and von Hippel-Lindau syndrome.

**Proteasomes**
Ubiquitin attached proteins are immediately broken down inside the proteasomes of the cells. The proteasomal assembly has a central cylindrical hollow core. Ubiquitin-tagged proteins are taken into this barrel, and surrounding proteolytic enzymes digest the protein into small oligopeptides of 5-6 amino acids length (Box 14.2). Ciechanover, Hershko and Rose were awarded Nobel Prize in 2004 for their discovery of ubiquitin-mediated protein degradation.

**Inter-organ Transport of Amino Acids**
In plasma, all amino acids are seen at a level roughly of 1 mg/dl, except glutamic acid and glutamine, which are present in higher concentrations (each about 10 mg/dl). Breakdown of muscle protein is the source of amino acids for tissues while liver is the site of disposal (Figs 14.4 and 14.5).

**In Fasting State**
The muscle releases mainly alanine and glutamine of which alanine is taken up by liver and glutamine by kidneys (Fig. 14.4). Liver removes the amino group and converts it to urea and the carbon skeleton is used for gluconeogenesis. Students should also refer glucose-alanine cycle, in Chapter 9, under gluconeogenesis (Fig. 9.30). The brain predominantly takes up branched chain amino acids.

**In the Fed State**
Amino acids absorbed from the diet are taken up by different tissues (Fig. 14.5). Both muscle and brain take up branched chain amino acids, and release glutamine and alanine. The glutamine is delivered to kidneys to aid in regulation of acid–base balance while alanine is taken up by liver.

**GENERAL METABOLISM OF AMINO ACIDS**
1. The **anabolic reactions** where proteins are synthesized.
2. Synthesis of specialized products such as heme, creatine, purines and pyrimidines.
3. The **catabolic reactions** where dietary proteins and body proteins are broken down to amino acids.
4. Transamination: amino group is removed to produce the carbon skeleton (keto acid). The amino group liberated as ammonia is detoxified and excreted as urea.
5. The carbon skeleton is used for synthesis of non-essential amino acids.
6. It is also used for gluconeogenesis or for complete oxidation.
7. Other minor metabolic functions like conjugation, methylation, amidation, etc. Table 14.1 gives a summary of amino acid metabolism. The amino acid pool in the body is shown in Figure 14.6.

**FORMATION OF AMMONIA**
The sources and fate of ammonia are shown in Figure 14.7. The first step in the catabolism of amino
acids is to remove the amino group as ammonia. This is the major source of ammonia. However, small quantities of ammonia may also be formed from catabolism of purine and pyrimidine bases.

Ammonia is highly toxic especially to the nervous system. Detoxification of ammonia is by conversion to urea and excretion through urine.

A. Transamination

i. Transamination is the exchange of the alpha amino group between one alpha amino acid and another alpha keto acid, forming a new alpha amino acid.

\[
\text{amino acid } 1 + \text{keto acid } 2 \rightarrow \text{ amino acid } 2 + \text{keto acid } 1
\]

ii. As an example, amino group is interchanged between alanine and glutamic acid (Fig. 14.8). In almost all cases, the amino group is accepted by alpha ketoglutaric acid so that glutamic acid is formed.

iii. The enzymes catalysing the reaction as a group are known as amino transferases. These enzymes have pyridoxal phosphate as prosthetic group (Fig. 14.8). The reaction is readily reversible.

Biological Significance of Transamination

1. First step of catabolism
In this first step, ammonia is removed, and the carbon skeleton of the amino acid enters into catabolic pathway.

2. Synthesis of nonessential amino acids
By means of transamination, all nonessential amino acids can be synthesized by the body from keto acids available from other sources. For example, pyruvate can be transaminated to synthesize alanine. Similarly oxaloacetate produces aspartic acid. Alpha keto glutarate is transaminated to form glutamic acid. Those amino acids, which cannot be synthesized in this manner, are therefore essential; they should be made available in the food (See Box 3.1 for essential amino acids).

3. Interconversion of amino acids
If amino acid no.1 is high and no.2 is low; the amino group from no.1 may be transferred to a
keto acid to give amino acid no. 2 to equalize the quantity of both. This is called equalization of quantities of nonessential amino acids.

Exceptions
Lysine, threonine and proline are not transaminated. They follow direct degradative pathways.

Clinical Significance of Transamination
Aspartate amino transferase (AST) and Alanine amino transferase (ALT) are induced by glucocorticoids which favor gluconeogenesis. AST and ALT are markers of liver injury. Their clinical importance is given in Chapters 23 and 26.

B. Trans-deamination
1. The amino group of most of the amino acids is released by a coupled reaction, transdeamination, that is transamination followed by oxidative deamination.
2. Transamination takes place in the cytoplasm of all the cells of the body; the amino group is transported to liver as glutamic acid which is finally oxidatively deaminated in the mitochondria of hepatocytes.
3. Thus, the two components of the reaction are physically far away, but physiologically they are coupled. Hence, the term trans-deamination (Fig. 14.9).

Oxidative Deamination of Glutamate
Only liver mitochondria contain glutamate dehydrogenase (GDH) which deaminates glutamate to alpha keto glutarate plus ammonia. So, all amino acids are first transaminated to glutamate, which is then finally deaminated (transdeamination) (Fig. 14.9). Amino acids are deaminated at the rate of about 50 - 70 g per day.

During the transamination reaction the amino group of all other amino acids is funnelled into glutamate. Hence, the glutamate dehydrogenase reaction is the final reaction which removes the amino group of all amino acids (Fig. 14.9). It needs NAD⁺ as co-enzyme. (NADP can also act as a co-enzyme). It is an allosteric enzyme; it is activated by ADP and inhibited by GTP.

The hydrolysis of glutamine also yields NH₃ but this occurs mainly in the kidney where the NH₄⁺ excretion is required for acid base regulation.

Minor Pathways of Deamination
1. L-amino acid oxidase can act on all amino acids except hydroxy amino acids and dicarboxylic amino acids. It uses FMN as co-enzyme. The peroxide formed in this reaction is decomposed by catalase in the peroxisomes (Fig. 14.10).
2. D-amino acid oxidase can oxidise glycine and any D amino acid that may be formed by bacterial metabolism. It uses FAD as co-enzyme.
3. Ammonia may be formed in the body through minor reactions like oxidation of monoamines by MAO (monoamine oxidase) (Chapter 17, under Tyrosine metabolism).

Nonoxidative Deaminations
1. Dehydratases act on hydroxy amino acids to remove ammonia from the following amino acids:
   1-A. Serine will give rise to pyruvate (Chapter 15)
   1-B. Threonine is converted to alpha keto butyric acid.
2. Desulfhydrase: Cysteine undergoes deamination and simultaneous trans-sulphuration to form pyruvate. (Chapter 15).

Box 14.3. Mammals excrete Ammonia as Urea; but Birds Excrete Ammonia as Uric Acid

Millions of “gooney” birds nest on some islands of Pacific Ocean, off the coast of Peru. Over the centuries, their droppings formed big hills. These “guano” deposits, containing mainly uric acid, is now being exploited commercially as fertiliser containing nitrogen.

#### DISPOSAL/DETOXIFICATION OF AMMONIA

**1. First line of Defense (Trapping of ammonia)**

Being highly toxic, ammonia should be eliminated or detoxified, as and when it is formed. Even very minute quantity of ammonia may produce toxicity in central nervous system. But, ammonia is always produced by almost all cells, including neurons. The intracellular ammonia is immediately trapped by glutamic acid to form glutamine, especially in brain cells (Fig. 14.11). The glutamine is then transported to liver, where the reaction is reversed by the enzyme glutaminase (Fig. 14.11). The ammonia thus generated is immediately detoxified into urea. Aspartic acid may also undergo similar reaction to form asparagine (Chapter 16).

**2. Transportation of Ammonia**

Inside the cells of almost all tissues, the transamination of amino acids produce glutamic acid. However, glutamate dehydrogenase is available only in the liver. Therefore, the final deamination and production of ammonia is taking place in the liver (Fig. 14.9). Thus, glutamic acid acts as the link between amino groups of amino acids and ammonia. The concentration of glutamic acid in blood is 10 times more than other amino acids. **Glutamine** is the transport forms of ammonia from brain and intestine to liver; while alanine is the transport form from muscle.

**3. Final disposal**

The ammonia from all over the body thus reaches liver. It is then detoxified to urea by liver cells, and then excreted through kidneys. **Urea is the end product of protein metabolism.**

Since mammals including human beings excrete amino nitrogen mainly as urea, they are referred to as ureotelic. Fishes excrete ammonia as such (ammoneotelic) while birds and reptiles as uric acid (uricotelic) (Box 14.3).

Although Ammonia is toxic and has to be immediately detoxified, in kidney cells, ammonia is purposely generated from glutamine with the help of glutaminase. This is for buffering the acids, and maintaining acid-base balance (see Fig. 29.5).

### UREA CYCLE

In 1773, Rouelle isolated urea from urine. Frederic Wohler in 1828 obtained urea by boiling an aqueous solution of ammonium cyanate. The urea cycle is the first metabolic pathway to be elucidated (1932). The cycle is known as Krebs–Henseleit urea cycle. As ornithine is the first member of the reaction, it is also called as **Ornithine cycle.**

The two nitrogen atoms of urea are derived from two different sources, one from ammonia and the other directly from the alpha amino group of aspartic acid.

#### Step 1. Formation of Carbamoyl Phosphate

One molecule of ammonia condenses with CO₂ in the presence of **two molecules of ATP** to form...
carbamoyl phosphate. The reaction is catalysed by the mitochondrial enzyme carbamoyl phosphate synthetase-I (CPS-I) (Figs 14.12 and 14.13, Step 1). An entirely different cytoplasmic enzyme, carbamoyl phosphate synthetase-II, (CPS-II) is involved in pyrimidine nucleotide synthesis (Chapter 39). The differences of CPS-I and II are shown in Table 14.2. CPS-I reaction is the rate-limiting step in urea formation. It is irreversible and allosterically regulated.

**Step 2. Formation of Citrulline**
The second reaction is also mitochondrial. The carbamoyl group is transferred to the NH$_2$ group of ornithine by ornithine transcarbamoylase (OTC) (Figs 14.12 and 14.13, step 2). The citrulline leaves the mitochondria and further reactions are taking place in cytoplasm. Citrulline is neither present in tissue proteins nor in blood; but it is present in milk.

**Step 3. Formation of Argininosuccinate**
One molecule of aspartic acid adds to citrulline forming a carbon to nitrogen bond which provides the 2nd nitrogen atom of urea. Argininosuccinate synthetase catalyses the reaction (Figs 14.12 and 14.13, step 3). This needs hydrolysis of ATP to AMP level, so two high energy phosphate bonds are utilized. The PPi is an inhibitor of this step.

**Step 4. Formation of Arginine**
Argininosuccinate is cleaved by argininosuccinate lyase (argininosuccinase) to arginine and fumarate (Figs 14.12 and 14.13, step 4). The enzyme is inhibited by fumarate. But this is avoided by the cytoplasmic localization of the enzyme. The fumarate formed may be funnelled into TCA cycle to be converted to malate and then to oxaloacetate to be transaminated to aspartate (Fig. 14.13). Thus the urea cycle is linked to TCA cycle through

---

**Fig. 14.13. Urea cycle and its relation with citric acid cycle**

---

**Fig. 14.14. NAG synthesis and breakdown**
fumarate. The 3rd and 4th steps taken together may be summarized as:

\[
\text{Citrulline + aspartate} \rightarrow \text{Arginine + fumarate}
\]

A similar reaction of donation of amino group by aspartate takes place in purine nucleotide synthesis also (Chapter 39).

**Step 5. Formation of Urea**
The final reaction of the cycle is the hydrolysis of arginine to urea and ornithine by arginase (Figs 14.12 and 14.13, step 5). The ornithine returns to the mitochondria to react with another molecule of carbamoyl phosphate so that the cycle will proceed. Thus, ornithine may be considered as a catalyst which enters the reaction and is regenerated.

**Energetics of Urea Cycle**
The overall reaction may be summarized as:

\[
\text{NH}_3 + \text{CO}_2 + \text{Aspartate} \rightarrow \text{Urea} + \text{fumarate}
\]

During these reactions, 2 ATPs are used in the 1st reaction. Another ATP is converted to AMP + PPi in the 3rd step, which is equivalent to 2 ATPs. The urea cycle consumes 4 high energy phosphate bonds. However, fumarate formed in the 4th step may be converted to malate. Malate when oxidised to oxaloacetate produces 1 NADH equivalent to 2.5 ATP. So net energy expenditure is only 1.5 high energy phosphates. The urea cycle and TCA cycle are interlinked, and so, it is called as "urea bicycle".

**Regulation of the Urea Cycle**

1. **Coarse Regulation**
The enzyme levels change with the protein content of diet. During starvation, the activity of urea cycle enzymes is elevated to meet the increased rate of protein catabolism.

2. **Fine Regulation**
The major regulatory step is catalyzed by CPS-I where the positive effector is N-acetyl glutamate (NAG). It is formed from glutamate and acetyl CoA (Fig. 14.14). Arginine is an activator of NAG synthase.

3. **Compartmentalization**
The urea cycle enzymes are located in such a way that the first two enzymes are in the mitochondrial matrix. The inhibitory effect of fumarate on its own formation is minimized because argininosuccinate lyase is in the cytoplasm, while fumarase is in mitochondria (Fig. 14.13).

**Disorders of Urea Cycle**
Deficiency of any of the urea cycle enzymes would result in hyperammonemia. When the block is in one of the earlier steps, the condition is more severe, since ammonia itself accumulates. Deficiencies of later enzymes result in the accumulation of other intermediates which are less toxic and hence symptoms are less. As a general description, disorders of urea cycle are characterized by hyperammonemia, encephalopathy and respiratory alkalosis. Clinical symptoms include vomiting, irritability, lethargy and severe mental retardation. Infants appear normal at birth, but within days progressive lethargy sets in. Treatment is more or less similar in the different types of disorders. Low protein diet with sufficient arginine and energy by frequent feeding can minimize brain damage since ammonia levels do not increase very high (Table 14.3).

1. **Carbamoyl Phosphatase synthetase I deficiency** (Hyperammonemia type I) is comparatively rare and is characterized by severe hyperammonemia. A variant of the condition is seen in N acetyl glutamate synthetase.

2. **Ornithine transporter deficiency** is characterized by hyperornithinemia, hyperammonemia and homocitrullinuria (HHH syndrome). Ornithine has to be transported into the mitochondria and citrulline has to come out since urea cycle is compartmentalized. Ornithine accumulates in the cytoplasm. Since ornithine is not available in the mitochondria, lysine is carbamoylated to form homocitrulline.

3. **Ornithine transcarbamoylase deficiency** is the only urea cycle disorder which is inherited as an X-linked trait. Hyperammonemia Type II is characterized by OTC deficiency. Mothers also have hyperammonemia and an aversion to high protein diet. Elevated levels of ammonia are associated with high glutamine levels in CSF and blood.

4. **Argininosuccinate synthetase deficiency** is characterized by hyperammonemia, citrullinemia and citrullinuria (1-2 g/day). CSF citrulline levels are also elevated.

5. **Argininosuccinate lyase deficiency** leads to argininosuccinicacidemia and therefore metabolic acidosis. Hyperammonemia is less severe and argininosuccinatemia is elevated in CSF and excreted in urine. A typical clinical feature is friable tufted hair (trichorrhexis nodosa).

6. **Arginase deficiency** is the mild variety with accumulation and excretion of arginine (hyperargininemia and argininuria) are seen. Symptoms appear by 2-4 years of age.

The accumulation of ammonia in blood (normally less than 40 mg/dl or 30-60 micromol/L) and body
fluids results in toxic symptoms. Nowadays, defects in enzymes of urea cycle are detected in neonatal blood by tandem mass spectrometry.

**Brain is very sensitive to ammonia.** Different urea cycle disorders are shown in Table 14.3. Child may be put on a low protein diet and frequent small feeds are given. Attempts may be made to eliminate the amino nitrogen in other forms, e.g. as hippuric acid (Benzoyl conjugate of glycine) or phenyl acetyl glutamine. Gene therapy is in experimental stage for treating urea cycle disorders.

Since **Citulline** is present in significant quantities in milk, breast milk is to be avoided in citrullinemia.

### Hepatic Coma (Acquired Hyperammonemia)
In diseases of the liver, hepatic failure can finally lead to hepatic coma and death. Hyperammonemia is the characteristic feature of liver failure. The condition is also known as portal systemic encephalopathy. Normally the ammonia and other toxic compounds produced by intestinal bacterial metabolism are transported to liver by portal circulation and detoxified by the liver. But when there is portal systemic shunting of blood, the toxins bypass the liver and their concentration in systemic circulation rises.

The signs and symptoms are mainly pertaining to CNS dysfunction (altered sensorium, convulsions), or manifestations of failure of liver function (ascites, jaundice, hepatomegaly, edema, hemorrhage, spider naevi).

The management of the condition is difficult. A low protein diet and intestinal disinfection (bowel clearing and antibiotics), withholding hepatotoxic drugs and maintenance of electrolyte and acid-base balance are the main lines of management.

Chapter 14; General Amino Acid Metabolism (Urea Cycle, One Carbon Metabolism)

Fig. 14.16. Summary of one-carbon metabolism; THFA = tetrahydrofolic acid

Urea Level in Blood
In clinical practice, blood urea level is taken as an indicator of renal function. The normal urea level in plasma is from 20 to 40 mg/dl. Blood urea level is increased when renal function is inadequate. Details of causes of uremia is given in Chapter 27. Urea level in blood may be theoretically increased when protein intake is very high. However in usual conditions, this will be only within the upper limit of the normal values.

Urinary excretion of urea is 15 to 30 g/day (6-15 g nitrogen/day). This corresponds to the breakdown of 40 to 80 g of proteins per day. Urea constitutes 80% of urinary organic solids.

Fig. 14.17. Synthesis of thymidyllic acid

ONE-CARBON METABOLISM
One-carbon (1C) groups play a pivotal role in donating carbon atoms for synthesis of different types of compounds. The different one-carbon groups of the 'one-carbon pool' of the body are:

1. Formyl group
2. Formimino group
3. Methenyl group
4. Hydroxymethyl group
5. Methylene group
6. Methyl group (see Table 14.4).

The one-carbon groups, except methyl group, are carried by tetrahydrofolic acid (THFA). THFA is produced from folic acid (Chapter 34). N5 and N10 atoms of THFA carry the one-carbon groups. The attachment of methylene (—CH2—) group is shown in Figure 14.15.

Generation of One-Carbon Groups
The one-carbon groups are contributed to the one-carbon pool by amino acids.

1. Serine to glycine (Serine hydroxymethyl transferase reaction, Fig.15.1) is the primary contributor for methylene THFA.
2. Glycine cleavage system also produces methylene groups (Fig. 15.3).
3. Histidine contributes to N5-formimino THFA through FIGLU (step 4, Fig.16.8).
4. Tryptophan donates formyl-THFA (step 1, Fig.17.8).
5. Choline and betaine are donors of hydroxy methyl groups (Chapter 15). As serine is converted to choline, 3 one-carbon units are used up. During the conversion of choline to glycine, these methyl groups are recovered (Chapter 15). Hence, this pathway is called the "salvage pathway" for one-carbon units.

Interconversion of One-Carbon Groups
The different one-carbon groups are interconvertible as shown in Figure 14.16. All one-carbon units are
From methyl-THFA, the B12 co-enzyme accepts the methyl group to form methyl cobalamin. It then transfers the methyl group to homocysteine to form methionine. This is one of the few reactions in human metabolism, where B12 acts as a co-enzyme (Fig. 14.16). In B12 deficiency, deficiency of folic acid is also observed; this is because, the transfer of methyl group from methyl-THFA does not occur. THFA is not regenerated; this is called folate trap.

Utilization of One-carbon groups
A summary of the generation and utilization of one-carbon group is shown in Figure 14.18. The one-carbon units are used for synthesis of the following compounds:
1. C2 of purine
2. Formylation of methionyl tRNA
3. C8 of purine
4. Glycine (Fig. 15.1)
5. Serine
6. Choline (Fig. 15.12)
7. Deoxy TMP (Fig. 14.17).
8. Transmethylation reactions including creatine, choline and epinephrine synthesis
9. Excreted as carbon dioxide
CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Glycine
2. Creatine, creatine phosphate and creatinine
3. Serine, Choline, Selenocysteine
4. Alanine
5. Methionine
6. Transmethylation reactions
7. Cysteine
8. Glutathione
9. Homocysteine and homocystinurias
10. Cystinosis
11. Cystathioninuria

GLYCINE (GLY) (G)
It is the simplest amino acid. It is non-essential and is glucogenic. Glycine is formed:
1. **From serine.** The beta carbon of serine is channeled into the one carbon pool, carried by THFA (tetra hydro folic acid). The alpha carbon of serine becomes the alpha carbon of glycine (Fig. 15.1).
2. **From threonine** by the activity of threonine aldolase (Fig. 15.2).

### 3. From glycine synthase.
Glycine can be synthesized by the glycine synthase reaction from CO$_2$, NH$_3$ and one carbon unit. This is the reversal of the glycine cleavage system. It is a multi-enzyme complex. It needs the co-enzymes, NAD, lipoamide, tetrahydrofolic acid and pyridoxal phosphate (Fig. 15.3).

### 4. Glycine amino transferase
Can catalyze the synthesis of glycine from glyoxylate and glutamate or alanine. This reaction strongly favors synthesis of glycine.

**Utilization of Glycine**

1. **Glycine cleavage system**
Glycine undergoes oxidative deamination (reversal of glycine synthase) to form NH$_3$, CO$_2$ and the one-carbon unit methylene THFA (Fig. 15.3). This pathway is the major catabolic route for glycine. The glycine cleavage system is a multi-enzyme complex consisting of:
   A. Glycine decarboxylase with pyridoxal phosphate
   B. Lipoamide containing amino methyl transferase

---

**Fig. 15.1.** Formation of glycine from serine

**Fig. 15.2.** Formation of glycine from threonine

**Fig. 15.3.** Glycine cleavage system
C. Methylene THFA synthesizing enzyme
D. NAD$^+$ dependent lipoamide dehydrogenase. This enzyme is anchored to the H-protein.

2. Glucogenic Pathway
Glycine is mainly channelled into the glucogenic pathway by getting first converted to serine. This is the reversal of serine hydroxy methyl transferase reaction (Fig. 15.1). The serine is then converted to pyruvate by serine dehydratase (Fig. 15.9).

3. Special Metabolic Functions of Glycine
Glycine may be used for the biosynthesis of the following compounds (Fig. 15.4):
   i. Creatine, creatine phosphate and creatinine
   ii. Heme
   iii. Purine nucleotides
   iv. Glutathione
   v. Conjugating agent
   vi. Neurotransmitter

4. Creatine and Creatine Phosphate
The word creatine is derived from the Greek term, kreas, which means flesh. Creatine constitutes about 0.5% of total muscle weight. It is synthesised from 3 amino acids, glycine, arginine and methionine.

A. First step: The amidino group of arginine is transferred to glycine to form guanido acetic acid, catalysed by amido transferase (Step 1, Fig. 15.5). It is seen in mitochondria of kidney and pancreas, but not in liver.

B. Second step: Guanido acetic acid is methylated by S-adenosyl methionine (SAM) by methyl transferase to form creatine. This methylation reaction takes place in liver.

C. Third step: Creatine is phosphorylated to creatine phosphate (Step 3, Fig. 15.5). The enzyme creatine kinase (CK) is present in muscle, brain and liver. The reaction needs hydrolysis of ATP. The stored creatine phosphate in the muscle serves as an immediate store of energy in the muscle. During muscle contraction, the energy is first derived from ATP hydrolysis. Thereafter, the ATP is regenerated by the hydrolysis of creatine phosphate (Fig. 15.6). This is called the Lohmann’s reaction (Lohmann, 1932).

D. Fourth step: The creatine phosphate may be converted to its anhydride, creatinine (Step 4, Fig. 15.5). It is a non-enzymatic spontaneous reaction. Creatinine is excreted in urine. The blood level of creatine and creatinine and

---

**Fig. 15.4. Overview of glycine metabolism**

**Fig. 15.5. Creatine metabolism**
Clinical Applications

i. Normal serum creatinine level is 0.7 to 1.4 mg/dl and serum creatine level is 0.2–0.4 mg/dl.

ii. Creatinine level in blood is a sensitive indicator of renal function (Chapter 27).

iii. Urine contains negligible amounts of creatine in normal males.

iv. But in muscular dystrophies, the blood creatine and urinary creatinine are increased.

v. The enzyme CK (creatine kinase) is elevated in myocardial infarction (Chapter 23).

5. Synthesis of Heme

The enzyme ALA synthase condenses glycine with succinyl CoA to form delta amino levulinic acid (ALA) (Chapter 21). It is the key enzyme of heme synthesis.

6. Synthesis of Purines

The whole molecule of glycine is incorporated into the purine ring (C4, C5 and N7) (Chapter 39).

7. Synthesis of Glutathione

Glutathione is a tripeptide formed from glutamic acid, cysteine and glycine. The functions of glutathione are described in the section on metabolism of cysteine.

8. Glycine as a Conjugating Agent

A. Bile acids. Glycine is used to conjugate bile acids, to produce bile salts. Glycocholic acid and glyco-chenodeoxy-cholic acid are the main conjugated bile acids (Fig. 12.20).

B. Benzoic acid. Benzoic acid is used in small amounts as preservative in foods. Glycine is used for detoxification of benzoic acid to form hippuric acid (Chapter 37).

9. Glycine as a Neurotransmitter

Glycine is seen in the brainstem and spinal cord. Glycine opens chloride specific channels. In moderate levels glycine inhibits neuronal traffic; but at high levels it causes over-excitation.

10. Glycine as a Constituent of Protein

Glycine is seen where the polypeptide chain bends or turns (beta bends or loops). In collagen, every 3rd amino acid is glycine.

Metabolic Errors in Relation to Glycine

1. Nonketotic Hyperglycinemia

It is due to defect in glycine cleavage system. Glycine level is increased in blood, urine and CSF. Severe mental retardation and seizures are seen. There is no effective management.
2. **Primary Hyperoxaluria**

i. Increased excretion of oxalates is observed (upto 600 mg/day, compared to a normal of 50 mg/day). The oxaluria is due to increased production of oxalates. It is an autosomal recessive trait.

ii. The disease is due to a **protein targeting defect**. Normally, the enzyme alanine glyoxalate amino transferase (No.1 in Fig. 15.7) is located in peroxisomes; but in these patients the enzyme is present in mitochondria (see also Box 41.1). So, enzyme is inactive.

iii. This leads to increased pool size of glyoxalate, and excess production of oxalate. Renal deposition of oxalates would cause nephrolithiasis, renal colic and hematuria. Extrarenal oxalosis may be seen in heart, blood vessels, bone, etc.

iv. **Type 2** primary hyperoxaluria is a milder condition causing only urolithiasis and results from deficient activity of cytoplasmic glyoxalate reductase (no. 2 in Fig. 15.7).

v. The principle of management is to increase oxalate excretion by increased water intake. Also try to minimise dietary intake of oxalates by restricting the intake of leafy vegetables, sesame seeds, tea, cocoa, beet-root, spinach, rhubarb, etc.

vi. In normal persons, oxalate can arise from
   a. glyoxalate metabolism,
   b. from ingestion of leafy vegetables
   c. from ascorbic acid degradation. The third source is minimal in human beings.

---

**SERINE (SER) (S)**

Serine is an aliphatic hydroxy amino acid. It is nonessential and glucogenic. Sources of serine are:

---

1. **Phosphoglycerate**: This is the major source of serine in the body. The steps involve dehydrogenation, transamination and removal of phosphate group (Fig. 15.8).

2. From **glycine** by reversal of serine hydroxy methyl transferase reaction (Fig. 15.1).

3. Serine may also be formed by transamination of hydroxy pyruvate with alanine.

Alanine + Hydroxy pyruvate → Pyruvate + Serine

---

**Catabolism of Serine**

1. Deamination to pyruvate catalyzed by serine dehydratase (Fig. 15.9).

2. Transamination to hydroxy pyruvate.

3. Serine is **glucogenic**.

---

**Metabolic Functions of Serine**

1. **One-carbon group**: Serine donates one-carbon group to the one-carbon pool. By the action of serine-hydroxymethyl-transferase enzyme, the one carbon group (methylene THFA) is removed from serine, and glycine is formed (Fig. 15.1).

2. **Cysteine**: Serine is used for the formation of cysteine (Fig. 15.15).

Serine+ Homocysteine → Cysteine+ Homoserine

3. **Alanine**: Serine is converted to alanine by dehydration followed by transamination.

4. Used for synthesis of phospholipids, such as phosphatidyl serine (Chapter 7).

5. **Drugs**: Serine analogues are used as drugs and they inhibit nucleotide synthesis (Fig. 15.11). **Azaserine** is an anti-cancer drug and **cycloserine** is an antituberculous drug.

---

**7. Choline Synthesis**

7-A. Serine is decarboxylated to **ethanolamine** by a pyridoxal phosphate dependent decarboxylase (Fig. 15.10). Ethanolamine is further utilised for choline synthesis. Figure 15.12 shows the addition of 3 methyl groups to ethanol amine to form choline.

7-B. Choline is used for **acetyl choline** synthesis, which is an important neurotransmitter.

7-C. From choline, 3 one-carbon groups (–CH3) can be removed. So, choline is an important **one-carbon donor** (Fig. 15.12)

---

8-A. Serine contributes the nitrogenous base in amino phospholipids.

8-B. **Sphingosine** the alcohol present in sphingolipids is synthesized from serine and palmitoyl CoA.
9. Serine as a Component of Protein
   i. In phosphoproteins, serine serves to esterify phosphate groups, e.g. casein.
   ii. Glycogen phosphorylase is activated by phosphorylation, while pyruvate kinase and phospho fructo kinase-2 are activated by dephosphorylation. This covalent modification serves as a mechanism of regulation of enzyme activity.
   iii. In glycoproteins, the carbohydrate groups are usually attached to the hydroxyl groups of serine or threonine residues of the protein. Serine forms the active group of many enzymes (serine proteases), e.g. trypsin and coagulation factors.

   An overview of serine metabolism is given in Figure 15.13.

Selenocysteine (SeCys) (21st amino acid)
Selenocysteine is abbreviated as SeCys. It is seen at the active site of the following enzymes: a) Thioredoxin reductase; b) Glutathione peroxidase, which scavenges peroxides; c) 5'-De-iodinase that removes iodine from thyroxine to make tri-iodo-thyronine and d) Selenoprotein P, a glycoprotein seen in mammalian blood. Replacement of SeCys by Cys will lead to decreased activity of these enzymes. Deficiency of some of these enzymes with anti-oxidant function may be related with atherosclerosis. Concentration falls in selenium deficiency.

   Its structure is COOH–CHNH2–CH2–SeH. It is directly incorporated into proteins during translation process. Biosynthesis of selenocysteine is by replacing the oxygen of serine by selenium; this is done by two steps:

   \[ \text{Se + ATP} \rightarrow \text{Se-P + AMP + Pi} \]
   \[ \text{Serine + Se-P} \rightarrow \text{SeCys + Pi} \]

   Its genetic code is UGA. The tRNA-Sec is the specific tRNA, inserting SeCys. However, normally UGA codon is a stop signal. UGA code for SeCys is identified by a SeCys insertion element in the mRNA, with the help of a specific elongation factor. The tRNA-Sec is first charged with serine, then it is converted into SeCys. This is then inserted into the correct position, when protein is synthesized.

ALANINE (Ala) (A)
Alanine is a non-essential glucogenic amino acid. Alanine can be formed by transamination of pyruvate. The enzyme is alanine amino transferase (ALT) (Fig 3.18).

   \[ \text{Pyruvate + Glutamate} \rightarrow \text{Alanine + alpha ketoglutarate} \]

   This reaction requires pyridoxal phosphate (PLP). ALT level in blood is increased in liver diseases; this clinical significance is indicated in Chapter 23. Under conditions of starvation, the glucose alanine cycle is of special metabolic significance (Fig. 9.30). Alanine is quantitatively the most important amino acid taken up by the liver from peripheral tissues, particularly from skeletal muscle. It forms a major participant in inter-organ transport of nitrogen (Figs 14.4 and 14.5).
namely, D-threonine, L-threonine, L-allothreonine and D-allothreonine. Threonine does not directly undergo transamination, but undergoes deamination forming alpha keto butyric acid (reaction similar to serine, Fig. 15.9). The enzyme is threonine dehydratase. In turn, alpha keto butyric acid can be oxidatively decarboxylated to propionyl CoA, then converted to succinyl CoA, which enters the gluconeogenesis pathway.

Threonine may be cleaved by threonine aldolase to give rise to glycine plus acetaldehyde. The latter is acted upon by aldehyde dehydrogenase to form acetate, which is activated to acetyl CoA by thiokinase.

The OH group of threonine residue in protein serves to provide a site for phosphorylation (as in the case of serine). This OH group also serves for combining carbohydrate residues to proteins, so as to make glycoproteins.

**Methionine (Met) (M)**

It is sulfur containing, essential, glucogenic amino acid. Degradation of methionine results in the synthesis of cysteine. The sparing action of cysteine on methionine is thus explained.

Metabolism of sulfur containing amino acids may be studied under the following major headings:

A. Activation of methionine and transmethylations
B. Conversion of methionine to cysteine
C. Degradation of cysteine

1. **Activation of methionine to SAM:** In the major pathway, methionine is activated to 'active methionine' or S-adenosyl methionine (SAM). The adenosyl group is transferred to the sulfur atom. (Step 1, Fig. 15.14). This is done by the enzyme, **methionine adenosyl transferase** (MAT). There are 3 isoenzymes for MAT, out of which 1 and 3 are of hepatic origin. SAM is the main source of methyl groups in the body.

2. **Methyl transfer.** In methionine, the thio-ether linkage (C–S–C) is very stable. In SAM, due to the presence of a high energy bond, the methyl group is labile, and may be transferred easily to other acceptors (Step 2, Fig. 15.14; and Table 15.1).

3. **Homocysteine.** From the S-adenosyl homocysteine (SAH), the adenosyl group is removed to form homocysteine, which is the higher homologue of cysteine (Step 3, Fig. 15.14).

4. **Methionine synthesis.** Homocysteine can be converted to methionine by addition of a methyl group. This methyl group is donated from one-carbon pool with the help of vitamin B12 (Step 4, Fig. 15.14).

5. **Homocysteine degradation:** Homocysteine condenses with serine to form cystathionine. This is catalysed by pyridoxal phosphate dependent cystathionine-beta synthase (No.5, Fig. 15.15). Absence of this enzyme leads to homocystinuria.

6. **Cysteine synthesis:** In the next step cystathionine is hydrolysed by cystathionase to form cysteine and homoserine (No.6, Fig. 15.15). Net result is that the SH group from methionine is transferred to serine to form cysteine. This is called trans-sulfuration reaction.
Chapter 15; Simple, Hydroxy and Sulfur Containing Amino Acids

1. Creatine (Fig. 15.5)
2. Epinephrine (Fig. 17.4)
3. Choline (Fig. 15.12)
4. Melatonin (Fig. 17.10)

These reactions are called methyl transfer reactions, and these are carried out with the help of S-adenosyl methionine (SAM) (Step 2, Fig. 15.15). Methyl groups are originally derived from the one carbon pool (Details in Chapter 14). The methyl-THFA can transfer the methyl group to homo-cysteine (Step 4, Fig. 15.15). Vitamin B₁₂ is the co-enzyme for the reaction. This would account for the deficiency of folic acid associated with B₁₂ deficiency (folate trap). SAM is the methyl donor for all the transmethylation reactions.

A summary of methionine metabolism is shown in Fig.15.16. The roles played by vitamins are also shown in that figure.

**Cysteine (Cys)(C)**

It is non-essential and glucogenic. Cysteine is present in large quantity in keratin of hair and nails. Formation of Cysteine is by using the carbon skeleton contributed by serine and sulfur originating from methionine. Methionine → SAM → SAH → Homocysteine → Cystathionine → Cysteine (Figs 15.15 and 15.16). See Trans-sulfuration, item No.6, under methionine degradation.

1. Creatine (Fig. 15.5)
2. Epinephrine (Fig. 17.4)
3. Choline (Fig. 15.12)
4. Melatonin (Fig. 17.10)

These reactions are called methyl transfer reactions, and these are carried out with the help of S-adenosyl methionine (SAM) (Step 2, Fig. 15.15). Methyl groups are originally derived from the one carbon pool (Details in Chapter 14). The methyl-THFA can transfer the methyl group to homo-cysteine (Step 4, Fig. 15.15). Vitamin B₁₂ is the co-enzyme for the reaction. This would account for the deficiency of folic acid associated with B₁₂ deficiency (folate trap). SAM is the methyl donor for all the transmethylation reactions.

A summary of methionine metabolism is shown in Fig.15.16. The roles played by vitamins are also shown in that figure.
Degradation of Cysteine

1. Transamination: Cysteine is transaminated to form beta mercapto pyruvic acid and finally pyruvate (Fig. 15.17). The beta mercapto pyruvate can transfer the S to CN to form thiocyanate (SCN).

2. The sulfur may be removed either as \( \text{H}_2\text{S} \) or elemental sulfur or as sulfite.

3. Cysteine on decarboxylation gives beta mercapto ethanolamine (Fig. 15.18). This is used for synthesis of co-enzyme A (Chapter 34).

Metabolic Functions of Cysteine

1. Formation of Glutathione

Glutathione is gamma glutamyl cysteinyl glycine (Fig. 15.19). Glutathione is generally abbreviated as GSH, to indicate the reactive SH group. It was isolated in 1921 by Sir Frederick Hopkins (Nobel prize, 1929).

Glutamate + Cysteine → gamma glutamyl cysteine

Glutamyl cysteine + glycine → glutathione

Both steps need hydrolysis of one ATP each.

2. Amino Acid Transport

The role of glutathione in the absorption of amino acid is shown in Figure 14.3.

3. Co-enzyme Role

Metabolic role of GSH is mainly in reduction reactions

\[
2\text{GSH} \rightarrow \text{GS-SG} + \text{H}_2
\]

The hydrogen released is used for reducing other substrates. A few examples are shown below:

i. Maleyl acetoacetate → fumaryl acetoacetate

ii. Cysteic acid → taurine (Fig. 15.22)

iii. (Iodine) I\(_2\) + 2GSH → 2HI + GS-SG

4. RBC Membrane Integrity

Glutathione is present in the RBCs. This is used for inactivation of free radicals formed inside RBC. The enzyme is glutathione peroxidase, a selenium containing enzyme (GPx in Fig. 15.21). The glutathione is regenerated by an NADPH dependent glutathione reductase (GR in Fig. 15.21). The NADPH is derived from the glucose-6-phosphate (GPD) shunt pathway. The occurrence of hemolysis in GPD deficiency is attributed to the decreased regeneration of reduced glutathione (Chapter 23).

**Fig. 15.20. Detoxification by glutathione; 1 = Glutathione- S-transferase (GST); 2 = peptidase; 3 = acetylase**

**Fig. 15.21. Free radical scavenging**
10. N-Acetyl cysteine (NAC) is believed to improve the body levels of glutathione. Hence it is used as an adjuvant in the treatment of injury by free radicals. Glutathione and NAC have therapeutic effects in chronic hepatitis B patients.

11. In erythrocytes, the rate of GSH synthesis is determined by the availability of L-cysteine. There is a significant decline in the influx of L-cysteine in erythrocytes during aging in humans. Cysteine supplementation has been shown to ameliorate several parameters that are known to degenerate during human aging; this has led to an interesting hypothesis that aging could be a cysteine deficiency syndrome.

A summary of the methionine and cysteine metabolism is shown in Box 15.1.

### Metabolism of Sulfur

The sulfur present in body may be either organic sulfur as a component of proteins (sulfur containing amino acids) or as part of sulfatides and glycosaminoglycans (GAG). Inorganic sulfur is derived from the sulfur containing amino acids by trans-sulfuration or desulfuration reactions. The \( \text{H}_2\text{S} \) derived from cysteine may be oxidized to sulfites and thiosulfates and further oxidized to sulfate. The excretory forms of sulfur in urine are:

- a. inorganic sulfates,
- b. organic or ethereal sulfates, and
- c. neutral sulfur.

### Formation of Taurine

Cysteine is oxidized to cysteic acid (step 1, Fig. 15.22) and then decarboxylated to form taurine (step 2). Alternatively cysteine is oxidized to cysteine sulfinic acid. It is then decarboxylated by a decarboxylase to hypotaurine which in turn is oxidised to taurine. Taurine is used for conjugation of bile acids.

\[
\text{Taurine} + \text{Cholyl CoA} \rightarrow \text{Taurocholate} + \text{CoA-SH}
\]

Taurine is a modulator of calcium fluxes, calcium binding and movement. In the CNS it is an inhibitory neurotransmitter.

### Keeping the correct structure of proteins

Cysteine residues in polypeptide chains form disulfide bridges to make active proteins, e.g. insulin (Chapter 4) and immunoglobulins (Chapter 49). Protein disulfide isomerase forms these disulfide bonds.

---

**Fig. 15.22. Formation of taurine from cysteine**

**Fig. 15.23. Phosphoadenosine phosphosulfate (PAPS)**
Formation of Active Sulfate
Active sulfate or Phosphoadenosine phospho-5'-sulfate (PAPS) is formed by the reaction between ATP and SO$_4$ and the sulfate is attached to the ribose-5'-phosphate (Fig. 15.23). PAPS is used for various sulfuration reactions, e.g. synthesis of sulfatides, glycosaminoglycans, etc.

Cystinuria
Cystinuria is one of the inborn errors of metabolism included in the Garrod's tetrad. It is an autosomal recessive condition. The disorder is attributed to the deficiency in transport of amino acids (Table 15.2). Signs and symptoms include:

i. Abnormal excretion of cystine and to a lesser extent lysine, ornithine and arginine. Hence the condition is also called Cystine-lysinuria.

ii. Crystalluria. In acidic pH, cystine crystals are formed in urine.

iii. The crystals form calculi (stones).

iv. Obstructive uropathy which may lead to renal insufficiency.

v. Treatment is to increase urinary volume by increasing fluid intake. Solubility of cystine is increased by alkalinization of urine by giving sodium bicarbonate.

Cyanide-nitroprusside test
It is a screening test. 5 ml urine saturated with sodium chloride, 4 drops of ammoniacal silver nitrate. After 1 min, KCN (potassium cyanide) is added drop by drop until solution is clear. Then 4 drops of freshly prepared sodium nitroprusside is added. A magenta-red colour appearing within 2-3 min and persisting for at least 2-3 min is indicative of the presence of homocystine/homocysteine in urine. Specific amino aciduria may be confirmed by chromatography.

Cystinosis
It is a familial disorder characterized by the widespread deposition of cystine crystals in the lysosomes. Cystine accumulates in liver, spleen, bone marrow, WBC, kidneys, cornea and lymph nodes (Table 15.2). There is an abnormality in transport of cysteine which is responsible for the accumulation. It is an autosomal recessive condition. Microscopy of blood shows cystine crystals in WBCs. Treatment policies are to give adequate fluid intake so as to increase urine output, alkalinization of urine by sodium bicarbonate, as well as administration of D-penicillamine.

Hypermethioninemias
Causes of hypermethioninemia are:
1. impaired utilization
2. excessive remethylation of homocysteine,
3. secondary to hepatic dysfunction.

Oasthouse syndrome is due to malabsorption of methionine. Such children excrete methionine, aromatic amino acids and branched chain amino acids in urine.

HOMOCYSTINURIAS
First described only in 1962, these are the latest in the series of inborn errors of metabolism. All of them are autosomal recessive conditions. Incidence is 1 in 200,000 births.

Box 15.1. Summary of Met/Cys Metabolism

Box 15.2. Homocysteine and Heart Attacks
An increase of 5 micromol / L of homocysteine in serum elevates the risk of coronary artery disease by as much as cholesterol increase of 20 mg/dl. Homocysteine interacts with lysyl residues of collagen interfering with collagen cross linking. It forms homocysteine thiolactone, a highly reactive free radical which thiolates LDL particles. These particles tend to aggregate, are endocytosed by macrophages and increase the tendency for atherogenesis.

Providing adequate quantity of pyridoxine, vitamin B$_6$ and folic acid will keep homocysteine in blood in normal levels.

Maternal hyperhomocysteinemia is known to increase the chances of neural tube defects in foetus. So, high doses of folic acid are advised in pregnancy.
Normal homocysteine level in blood is 5-15 micromol/L. In diseases, it may be increased to 50 to 100 times. Moderate increase is seen in aged persons, vitamin B$_12$ or B$_6$ deficiency, tobacco smokers, alcoholics and in hypothyroidism. Substantial increase is noticed in congenital enzyme deficiencies.

Large amounts of homocystine are excreted in urine. In plasma, homocysteine (with -SH group) and homocystine (disulfide, -S-S- group) exist. Both of them are absent in normal urine; but if present, it will be the homocystine (disulfide) form.

If homocysteine level in blood is increased, there is increased risk for coronary artery diseases. Clinical importance is shown in Box 15.2. The following are the causes of congenital homocystinurias:

1. **Cystathionine Beta Synthase Deficiency**
   i. It causes elevated plasma levels of methionine and homocysteine. There is increased excretion of methionine and homocystine in urine. Plasma cysteine is markedly reduced.

2. **Cobalamin Deficiency**
   The enzyme, N$^5$-methyl-THFA-homocysteine-methyltransferase is dependent on vitamin B$_{12}$. Therefore, vitamin B$_{12}$ deficiency may produce alteration in methionine metabolism. Blood contains increased level of homocysteine, but methionine level is low. Urine contains homocystine.

3. **Deficient N$^5$, N$^{10}$-Methylene THFA Reductase**
   This enzyme catalyses the reaction N$^5$, N$^{10}$-methylene-THFA to N$^5$-methyl-THFA (Fig.14.16). Deficiency of this enzyme leads to reduced methionine synthesis with consequent increase in homocystine level in urine. Behavioral changes and vascular abnormalities may be observed. Folate supplementation is beneficial.

4. **Cystathioninuria**
   It is due to cystathionase deficiency. It is an autosomal recessive condition. Mental retardation, anemia, thrombocytopenia, and endocrinopathies accompany this condition. Less severe forms may be seen in conditions interfering with homocysteine remethylation, in B$_{12}$ deficiency and in impaired folate metabolism. Acquired Cystathioninuria may be due to pyridoxine deficiency. It may also be seen in liver diseases and after thyroxine administration. Diagnosis is based on cyanide-nitroprusside test (negative) and detection of cystathionine in urine. Large quantities of pyridoxine (200-400 mg) may be beneficial.

5. **Acquired hyperhomocysteinemias**
   a. Nutritional deficiency of vitamins, such as cobalamin, folic acid and pyridoxine.
   b. Metabolic: Chronic renal diseases, hypothyroidism.
   c. Drug induced: Folate antagonists, vitamin B$_{12}$ antagonists; pyridoxine antagonists; estrogen antagonists, nitric oxide antagonists.

   Table 15.2 shows the salient features of these amino acidurias.
Acidic, Basic and Branched Chain Amino Acids

(Glutamic Acid, Aspartic Acid, Lysine, Arginine, Nitric Oxide, Histidine, Valine, Leucine, Isoleucine)

CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:
1. Glutamic acid, Glutamine
2. Aspartic acid, Asparagine
3. Lysine
4. Arginine, Nitric oxide
5. Ornithine, Polyamines
6. Valine, Leucine, Isoleucine
7. Histidine, Histamine

GLUTAMIC ACID (Glu) (E)

Glutamic acid was isolated by Ritthausen in 1866. It plays a central role in the metabolism of amino acids. It is generated during transamination reactions.

1. **Transamination reactions**: Most amino acids transfer their amino group to alpha keto glutaric acid to form glutamic acid (Fig. 14.8).

   aminotransferase

   Amino acid + Alpha keto acid

   Alpha keto glutarate + Glutamic acid

2. Glutamic acid is also formed during the metabolism of histidine, proline and arginine.

3. **Oxidative deamination**: Glutamic acid is deaminated to form alpha keto glutarate by the enzyme glutamate dehydrogenase with the help of NAD⁺ (Fig. 14.9).

   Glutamic acid -----> Alpha keto glutarate + NH₃

With the help of NADPH, this reaction is reversible, so that glutamic acid can be synthesized.

4. **Glucogenic**: Glutamic acid enters the TCA cycle, becomes oxaloacetate and goes to glucogenic pathway.

5. **N-acetyl glutamate** (NAG) is a positive modifier of carbamoyl phosphate synthetase-I in the mitochondria.

   Glutamic acid + Acetyl CoA → NAG + CoASH

6. **Glutamine**: (See below)

7. **Gamma carboxy glutamic acid** (GCGA) is present in prothrombin. The gamma carboxyl group is added as a post translational modification, which needs vitamin K (Chapter 33).

8. **Excitatory neurotransmitter**: Neurons contain NMDA (N-methyl-D-aspartate) receptor, named after a drug that selectively binds to it. Stimulation of NMDA receptors by glutamate opens calcium channel, leading to stimulation of NOS (nitric oxide synthase). This results in transient production of NO (nitric oxide). NO binds with high affinity to the guanyl cyclase; the active guanyl cyclase raises the cellular level of cyclic GMP in neighboring neurons. Thus, neurons are excited.

9. **Glutathione**: Glutamate is a constituent of the tripeptide glutathione (Fig. 15.19). It is used by bacteria for folic acid synthesis. Glutamic acid metabolism is summarized in Fig. 16.4.

10. **Glutamic acid is decarboxylated to GABA**.

**Gamma Amino Butyric Acid (GABA)**

A. **Metabolism**: Glutamic acid on decarboxylation gives rise to gamma amino butyric acid (GABA). (Step 1, Fig. 16.2). Part of the glutamate in the brain can be shunted through the GABA pathway and catabolized to succinate (Steps 2 and 3, Fig. 16.2).

B. **GABA is an inhibitory neurotransmitter** and it opens the chloride channels in post-synaptic membranes in CNS.
Chapter 16; Acidic, Basic and Branched Chain Amino Acids

C. Pyridoxal phosphate: Both the formation and catabolism of GABA require pyridoxal phosphate as co-enzyme (Steps 1 and 2, Fig. 16.2). Therefore in pyridoxine deficiency the metabolism of glutamate by the GABA shunt pathway is affected.

D. Since GABA is an inhibitory transmitter, a low level of GABA or deficiency of pyridoxal phosphate would lead to convulsions. Sodium valproate which inhibits GABA oxidase is used in the treatment of epilepsy.

E. Congenital deficiencies of GABA amino transferase and succinic semialdehyde dehydrogenase (leading to hydroxy butyric aciduria) are reported, but are very rare.

GLUTAMINE (Gln) (Q)
Glutamine was isolated as free amino acid from beetroot by Schulze and Bosshard in 1833. Glutamine was identified as a component of all proteins by Charles Chibnall and Manayath Damodaran in 1932.

1. It is a glucogenic amino acid. It is synthesized from glutamic acid (Fig. 16.1).
2. The amidation of glutamic acid to glutamine is catalyzed by glutamine synthetase. Glutamic acid can react with a molecule of NH₃ in presence of ATP (Fig. 16.1). This reaction is important in ammonia trapping in brain as well as for transport of ammonia in a nontoxic form (Chapter 14).
3. Glutamine is hydrolyzed to glutamate and NH₃ by the enzyme glutaminase. This reaction is seen in the renal tubular cells. This ammonia reacts with H⁺ to buffer acids excreted in urine (see Chapter 29).
4. Major fate of glutamine is to be hydrolyzed to glutamate and NH₃ (Fig. 16.1). Glutamic acid is then deaminated to alpha ketoglutarate and enters TCA cycle for further catabolism.
5. The N atoms 3 and 9 of purines are derived from glutamine (Chapter 39).
6. Glutamine is the source of 3rd N of pyrimidine.
7. Glutamine is the source of NH₂ group of guanine and cytosine (Chapter 39).
8. Glutamine is a conjugating agent. For example, production of phenyl acetyl glutamine (see phenylketonuria, Chapter 17). Glutamine metabolism is summarized in Fig. 16.4.
9. Glutamine donates the amino group of amino sugars and amide group of nicotinamide.

ASPARTIC ACID (ASP) (D)
1. It was isolated by Kreusler in 1869. It is a non-essential, glucogenic amino acid.
2. Aspartate, on transamination gives rise to oxaloacetate which initiates the TCA cycle. Aspartate amino transferase (AST) transfers the amino group of aspartate to alpha ketoglutarate to form oxaloacetate.

\[
\text{(AST) (PLP)} \quad \text{Aspartate} + \text{Alpha Ketoglutarate} \rightarrow \text{Oxaloacetate}
\]

3. The clinical significance of AST is described in Chapter 6. AST is increased in hepatic diseases and cardiac ischemia.
4. Malate aspartate shuttle transfers the cytoplasmic NADH into mitochondria for oxidation in the electron transport chain. It is

[Fig. 16.2. GABA metabolism]

[Fig. 16.3. Asparagine synthesis and breakdown. 1 = asparagine synthetase; 2 = asparaginase. Compare these reactions with those of Figure 16.1]
Fig. 16.4. Summary metabolisms of aspartic acid, asparagine, glutamic acid and glutamine

also used for transport of oxaloacetate into cytoplasm (see Fig.19.5).

5. Aspartic acid is an important member of \textit{urea cycle} (Fig.14.12). It directly contributes its \textit{alpha amino group} to the urea molecule.

6. The carbon skeleton of aspartate can also enter the glucogenic pathway as fumarate.

\[ \text{Citrulline} + \text{Aspartate} \rightarrow \text{Arginine} + \text{Fumarate} \]

7. Aspartate is used for the synthesis of \textit{purines} (1st nitrogen and 6th NH\textsubscript{2} group) (Fig. 39.10).

8. The whole molecule of aspartate is incorporated into the \textit{pyrimidine ring} (1st nitrogen and carbons 4,5,6) (Fig. 39.17). Aspartic acid metabolism is summarized in Figure 16.4.

\textbf{ASPARAGINE (Asn) \textsubscript{(N)}}

It is so named because it is originally isolated from asparagus. Vauquelin and Robiquet in 1906 isolated asparagine. It was shown to be a component of all proteins by Manayath Damodaran in 1932. Aspartate reacts with ammonia to form asparagine (Fig. 16.3). This is a reaction similar to formation of glutamine. But glutamine (and not ammonium ion) provides the nitrogen atom. Asparagine can be hydrolyzed to aspartate and NH\textsubscript{3} by asparaginase. \textbf{L-asparaginase} is an anticancer drug against leukemias and lymphomas, because those cells cannot synthesize asparagine; the enzyme will destroy the available asparagine in the blood; so the cancer cells will die. Asparagine is a \textit{glucogenic} amino acid (Fig. 16.4).

\textbf{Dicarboxylic Amino Aciduria}

A few cases have been reported. The manifestations may vary; some having mental retardation and hypoglycemia, while others were asymptomatic. The defect is therefore attributed to the defect in the renal tubular reabsorption of glutamate and aspartate.

\textbf{BASIC AMINO ACIDS}

Basic amino acids are Arginine, Lysine and Histidine. Out of this, Arginine and Lysine are diamino monocarboxylic acids, and are strongly alkaline in nature. Histidine is mildly alkaline.

\textbf{LYSINE (Lys) \textsubscript{(K)}}

Drechsel in 1889 isolated lysine; Hopkins in 1907 showed its essentiality for growth; Schryver and Buston in 1925 identified hydroxyllysine. Lysine is an \textit{essential} basic amino acid. It is \textit{deficient in cereals}. It does not undergo transamination. Lysine is predominantly \textit{ketogenic}. Alpha keto glutarate combines with lysine to form \textit{Saccharopine}, from which glutamate is removed. This catabolic pathway further proceeds through the intermediates of amino adipic acid, alpha keto adipic acid, glutaryl CoA, crotonyl CoA and finally into the pathway of odd numbered fatty acids. \textbf{Hyperlysinemia}s result from congenital deficiency of any of the enzymes of the above pathway. Mental retardation and cortical degeneration are seen in these conditions. Lysine serves the following functions.

\textit{a.} Lysine and \textit{hydroxy lysine} residues of collagen and elastin are important in cross linking (Chapter 52).
Chapter 16; Acidic, Basic and Branched Chain Amino Acids  ■  197

Fig. 16.5. Metabolism of arginine and ornithine

Hydroxyl group is usually attached to the delta carbon atom of lysine.

b. The epsilon amino group of lysine can form Schiff bases, thus linking to proteins, e.g. Pyridoxal phosphate with transaminases.

c. Negative charge of epsilon amino group of lysine forms salt bridges with oppositely charged groups. This is important in maintenance of quaternary structure of proteins, e.g. Hb.

d. Lysine is found in large quantities in histones, the basic protein associated with nucleic acids.

e. Lysine is the precursor of carnitine. Synthesis of carnitine from protein bound lysine may be outlined as follows: Protein bound lysine + 3SAM → 3SAH + Protein bound Trimethyl lysine → Free Trimethyl lysine → (hydroxylase) → Hydroxy trimethyl lysine → (aldolase) → glycine + gamma butyryl betaine → (hydroxylase) → Carnitine.

f. Bacterial putrefication (decarboxylation) of lysine in the intestine gives rise to cadaverine.

ARGinine (Arg) (R)

2. It is a highly basic, semi-essential amino acid. Arginine is glucogenic. The catabolic pathway of arginine is shown in Figure 16.5.

3. In the urea cycle, arginine splits into urea and ornithine (Fig.14.12). Ornithine is then transaminated to glutamate semialdehyde and then to glutamate.

4. Congenital deficiency of ornithine amino transferase causes elevated plasma and urinary ornithine; this leads to atrophy of the retina.

5. Congenital deficiency of mitochondrial ornithine-citrulline antiporter leads to hyperornithinemia-hyperammonemia syndrome.

6. Arginine reacts with glycine to form guanoacetic acid which is methylated to creatine (Fig. 16.5).

7. Arginine is the precursor of nitric oxide which is an important signal molecule in the body.

NITRIC OXIDE (NO)

It is a toxic pollutant of air and automobile exhausts. But now it is shown to possess more potential biological functions than any other known molecule. In 1977, Ferid Murad showed that the vasodilatory effect of nitroglycerine is due to the release of NO. In 1980, Robert Furchgott showed that “endothelium derived relaxing factor” (EDRF) is required for arterial dilatation. In 1987, Louis Ignarro showed that EDRF is chemically NO. They were awarded Nobel Prize in 1998.

Chemistry

Nitric oxide is an uncharged molecule having an unpaired electron, so it is a highly reactive “free radical”. So it is correctly written with a superscript dot (NO') (Chapter 20). Half life is very short, only about 0.1 second.

Synthesis of Nitric Oxide

Nitric oxide is formed from arginine by the enzyme nitric oxide synthase (NOS). It contains heme, FAD, FMN and tetrahydrobiopterine. NOS catalyzes five-electron oxidation of the nitrogen of arginine. Calmodulin is required to modulate its activity. The guanidino nitrogen of arginine is incorporated into NO'. From the molecular oxygen, one atom is added to NO' and the other into citrulline. Therefore, the enzyme is a di-oxygenase (Fig. 16.6).

Metabolic Fate

Nitric oxide has a very short half life (3-4 seconds). NO combines with oxygen to form NO2. These nitrates are excreted through urine. Reacting with hemoglobin, NO is converted to NO3; and nitrates are also excreted in urine. Very low quantity of NO is expelled through lung. On exposure to superoxide anion (O2-), nitric oxide (NO') is converted to a highly reactive free radical, peroxynitrite (OONO'), which causes lipid peroxidation, cell injury and cell death.

Fig.16.6. Nitric oxide synthase (NOS) reaction. The enzyme contains heme, FAD, FMN and tetrahydrobiopterine. It utilizes NADPH
Iso-enzymes of NOS
There are 3 isoforms of NOS, these are products of 3 different genes. All forms are seen in almost all tissues.

Neuronal NOS: NOS1 or nNOS or neuronal NOS is seen in central and peripheral neurons. Nitrogenic neurons are seen especially in cerebellum and gastrointestinal tract. It is mainly a cytoplasmic enzyme. It is activated by calcium. The gene for neuronal NOS is seen on chromosome 12. NOS1 is implicated in the long QT interval syndrome.

Macrophage NOS: NOS-2 or iNOS or inducible NOS or macrophage NOS is mainly seen in macrophages and neutrophils; but is also present in hepatocytes. It is induced by cytokines (interleukin-1 and tumor necrosis factor) and during inflammation. It is a cytoplasmic enzyme. Calcium does not activate this iso-enzyme. Gene for iNOS is on chromosome 17.

Endothelial NOS: NOS-3 or eNOS or endothelial NOS is seen in endothelial cells, platelets, endocardium and myocardium. In these sites, the NO is constantly produced and released, so that arterial relaxation occurs. It is localized in the plasma membrane. It is activated by calcium. The gene for endothelial NOS is on chromosome 7.

Mechanism of Action of Nitric Oxide
NOS is activated by acetyl choline. The ACh attaches with the receptor, and the signal is transmitted through inositol triphosphate, leading to release of calcium ions, which activates NOS. TNF alpha will increase the activity of the enzyme. Glutamate acts on N-methyl-D-aspartate (NMDA) receptors to cause a long-standing calcium influx. This activates NOSn. NO stimulates the releasing hormones (CRH, GHRH and LHRH).

Physiological Actions of Nitric Oxide
1. Blood vessels: NO is a potent vasodilator. The normal blood pressure is maintained by the NO liberated by endothelial NOS (NOSe). NO causes cerebral, coronary, renal and muscle arteries to dilate. A deficiency of NO is associated with hypertension. Excessive production of NO results in refractory hypotension, which may be seen in patients with septicemic shock.
2. Central nervous system: In CNS, NOSn isoform is present. Glutamate acts on N-methyl-D-aspartate (NMDA) receptors to cause a long-standing calcium influx. This activates NOSn. NO stimulates the releasing hormones (CRH, GHRH and LHRH).
3. Macrophages: Macrophages contain the isoform NOSi (i stands for inducible). This enzyme produces NO and peroxynitrite; which are lethal to micro-organisms. NO production in macrophage is induced by interleukin and tumor necrosis factor.
4. Platelets: NO inhibits adhesion of platelets and so depresses platelet functions.
5. Intestinal system: NO is a non-adrenergic and non-cholinergic (NANC) neurotransmitter, especially in gastrointestinal tract and urogenital tract. It relaxes smooth muscles and leads to reduced gastrointestinal motility and relaxation of sphincters. A deficiency of NO producing neurons with decreased motility is responsible for infantile hypertrophic pyloric stenosis and Hirschsprung’s disease.

Nitric Oxide in Diseases and Treatment
1. Angina Pectoris: Nitroprusside can directly release NO. Nitroglycerine (glyceryl trinitrite) requires glutathione to produce NO. These will dilate coronary arteries; and are beneficial in treating angina pectoris.
2. Pulmonary Hypertension: Inhalation of NO is useful in the treatment of pulmonary hypertension and high altitude pulmonary edema. NO produces pulmonary vasodilatation, without lowering systemic blood pressure.
3. Impotence: NO relaxes smooth muscles in the corpus cavernosum and increases blood flow into the penis and makes it erect. Sildenafil citrate (Viagra) selectively inhibits the specific phosphodiesterase type 5 (PDE-5); thus inhibiting hydrolysis of cGMP; and increasing the concentration of cGMP in corpus cavernosum.
4. Shock: Induction of NO from macrophages is increased in sepsis and is responsible for severe vasodilation and shock. This hypotension is refractory and not responding to vasoconstrictor drugs.
5. Enhancers of NO activity: S-nitroglutathione (GS-NO) is a NO donor which inhibits platelet agglutination. N-acetyl cysteine (NAC) is a glutathione precursor; it protects NO from being metabolized by free radical scavengers, and hence enhances NO activity.
6. Antagonists of Nitric Oxide: Development of specific inhibitors of different isoforms of NOS promises therapeutic uses. N-monomethyl arginine (NMMA) competitively inhibits NOS. ADMA (asymmetric dimethyl-arginine), an endogenous arginine analogue acts as an NOS inhibitor; ADMA is seen to be increased in hyper-homocysteinemia and pre-eclampsia. In eclampsia, the hypertension is due to the lowered production of NO.

POLYAMINES
Polyamines are putrescine, spermidine and spermine. They are aliphatic amines. Humans synthesize about 0.5 mmol of spermine per day. They are synthesized from Ornithine.
African sleeping sickness and Indian Kala-azar are produced by parasites, trypanosomes. In these parasites, the half-life of ODC is many hours. DFMO inhibits polyamine synthesis, so parasites cannot divide, and the immune system of the host can kill them. The half-life of ODC in man is only 5 minutes. So, enzyme molecules are constantly synthesized, and hence the drug will not affect human beings. DFMO is also useful against \textit{Pneumocystis carinii} parasite infection, which is common in AIDS.

Biochemical Functions of Polyamines
Polyamines are required for protein biosynthesis. The translation initiation factor eIF-4D contains one \textit{hypusine} residue, which is formed by addition of butylamine moiety from spermidine to lysine. IF-4D is the only known protein containing hypusine.

Several roles are suggested for polyamines, e.g. cell proliferation, stabilisation of ribosomes and DNA, synthesis of DNA and RNA, protection of DNA against depurination, etc. Polyamine concentration is increased in \textit{cancer} tissues. Polyamines are \textit{growth factors} in cell culture systems. Methyl thio adenosine (MTA) (step 3) has growth inhibitory activity.

Decarboxylation of lysine produces \textit{cadaverine}, which is also seen in mammalian tissues. It is also sometimes included in the list of polyamines.

Details of synthesis are given in Figure 16.7. Key enzyme of polyamine synthesis is \textbf{ornithine decarboxylase} (ODC) (step 4). It requires pyridoxal phosphate, and is induced by steroid hormones. ODC gene is on chromosome no. 2. The genes for the enzyme SAM decarboxylase (step 2) are on chromosomes 6 and X. This enzyme has \textbf{pyruvate} (not PLP) as the prosthetic group; it is the only mammalian enzyme, known to contain bound pyruvate.

DFMO (difluromethyl ornithine) is a powerful inhibitor of polyamine synthesis. It is an example of \textbf{suicide inhibition}
Biogenic Amines
They are generally synthesized by decarboxylation of amino acids. A list of biogenic amines are shown in Table 16.1. They are basic in nature. They have diverse biological functions, which are described in appropriate chapters.

BRANCHED CHAIN AMINO ACIDS (BCA)
Leucine was discovered from cheese by Proust in 1818. Ehrlich isolated isoleucine in 1903 and Emil Fischer isolated valine in 1906. Valine (Val) (V) is glucogenic; Leucine (Leu) (L) is ketogenic while Isoleucine (Ile) (I) is both ketogenic and glucogenic. All the three are essential amino acids. Leucine is the major ketogenic amino acid. These amino acids serve as an alternate source of fuel for the brain especially under conditions of starvation.

All the three amino acids undergo similar sequence of reactions. These are summarized in Table 16.2. In this pathway, the second enzyme is branched chain alpha keto acid dehydrogenase. It is a complex of decarboxylase, transacylase and dihydrolipoyl dehydrogenase. So, this resembles pyruvate dehydrogenase (Fig. 9.22).

Maple Syrup Urine Disease (MSUD)
1. It is also called branched chain ketonuria. The incidence is 1 per 1 lakh births. The name originates from the characteristic smell of urine (similar to burnt sugar or maple sugar) due to excretion of branched chain keto acids.

ii. The basic biochemical defect is deficient decarboxylation of branched chain keto acids (BKA) (reaction 2 in Table 16.2).

iii. Clinical findings: Disease starts in the first week of life. It is characterized by convulsions, severe mental retardation, vomiting, acidosis, coma and death within the first year of life.

iv. Laboratory findings: Urine contains branched chain keto acids, valine, leucine and isoleucine. Rothera’s test is positive, but unlike in cases of ketoacidosis, even boiled and cooled urine will give the test. Diagnosis depends on enzyme analysis in cells. Diagnosis should be done prior to 1 week after birth.

v. Treatment: Giving a diet low in branched chain amino acids. Mild variant is called intermittent branched chain ketonuria. This will respond to high doses of thiamine. This is because the decarboxylation of the BKA requires thiamine. Liver transplantation has been successfully tried in some cases of MSUD.
Isovaleric Aciduria
Here leucine catabolism is affected. Severe metabolic acidosis and neurological deficit are seen. It is often fatal in early childhood. The characteristic offensive odor of urine is the first sign of the abnormal excretion of this metabolite. Very high amounts of abnormal metabolites are excreted in urine. The defect lies in reaction No. 3 of Table 16.2.

Histidine has an imidazole ring. It is a semi-essential basic amino acid. Its pK value is 6.1; and hence in proteins, histidine is responsible for the maximum buffering action. The histidine residues present in proteins provide additional charge and polarity to the molecule. Histidine residues of albumin and hemoglobin play a significant role in buffering action. In addition, the iron of the heme moiety of hemoglobin is attached to globin through two specific histidine residues designated as the proximal and distal histidine residues.

Histidine is first non-oxidatively deaminated by histidase to form urocanic acid (step 1, Fig. 16.8). It is then hydrated to imidazolone propionic acid (step 2) and then hydrolyzed to formimino glutamic acid (FIGLU) (step 3, Fig. 16.8). Figlu is cleaved into N5-formimino-THFA and glutamic acid (step 4, Fig. 16.8). Glutamic acid is transaminated to alpha keto- glutarate which can be converted to glucose. So histidine is glucogenic. Histidine contributes to the one carbon pool.

When folic acid is deficient, FIGLU is excreted in urine. Histidine can undergo transamination with pyruvate to form imidazole pyruvate and alanine.

Histamine
Histamine is formed from histidine by decarboxylation, catalysed by histidine decarboxylase (step 1, Fig. 16.9). The effects of histamine are summarised in Table 16.3. Smooth muscle contraction, enhanced vascular permeability, increased acid secretion are the important actions. So histamine causes fall in blood pressure.

The major cells producing histamine are platelets, mast cells and basophils. Certain antigens such as penicillin will elicit IgE antibodies that are fixed on the mast cells. When the next dose of penicillin is injected, it reacts with the antibodies; and degranulation of mast cells takes place. Histamine and slow reacting substance (SRS) are released. This leads to peripheral vasodilatation, fall in blood pressure and anaphylaxis.

Antihistamines are drugs which block histamine receptors. They are used to control allergic and anaphylactic reactions. The stimulant effect of histamine on gastric acid secretion is by acting on H2 receptors. Hence H2 receptor
The clinical features include mental retardation and delayed speech development. A low histidine diet may have some effect.

**Urocanic Aciduria**

It is due to the deficiency of urocanase. Urocanic acid and histidine are excreted in urine. Clinical manifestations are minimal.

**Imidazole Amino Aciduria**

It has dominant type inheritance. The defect is in the transport mechanism in kidney tubules. Cerebromacular and retinal degeneration may cause blindness.

**Folic Acid Deficiency**

Folic acid is the co-enzyme for the conversion of FIGLU to glutamate (See Chapter 34, under folic acid). Block in this step leads to increased excretion of FIGLU in urine.

**FIGLU Excretion Test**

It is a sensitive indicator for folic acid deficiency. About 5 g of histidine is given three times at 4-hourly intervals. Urine is collected for 24 hours after the initial dose. Normally less than 30 mg of FIGLU is excreted per day; the value is increased in folate deficiency.

Histidinemia

It is an autosomal recessive disease. The deficiency of histidase leads to accumulation of histidine in blood and body fluids and increased excretion of imidazole pyruvic acid in urine.
Aromatic Amino Acids and Amino Acidurias
(Phenylalanine, Tyrosine, Tryptophan, Proline)

Phenylalanine was isolated by Schulze in 1879 and Tyrosine by Liebig in 1846. In 1913, Abderhalden showed the essentiality of phenylalanine.

Step 1: Phenylalanine to tyrosine
The reaction involves addition of a hydroxyl group to the aromatic ring, by phenylalanine hydroxylase (step 1, Fig.17.1). It needs NADPH, NADH and tetrahydrobiopterine as co-enzymes. As this is an irreversible reaction, tyrosine cannot replenish phenylalanine. Hence, phenylalanine is essential in food.

It is a mixed function oxidase (mono-oxygenase). One molecule of O₂ is needed in this reaction; out of which one atom is incorporated in the OH group and the other is reduced to water. This reaction also needs the electron carrier tetra-hydro-biopterin which is regenerated by the reduction of dihydro-biopterin by a reductase using NADPH (step 1-A, Fig.17.1).

TYROSINE (Tyr) (T)
Tyrosine is an aromatic amino acid. It is synthesized from phenylalanine, and so is a non-essential amino acid. The need for phenylalanine becomes minimal, if adequate tyrosine is supplied in the food. Tyrosine is partly glucogenic and partly ketogenic.

Catabolism of Tyrosine (and Phenylalanine)
Step 2: Transamination
Degradative pathway of phenylalanine and tyrosine are the same, since phenylalanine is converted to tyrosine and then metabolized. Tyrosine is transaminated to give para hydroxy phenyl pyruvic acid by tyrosine transaminase (step 2, Fig.17.2). It is pyridoxal phosphate dependent. It is induced by glucocorticoids.

Step 3: Production of homogentisic acid
The next step (No. 3, Fig.17.2) is catalyzed by para hydroxy phenyl pyruvate hydroxylase. It is a
phenyl acetic acid or homogentisic acid. Ascorbic acid is helpful in this reaction.

**Step 4: Cleavage of aromatic ring**

Homogentisic acid oxidase opens the ring (step 4, Fig.17.2). It is also a di-oxygenase with an iron atom at the active site. The product is 4-maleyl acetoacetate.

**Step 5: Isomerization**

It then undergoes cis to trans isomerisation to form fumaryl acetoacetate by an isomerase (step 5, Fig.17.2). The isomerase requires glutathione (GSH) as a cofactor.

**Step 6: Hydrolysis**

Fumaryl acetoacetate is then hydrolyzed to fumarate and acetoacetate by a hydrolase (step 6, Fig.17.2). This results in the production of a glucogenic product (fumarate) and a ketone body (acetoacetate). Hence phenyl alanine and tyrosine are partly glucogenic and partly ketogenic.

**Important Specialized Products from Tyrosine**

1. Melanin
2. Catecholamines (Epinephrine)
3. Thyroxine

1. **Synthesis of Melanin**

Melanin pigment gives the black color to the skin and hair (Greek word Melan means black). There is only one enzyme involved, which catalyzes the first two steps. The remaining reactions are non-enzymatic and occur spontaneously.

   i. **Formation of DOPA:** The first step is the hydroxylation of tyrosine by tyrosinase. It is a mono-oxygenase containing copper (step 1, Fig.17.3). Molecular O₂ is used for the reaction, of which one atom is incorporated in the product, to form dihydroxy phenyl alanine or DOPA (Box 17.1).

   ii. **Formation of DOPA quinone:** Tyrosinase again acts on DOPA to form dopaquinone (step 2, Fig.17.3).

   iii. **Formation of indolequinone:** It is converted to indolequinone through a series of reactions
Chapter 17; Aromatic Amino Acids and Amino Acidurias

Box 17.1. Tyrosinase and Tyrosine Hydroxylase

Both these enzymes will add hydroxyl group to tyrosine to produce dihydroxy phenyl alanine (DOPA).

Tyrosinase is present in melanoblasts. The enzyme produces DOPA, which is used for melanin synthesis. Whereas Tyrosine hydroxylase is present in adrenal medulla and the DOPA thus generated is used for epinephrine synthesis. Thus even in Tyrosinase-deficient person (albinism), epinephrine synthesis is normal.

Box 17.2. Clinical Applications of Melanin

i. Copper deficiency: Since tyrosinase is a copper containing enzyme, there may be disturbances in pigmentation during copper deficiency. Hair synthesized at the time of deficiency may be depigmented. If copper deficiency is intermittent, alternate black and white regions may be seen in the hair (flag-type of hair).

ii. Malignant melanoma: Melanoblasts, especially in junctional naevi, may multiply to give rise to malignant melanoma. Melanogen may be excreted through urine in such conditions.

iii. Leukoderma: When tyrosinase or melanin forming cells or both are absent from epidermis, leukoderma (white patches) results.
iv. Graying of hair is also due to the disappearance of melanocytes from the hair root.

v. Albinism: Albinism and leukoderma are different. In albinism, tyrosinase is absent in melanocytes all over the body. See below in this chapter.

Regulation of Color of Skin

Melanocytes in the deeper layers of epidermis synthesise melanin in granular form in melanosomes. The color of the skin depends upon the distribution of melanoblasts, the concentration of melanin and its state of oxidation. The extracellular granules are later dispersed under the influence of melanocyte stimulating hormone (MSH). Alpha MSH has 13 amino acids, which constitute the amino terminal part of ACTH. Therefore, MSH has weak ACTH activity and ACTH has weak MSH activity. Melanin is found in the pigment epithelium in the eye, which gives the characteristic color of the eye.

2. Synthesis of Catecholamines

Catecholamines are derived from tyrosine. They are so named because of the presence of catechol nucleus. They include epinephrine, nor-epinephrine and dopamine. They are produced by the adrenal medulla and sympathetic ganglia.

i. Tyrosine hydroxylase: Tyrosine is first hydroxylated to dihydroxy phenyl alanine (DOPA) by tyrosine hydroxylase (step 1, Fig. 17.4). It is different from tyrosinase involved in melanin synthesis which catalyzes a similar reaction (Fig. 17.3 and Box 17.1). The tyrosine hydroxylase requires tetrahydro biopterine and NADPH (similar to phenylalanine hydroxylase).

ii. DOPA-decarboxylase: DOPA is decarboxylated to form Dopamine by DOPA-decarboxylase, a pyridoxal phosphate dependent enzyme (step 2, Fig. 17.4). It is a catecholamine.

Dopamine is an inhibitor of prolactin secretion. It is also an important neurotransmitter especially in extrapyramidal tract, substantia nigra and striatal tract.

Fig. 17.3. Melanin synthesis pathway; 1 and 2 steps have the same enzyme, tyrosinase

[Image of the melanin synthesis pathway diagram]
iii. Nor epinephrine: Dopamine is further hydroxylated to nor-epinephrine or nor-adrenaline (step 3, Fig.17.4). The term "nor" denotes that the molecule does not contain the "R" or methyl group.

iv. Epinephrine: In the next step, nor-epinephrine is methylated by the enzyme N-methyl transferase (NMT) to epinephrine or adrenaline (step 4, Fig.17.4). S-adenosyl methionine (SAM) is the methyl donor. It is mainly produced by adrenal medulla and adrenergic nerve endings. It is stored in chromaffin granules and released into blood. Epinephrine and Adrenaline are the two names for the same hormone (see Box 17.3).

Actions of Epinephrine
i. Epinephrine and nor-epinephrine increase the blood pressure.

   ii. Adrenaline also increases the rate and force of myocardial contraction.

iii. Epinephrine causes relaxation of smooth muscles of bronchi.

   iv. Adrenaline is anti-insulin in nature, it increases glycogenolysis and stimulates lipolysis.

   v. Adrenaline is released from adrenal medulla in response to flight, fight, fright, exercise and hypoglycemia.

---

**Box 17.3. Two Names**

Epinephrine and adrenaline are two names for the same hormone. John Jacob Abel discovered “epinephrine” in 1901. In the same year, Japanese-born chemist Jokichi Takamine, working independently, isolated the same hormone, which he called “adrenalin.” It was first marketed as Adrenaline for therapeutic use. Hence the word adrenaline is more used in clinical practice, while the term epinephrine is more favored in academic circles.

---

**Fig. 17.4. Metabolism of catecholamines**

In Parkinsonism, the dopamine content in brain is reduced. As dopamine will not enter into the brain cells, the precursor, L-Dopa is used as a drug in Parkinsonism.

Alpha methyl dopa will inhibit dopa decarboxylase and prevent production of epinephrine; so it is an antihypertensive drug.

Arvid Carlsson established dopamine as a neurotransmitter and developed L-dopa as a drug for the treatment of Parkinson's disease. Paul Greengard demonstrated that Dopamine-AMP-Regulated-Phospho-protein (DARPP32) is necessary for the phosphorylation cascade, leading to neuronal excitability. Eric Kandel showed that the DARPP32 dependent phosphorylation is the basis of short term and long term memory. All the three scientists were awarded Nobel Prize in 2000. Nor-epinephrine was identified as a neuro-transmitter in 1946 by Ulf von Euler, who was awarded Nobel prize in 1970.
2-A. Degradation of Adrenaline

i. The half-life of epinephrine is very short, only 2–5 minutes. Epinephrine is catabolized in tissues, by catechol-O-methyl transferase (COMT) (step 5, Fig. 17.4) to metanephrine.

ii. It is then acted upon by mono amine oxidase (MAO) (step 6). MAO will oxidatively deaminate compounds having the amino group attached to the terminal carbon atom. The major end product is 3-hydroxy-4-methoxy mandelic acid or vanillyl mandelic acid (VMA).

iii. VMA Estimation: Normal level of excretion of VMA is 2–6 mg / 24 hr. It is increased in pheochromocytoma (epinephrine excess) and in neuroblastoma (norepinephrine excess). Patient is asked to refrain from intake of chocolate, coffee, banana, vanilla ice-creams, citrus fruits (lime and orange). These items contain vanillin, which produces very high values of VMA in urine. Patient should not take aspirin and other drugs containing phenol ring. 24-hour urine is collected. This is because urinary excretion of VMA is not continuous.

   From urine, VMA is extracted by ethyl acetate. It is oxidized with metaperiodate to convert VMA to vanillin. This is extracted with toluene. The color is red at 360 nm. Nowadays, VMA is also estimated by antibody method.

iv. Homovanillic acid (HVA) in Urine: It is also called methoxy hydroxy phenyl acetic acid. HVA is the main urinary metabolite of DOPA and dopamine while VMA is of the NE pathway. 24-hour urine is collected. This is because urinary excretion of VMA is not continuous. From urine, VMA is extracted by ethyl acetate. It is oxidized with metaperiodate to convert VMA to vanillin. This is extracted with toluene. The color is red at 360 nm. Nowadays, VMA is also estimated by antibody method.

3. Synthesis of Thyroid Hormones

Tyrosine residues are iodinated to form 3-mono-iodo-tyrosine (MIT) and 3,5-di-iodo-tyrosine (DIT). These are coupled to give rise to 3,5,3′-tri-iodo-thyronine (T3) and 3,5,3′,5′-tetraiodo-thyronine or thyroxine (T4) (Chapter 47).

4. Tyramine

Tyrosine is decarboxylated to tyramine by intestinal bacteria. Tyramine is present in chocolate, cocoa, wine, dried fish, processed meat, buttermilk, cheese, yeast, beans, peas, papaya and peanut. These may precipitate an attack of migraine in susceptible individuals.

5. Clinical Manifestations

A. The classical PKU child is mentally retarded with an IQ of 50. About 20% inmates of lunatic asylum may have PKU.

B. Agitation, hyperactivity, tremors and convulsions are often manifested. This may be because phenylalanine interferes with neurotransmitter synthesis.

C. The child often has hypopigmentation, explained by the decreased level of tyrosine.

D. Phenyl lactic acid in sweat may lead to mousy body odor.

6. Laboratory Diagnosis

A. Blood phenylalanine: Normal level is 1 mg/dl. In PKU, the level is >20 mg/dl. This may be
This is based on the observation that the urine becomes black on standing when it becomes alkaline. Sir Archibald Garrod in 1902 reported that patients complain that their underwears are getting blackened. Garrod concluded that the disease is inherited and it is due to the deficiency of the enzyme required for further metabolism of homogentisic acid. Alkaptonuria and albinism are two inborn errors included in Garrod’s tetrad; the other two being pentosuria and cystinuria. Garrod introduced the term “inborn errors of metabolism” in 1908. The condition had been vividly described by Zactus Luxtanus in 1649. Egyptian mummies dating back 2000 BC had pigmented cartilages due to alkaptonuria.

Biochemical Defect

1. Alkaptonuria is an autosomal recessive condition with an incidence of 1 in 250,000 births.
2. The metabolic defect is the deficiency of homogentisate oxidase (step 4, Fig. 17.2 and item 2, Fig. 17.7). This results in excretion of homogentisic acid in urine.
3. It is compatible with fairly normal life. The only abnormality is the blackening of urine on standing. The homogentisic acid is oxidized by polyphenol oxidase to benzoquinone acetate (Fig.17.6). It is then polymerized to black colored alkaptone bodies.
4. By the 3rd or 4th decade of life, patient may develop ochronosis (deposition of alkaptone bodies in intervertebral discs, cartilages of nose, pinna of ear). Black pigments are deposited over the connective tissues including joint cavities to produce arthritis.
5. No specific treatment is required. But minimal protein intake with phenylalanine less than 500 mg/day is recommended.

PKU is recessive; the disease is manifested only in homozygous state. In heterozygous (carrier) state, the phenyl alanine hydroxylase enzyme is sufficient to metabolise normal levels of phenylalanine. But when phenyl alanine (4 g) is injected intravenously, the carriers will show increased level in the blood (phenyl alanine load test).
Diagnosis of Alkaptonuria
1. Urine becomes black on standing when it becomes alkaline. Blackening is accelerated on exposure to sunlight and oxygen. The urine when kept in a test tube will start to blacken from the top layer.
2. Ferric chloride test will be positive for urine.
3. Benedict's test is strongly positive. Therefore, alkaptonuria comes under the differential diagnosis of reducing substances in urine (Chapter 24).

ALBINISM
1. The Greek word, albino means white. Albinism is an autosomal recessive disease with an incidence of 1 in 20,000 population (Fig.17.7).
2. Tyrosinase is completely absent, leading to defective synthesis of melanin.
3. The ocular fundus is hypopigmented and iris may be grey or red. There will be associated photophobia, nystagmus and decreased visual acuity.
4. The skin has low pigmentation, and so skin is sensitive to UV rays. The skin may show presence of naevi and melanomas. Hair is also white.
5. Manifestations are less severe in tyrosinase positive type, where the abnormality is in the uptake of tyrosine by melanocytes.
6. Albinism may be produced by the following causes:
   a. Melanocyte deficiency secondary to a failure of melanoblasts to colonize the skin.
   b. Failure of melanocytes to form melanosomes.
   c. Due to tyrosinase deficiency, melanin is not produced in the melanosomes.
   d. Failure of melanosomes to form melanin owing to substrate deficiency.
   e. Failure of melanosomes to store melanin or to transport melanin to keratinocytes.
   f. Excessive destruction of functional melanosomes.

HYPERTYROSINEMIAS
Hepatorenal Tyrosinemia (Tyrosinemia Type I)
1. It is also called as tyrosinosis. It is an autosomal recessive condition with an incidence of 1.5 per 1,000 births. It is due to a deficiency of enzyme fumaryl acetoacetate hydrolase (No.6 in Fig.17.2 and item 3, Fig.17.7).
2. Symptoms manifest by the first 6 months of life and death occurs rapidly. Cabbage like odor and hypoglycemia and eventual liver failure are seen. There may be mild mental retardation.
3. Urine contains tyrosine, parahydroxy phenyl pyruvic acid (p-HPPA) and hydroxy phenyl lactic acid; and serum shows tyrosine.
4. Tyrosine and phenylalanine restricted diet is advised.

Oculocutaneous Tyrosinemia (Tyrosinemia Type II)
It is also known as Richner-Hanhart syndrome. It is due to deficiency of tyrosine amino transferase (tyrosine transaminase) (Step No.2, Fig.17.2). Mental retardation,
keratosis of palmar surface, painful corneal lesions and photophobia are seen. There is increased excretion of tyrosine and tyramine in urine. A diet low in protein is advised.

**Neonatal Tyrosinemia**

This is due to the absence of the enzyme para hydroxy phenyl pyruvate hydroxylase (step no.3, Fig.17.2). This deficiency may cause transient hypertyrosinemia in the new-born; this will respond to administration of ascorbic acid and dietary protein restriction.

A variant of the above disease is called **Heredity pHPPA Oxidase Deficiency**. This is a more aggressive condition. It is characterized by neurological abnormalities and excretion of tyrosine, para hydroxy phenyl pyruvic acid (pHPPA), hydroxy phenyl lactic acid and hydroxy phenyl acetic acid in urine.

**Hawkinsinuria**

It is an autosomal dominant trait, and is due to dysfunction of pHPPA oxidase. It is characterized by excretion of Hawkinsin in urine, a derivative of pHPPA.

A summary of phenyl alanine and tyrosine metabolism is shown in Figure 17.7.

**TRYPTOPHAN (TRP) (W)**

Substances produced from tryptophan are:
1. Alanine (glucogenic)
2. Acetoacetyl CoA (ketogenic)
3. Formyl group (One-carbon unit)
Chapter 17; Aromatic Amino Acids and Amino Acidurias

4. Niacin and NAD⁺
5. Serotonin
6. Melatonin
7. Hydroxy indole acetic acid (excretory product)
8. Indican (excretory product)

Major Catabolic Pathway of Tryptophan

i. In 1890, Ernst Stadelmann discovered tryptophan; Hopkins determined the structure in 1901, and established its essentiality for growth in 1906. Tryptophan is an aromatic, essential amino acid with an indole ring.

ii. The major metabolic fate of tryptophan is to be oxidized by tryptophan pyrrolase (tryptophan di-oxygenase) (Step 1, Fig. 17.8). It is a hemoprotein. The enzyme is inducible by corticosteroids.

iii. In this major pathway, the total 11 carbon atoms of tryptophan are catabolized as formyl group (1C which enters the one carbon pool), alanine (3C, entering the glucose pathway) and acetoacetate (4C, going to ketogenic pathway). So, tryptophan is both glucogenic and ketogenic. The remaining 3 carbons are removed as 3 CO₂ molecules.

iv. In the major pathway, kynureninase is an enzyme dependent on pyridoxal phosphate (enzyme 2, Fig.17.8). Therefore, in vitamin B₆ deficiency, the pathway is blocked at this level. This leads to niacin deficiency and manifestations of pellagra.

v. The accumulated kynurenine is shunted to xanthurenic acid. So, in pyridoxal deficiency, xanthurenic acid (Fig.17.8) is excreted in urine.

Nicotinic Acid Pathway of Tryptophan

i. About 97% molecules of tryptophan are metabolized in the major pathway. About 3% molecules are diverted at the level of 3-hydroxy anthranilic acid, to form NAD⁺ (Fig.17.9).

ii. The enzyme, QPRT (quinolinate phosphoribosyl transferase) (step 1, Fig.17.9) is the rate-limiting step.

iii. About 60 mg of tryptophan will be equivalent to 1 mg of nicotinic acid. The development of pellagra like symptoms (Chapter 34) in the maize eating population is due to tryptophan deficiency in maize.

iv. Hydroxy anthranilate production is dependent on pyridoxal phosphate (enzyme no. 2, Fig.17.8). Hence in vitamin B₆ deficiency, nicotinamide deficiency is also manifested.

Serotonin

i. Serotonin (5-hydroxy tryptamine) is produced in the brain, mast cells, platelets and gastrointestinal tract mucosa.

ii. Tryptophan is first hydroxylated by tryptophan hydroxylase (step 1, Fig.17.10). This reaction is very much similar to phenylalanine
hydroxylase (Fig. 17.1). The coenzyme is tetrahydrobiopterine. The tetrahydrobiopterin is regenerated using NADPH.

iii. In the next step, 5-hydroxy tryptophan is decarboxylated to 5-hydroxy tryptamine (5HT), (serotonin). The enzyme, decarboxylase requires pyridoxal phosphate (step 2, Fig. 17.10).

iv. The effect of serotonin is dependent on the amount of serotonin available at the synaptic site. Part of the serotonin released is again taken up (reuptake). Selective serotonin reuptake inhibitors (SSRI) are widely used in the treatment of psychiatric disorders.

v. Reference value of serotonin in blood in adult is 50-200 ng/ml. The level is increased in carcinoid tumors (>400 ng/ml), some oat cell tumors, dermoids, cystic teratoma, islet cell tumors, medullary thyroid tumors. It is decreased in Down’s syndrome, phenylketonuria, Parkinson’s disease, and severe depression.

Functions of Serotonin
1. Serotonin is an important neurotransmitter in brain. In brain cells, serotonin is in bound form. 5-HT is an antidepressant.
2. When ordinary proteins are taken, all amino acids are available in blood. This causes traffic jam in the amino acid transport systems in brain cells. Tryptophan, the bulkiest amino acid is therefore taken up very slowly.
3. However, when carbohydrate rich diet is taken, insulin secretion is increased, which will lower the amino acid concentration in blood. So tryptophan easily enters the brain cells. When tryptophan is available in brain in excess quantity, serotonin may be generated to induce sleep.
4. Carbohydrates will induce sleep, while protein rich foods will cause alertness.
5. Serotonin level is found to be low in patients with depressive psychosis. Serotonin is involved in mood, sleep, appetite and temperature regulation. It increases gastrointestinal motility.
6. Sensitivity to pain is reduced by serotonin.

Box 17.5. Melanin and Melatonin are Different

Melanin is the pigment of hair and skin; it is synthesized from Tyrosine (Fig. 17.3)

Melatonin is a neurotransmitter synthesized from Tryptophan (Fig. 17.10).

Catabolism of Serotonin
Monoamine oxidase (MAO) converts serotonin to 5-hydroxy indole acetic acid (HIAA) (step 3, Fig. 17.10). MAO will oxidatively deaminate compounds having an amino group attached to a carbon atom. This is similar to degradation of epinephrine (step 6, Fig. 17.4). MAO inhibitors (e.g. iproniazid) will cause mood elevation. Small portion of serotonin is conjugated with sulfate or with glucuronic acid, and excreted through urine.

Carcinoid Tumors
i. Serotonin is produced by argentaffin cells of the gastrointestinal tract and is necessary for GIT motility. These cells may grow into locally malignant argentaffinomas, otherwise known as carcinoid tumors. These tumors develop in small intestine or in the appendix.
ii. The patient complains of flushing, sweating, intermittent diarrhea and often has fluctuating hypertension.
iii. Normally, about 1% tryptophan molecules are channelled to serotonin synthesis. But in carcinoid syndrome, up to 60% is diverted to serotonin. Therefore, niacin deficiency (pellagra) may also be seen in carcinoid syndrome.
iv. HIAA (5-Hydroxy indole acetic acid) in Urine: After stopping all medications for 72 hours, collect random fresh urine. Exclude dietary sources of 5 HIAA (Avocado, banana, red plum, pineapple, tomato, cough syrup containing glycerol guaiacolate, drugs like indomethacin). Normal value is 2-7 mg/day. It is increased in carcinoid tumors in the gut or bronchus, tropical sprue, Whipple’s disease, oat cell carcinoma of the bronchus. If urine 5 HIAA exceeds 25 mg/day, diagnosis of carcinoid syndrome can be made. Metastatic carcinoid tumor (functioning) shows higher values (>350 mg/day). Since 5 HIAA secretion may be intermittent, repeated testing is required. It is decreased in depression, small intestinal resection, phenylketonuria and Hartnup disease.

Melatonin
i. Serotonin is acetylated (step 4, Fig.17.10).
ii. Further methylated with the help of S-adenosyl methionine (SAM) (step 5, Fig.17.10 and Box 17.5).
iii. Pineal gland produces melatonin. It is intimately connected with the diurnal variations, sleep wake cycles and the biological rhythms.
iv. Melatonin blocks MSH and ACTH secretions. The activity of melatonin as a neurotransmitter was discovered by Julius Axelrod who was awarded Nobel Prize in 1970.
v. Melatonin as regulator molecule: It acts both as a hormone of the pineal gland and as a local regulator molecule in various tissues. In mammals, various binding sites for melatonin have been identified, the membrane receptors MT(1) and MT(2), which are of utmost chronobiological importance, ROR and RZR isoforms as nuclear receptors, quinone reductase 2, calmodulin, calreticulin, and mitochondrial binding sites. The G protein-coupled receptors (GPCRs) MT(1) and MT(2) are capable of signaling via different G alpha subforms, in particular, G alpha (i) and G alpha (q), and via G beta-gamma. Multiple signaling can lead to the activation of different cascades and/or ion channels. Melatonin frequently decreases cAMP, but also activates phospholipase C and protein kinase C, acts via the MAP kinase and PI3 kinase/Akt pathways, modulates Ca(2+) and voltage-gated Ca(2+) channels.

Putrefaction of Tryptophan
Intestinal bacterial putrefaction of tryptophan results in the production of several indole compounds (Fig.17.11). These are mainly excreted in the feces as skatoxyl. Some part is absorbed, detoxified and excreted in urine as indoxyl and indican. Indican is the potassium salt of indoxyl sulfate. The foul smell of feces and the natural color of urine is due to these compounds. Normal excretion of indican in urine is 4-20 mg/day, which is increased in Hartnup's disease.

Liver and intestinal bacteria can convert tryptophan to tryptamine, and then to indole-acetate. The major urinary excretory products of tryptophan are 5-hydroxy indole acetate and indole-3-acetate.

Hartnup's Disease
i. The name originates after the first family in whom the disease was described. It is an inherited autosomal recessive disease.

ii. Absorption of aromatic amino acids from intestine as well as reabsorption from renal tubules are defective. So amino acids are excreted in urine.
iii. The pellagra like symptoms are due to the deficiency of niacin derived from tryptophan. The common manifestations are dermatitis and ataxia.
iv. A diagnosis is based on amino aciduria and increased excretion of indole compounds detected by the Obermeyer test.
v. Patients improve when put on a high protein diet with supplementation of niacin and minimum exposure to sunlight. The neuropsychiatric manifestations of Hartnup's disease are said to be responsible for the sadistic and bizarre behavior of emperors like Nero and Caligula.

A summary of Tryptophan metabolism is shown in Figure 17.12.
Proline (Pro) (P) and Hydroxyproline

Proline is a non-essential glucogenic amino acid. The catabolic pathway of proline is described in Figure 17.13. Proline does not participate in the transaminase reaction. Proline is made into glutamate, which enters the citric acid cycle for complete oxidation.

Proline dehydrogenase deficiency results in an inborn error of metabolism named as type II hyperprolinemia. Due to the deficiency of glutamate semialdehyde dehydrogenase, type II hyperprolinemia results. Both conditions are benign.

Proline can be synthesized from glutamic acid with minor modification of the catabolic pathway. For synthesis of proline, glutamate is first activated by phosphorylation with the help of ATP. Glutamate phosphate is reduced by NADPH to glutamate semialdehyde, which on removal of water will give rise to pyrroline-5-carboxylate. It has a double bond in the ring. It is further reduced with the help of NADPH to form proline.

Proline is incorporated into the protein, and then hydroxylated to hydroxy proline, by the enzyme prolyl hydroxylase. The hydroxylation requires molecular oxygen, ascorbate, iron and alpha ketoglutarate, which is decarboxylated to succinate. One atom of oxygen molecule is incorporated into proline and the other into succinate.

Hydroxyproline is catabolized more or less similar to proline. The pathway is, hydroxyproline to pyrroline-3-hydroxy-5-carboxylate, to hydroxy-glutamate semialdehyde, to hydroxy-glutamate, to keto-hydroxy glutarate, which is broken by an aldolase to glyoxalate and pyruvate. Deficiency of hydroxy proline dehydrogenase will lead to hyper hydroxy prolinemia. It is also a benign condition.

Proline and 4-hydroxy proline confer strength to fibrous proteins like collagen, elastin, keratin, etc. (Chapter 52). In vitamin C deficiency, hydroxyproline synthesis is reduced, causing decreased strength of fibers, leading to scurvy. The excretion of hydroxyproline in urine is increased in tumors infiltrating bones and in diabetic patients due to enhanced rate of protein catabolism.

Fate of Carbon Skeletons of Amino Acids

During catabolism of carbon skeletons, amino acids may enter into the TCA cycle, when they can be converted to glucose. In other words, those amino acids, which give rise to citric acid cycle intermediates can be made into glucose. Hence, those amino acids entering into TCA cycle, or at pyruvic acid level are called glucogenic amino acids. This is shown in Figure 17.14.

On the other hand, those amino acids which produce acetyl CoA are called ketogenic amino acids. Acetyl CoA entering into the TCA cycle is completely oxidized. Therefore, there is no net synthesis of glucose from acetyl CoA. So, acetyl CoA is not entering into the gluconeogenesis pathway. Acetyl CoA, however, can give rise to ketone bodies. Thus, amino acids entering as acetyl CoA are known as ketogenic amino acids. These amino acids are shown in Figure 17.14.

But some amino acids are shown in both the lists. Phenyl alanine, tyrosine, tryptophan and isoleucine are both glucogenic and ketogenic. This is because, during their metabolism, part of the carbon skeleton will enter into some of the TCA cycle intermediates; while the other part will generate acetyl CoA (see Figure 17.14).

AMINO ACIDURIAS

Amino acidurias are clinically very important. It is estimated that about 20 to 25% of the inmates of lunatic asylums are suffering from one of the amino acidurias. Most of them manifest as mental retardation. It is important to remember that the mental retardation could be prevented, if the condition is diagnosed immediately after the birth, and adequate treatment is started. Delay in diagnosis for each week will appreciably reduce the intelligence quotient. A selected list of amino acidurias is shown in Table 17.1.

Several inborn errors of metabolism with neurological defects are associated with cerebral dysmorphogenesis. This may be due to:

a. Accumulation of neurotoxic intermediate, e.g. nonketotic hyperglycinemia (NKH), sulfite oxidase deficiency
b. Defective energy metabolism; PDH deficiency
c. Defective membrane and cell signaling pathways, e.g. Smith's disease.
d. Defects of subcellular organelle, e.g. peroxisomal biogenesis disorders.

Reactions of the Cycle
Preparatory steps
Acetyl CoA enters the cycle, and is completely oxidized. During this process, energy is trapped. The sources of acetyl CoA are shown in Figure 18.1. Pyruvate derived from glycolysis is oxidatively decarboxylated to acetyl CoA by pyruvate dehydrogenase (Fig. 9.22). This is the link between the TCA cycle and glycolysis. The pyruvate dehydrogenase reaction occurs in the mitochondria. Pyruvate with the help of a carrier can enter the mitochondria from the cytoplasm. The acetyl CoA derived from beta oxidation is formed in the mitochondria itself. All the enzymes of citric acid cycle are located inside the mitochondria.

1st Step: Formation of Citric Acid
The 4 carbon, oxaloacetate condenses with 2 carbon, acetyl CoA to form 6 carbon compound, the citrate (a tricarboxylic acid). The enzyme is citrate synthase (step 1, Fig. 18.2). The hydrolysis of the thio-ester bond in acetyl CoA drives the reaction forward. This is an irreversible step. However, body can reverse this step by another enzyme, ATP-citrate lyase (see Fig.11.13).

2nd Step: Formation of Isocitrate
Citrate is isomerized to isocitrate by aconitase (Step 2, Fig.18.2). This reaction is a two-step process. At first, one water molecule is removed from
Fig. 18.2. Krebs cycle or citric acid cycle or tricarboxylic acid cycle

Acetyl CoA (2 carbon), enters the cycle. These are released as CO₂ in steps 3 and 4. So Acetyl CoA is completely oxidised by the time cycle reaches alpha ketoglutarate.

All reactions are readily reversible; except 1st and 4th steps
citrate forming cis aconitate, a transient compound with a very short half-life. Immediately, one water molecule is added to aconitate to form isocitrate. Thus the position of the hydroxyl group is shifted.

3rd Step: Formation of Alpha Ketoglutarate
i. This reaction is a two-step process, both catalyzed by the same enzyme, isocitrate dehydrogenase (Step 3, Fig. 18.2). In the first part of the reaction, isocitrate is dehydrogenated to form oxalosuccinate. It is an unstable compound which undergoes spontaneous decarboxylation to form alpha ketoglutarate.
ii. The NADH generated in this step is later oxidized in electron transport chain (ETC) to generate ATPs.
iii. Isocitrate (6 carbons) undergoes oxidative decarboxylation to form alpha ketoglutarate (5 carbons). In this reaction, one molecule of CO₂ is liberated.
iv. The isocitrate dehydrogenase has iso-enzymes; the mitochondrial form utilizes NAD⁺, while cytoplasmic enzyme is NADP⁺ dependent.

4th Step: Formation of Succinyl CoA
i. Next, alpha ketoglutarate is oxidatively decarboxylated to form succinyl CoA by the enzyme alpha ketoglutarate dehydrogenase (step 4, Fig. 18.2).

5th Step: Generation of Succinate
The next reaction involves a substrate level phosphorylation whereby a high energy phosphate is generated from the energy trapped in the thio-ester bond of succinyl CoA. The enzyme is succinate thiokinase (step 5, Fig. 18.2). A molecule of GDP is phosphorylated to GTP and succinate is formed. The GTP can be converted to ATP by reacting with an ADP molecule:

\[ \text{GTP + ADP} \rightarrow \text{GDP + ATP} \]

Succinyl CoA metabolism is shown in Figure 11.11 and Figure 34.13.

6th Step: Formation of Fumarate
Succinate is dehydrogenated to fumarate, an unsaturated dicarboxylic acid, by succinate dehydrogenase (step 6, Fig. 18.2). The hydrogen atoms are accepted by FAD. The \( \text{FADH}_2 \) then enters into ETC to generate ATPs. The enzyme is
Fig. 18.5. Summary of Krebs citric acid cycle. Enzymes are numbered. Reactions number 3 and 4 are carbon dioxide elimination steps. Physiological regulatory steps are: Step No.1 (citrate synthase) is physiologically inhibited by ATP. Step No.3 (ICDH) is inhibited by NADH and activated by ADP. Steps where energy is trapped are marked with the coenzyme and the number of ATP generated during that reaction. A total of 10 ATPs are generated during one cycle. Recent work shows that in the electron transport chain, NADH may produce only $2\frac{1}{2}$ ATPs and FADH only $1\frac{1}{2}$ ATPs.

7th Step: Formation of Malate
The formation of malate from fumarate is catalyzed by fumarase (step 7, Fig. 18.2). The reaction involves the addition of a water molecule. Only L-malate is formed.

8th Step: Regeneration of Oxaloacetate
Finally malate is oxidized to oxaloacetate by malate dehydrogenase (Step 8, Fig. 18.2). The co-enzyme is NAD$^+$. The NADH is generated in this step, which enters the electron transport chain, when ATPs are produced. The oxaloacetate can further condense with another acetyl CoA molecule and the cycle continues (Fig. 18.2).

Oxaloacetate as a junction point
i. Oxaloacetate may be viewed as a catalyst, which enters into the reaction, causes complete oxidation of acetyl CoA and comes out of it without any change.

ii. Oxaloacetate is an important junction point in metabolism. Various reactions of oxaloacetate are shown in Figure 18.4. Significance of citric acid cycle is shown in Box 18.1.

SIGNIFICANCE
1. Complete Oxidation of Acetyl CoA
CO$_2$ removal steps
During the citric acid cycle, two carbon dioxide molecules are removed in the following reactions:
A. Step 3, isocitrate (oxalosuccinate) to alpha ketoglutarate
B. Step 4, alpha ketoglutarate to succinyl CoA (Fig. 18.5).
Acetyl CoA contains 2 carbon atoms. These two carbon atoms are now removed as CO₂ in steps 3 and 4. Net result is that **acetyl CoA is completely oxidized during one turn of cycle**.

### 2. ATP Generating Steps in TCA Cycle

There are 3 NADH molecules generated during one cycle, each of them will give rise to 2 ½ ATPs on oxidation by electron transport chain (ETC); so altogether they will give $3 \times 2 \frac{1}{2} = 7 \frac{1}{2} (7.5)$ high energy phosphates. The FADH₂ will generate 1½ molecules of ATP. In addition, one molecule of GTP (equivalent to one molecule of ATP) is formed by **substrate level** phosphorylation. Hence, per turn of the cycle, **10 high energy** phosphates are produced. These steps are marked in Figure 18.5 and in Table 18.1. The summary is shown in Box 18.2.

Note: Recent work shows that in the electron transport chain, NADH produces only 2.5 ATPs and FADH only 1.5 ATPs. The old values (used in the previous editions of this textbook) are also given for comparison in Table 18.1.

Alpha ketoglutarate dehydrogenase reaction is the only one **irreversible step** in the cycle. The free energy changes of the reactions of the cycle are such that the cycle will operate spontaneously in the clockwise direction.

Only about 33% of energy liberated is trapped as ATP. The rest is used to keep the body temperature at a higher level than the environment.

### 3. Final Common Oxidative Pathway

Citric acid cycle may be considered as the final common oxidative pathway of all foodstuffs. As shown in Figure 18.9, all the major ingredients of foodstuffs are finally oxidized through the TCA cycle.

Almost all the biochemical processes use ATP for meeting energy needs—muscle contraction, active transport, biosynthetic reactions, etc. A thermodynamically unfavorable reaction when coupled with hydrolysis of ATP becomes favorable.

### 4. Integration of Major Metabolic Pathways

i. **Carbohydrates** are metabolized through glycolytic pathway to pyruvate, then converted to acetyl CoA, which enters the citric acid cycle.

ii. Fatty acids through beta oxidation, are broken down to acetyl CoA and then enter this cycle. 

iii. Glucogenic Amino acids after transamination enter at some points in this cycle (Fig.18.9). Ketogenic amino acids are converted into acetyl CoA. 

iv. The integration of metabolism is achieved at junction points by key metabolites (Fig.18.9). Ketogenic amino acids are converted into acetyl CoA. Several pathways can converge at this point with the result that carbon atoms from one source can be used for synthesis of another. Important intermediates are acetyl CoA and oxaloacetate (see Figs 18.1 and 18.4).

5. Fat is Burned on the Wick of Carbohydrates 
The oil in a lamp by itself cannot be lighted; the flame needs a wick (Fig.18.6). Similarly in the body, oxidation of fat (acetyl CoA) needs the help of oxaloacetate. One passage of cycle oxidizes acetyl CoA into two CO₂ molecules. Here oxaloacetate acts as a true catalyst; it enters the cycle and is regenerated in the end. The major source of oxaloacetate is pyruvate (carbohydrate). Hence carbo-hydrates are absolutely required for oxidation of fats, or fats are burned in the fire of carbohydrates. 

6. Excess Carbohydrates are Converted to Neutral Fat 
Excess calories are deposited as fat in adipose tissue. The pathway is glucose to pyruvate to acetyl CoA to fatty acid. However, fat cannot be converted to glucose because pyruvate dehydrogenase reaction (pyruvate to acetyl CoA) is an absolutely irreversible step (Fig.18.7).

7. No Net Synthesis of Carbohydrates from Fat 
Acetyl CoA entering in the cycle is completely oxidized to CO₂ by the time the cycle reaches succinyl CoA (Fig. 18.2). So, acetyl CoA is completely broken down in the cycle. Thus acetyl CoA cannot be used for gluconeogenesis. Therefore, there is no net synthesis of carbohydrates from fat (Fig. 18.7).

8. Amino Acids Finally Enter the TCA Cycle 
Some amino acids, such as leucine, catabolized to acetyl CoA; are not converted to glucose, because pyruvate to acetyl CoA reaction is irreversible. The acetyl CoA molecules either enter the TCA cycle and are completely oxidized, or are channeled to ketone body formation. Hence they are called as ketogenic amino acids (Fig. 18.9). Glucogenic amino acids also get converted to intermediates of TCA cycle.

9. Amphibolic Pathway 
All other pathways such as beta oxidation of fat or glycogen synthesis are either catabolic or anabolic. But TCA cycle is truly amphibolic (both catabolic and anabolic) in nature. (Greek, amphi = both).
Pyruvate can be carboxylated to malate by NADP+ dependent malic enzyme.

### Regulation of the Citric Acid Cycle

1. **Citrate and citrate synthase**
   The formation of citrate from oxaloacetate and acetyl CoA is an important part of control (step 1, Fig. 18.5). **ATP acts as an allosteric inhibitor of citrate synthase.** Citrate allosterically inhibits PFK, the key enzyme of glycolysis; stimulates fructose-1,6-bisphosphatase, a key enzyme of gluconeogenesis and activates acetyl CoA carboxylase, key enzyme of fatty acid synthesis.

2. **Availability and cellular need of ATP**
   When the energy charge of the cell is low, the cycle operates at a faster rate. **The cycle is tightly coupled to the respiratory chain providing ATP.** The Krebs cycle is the largest generator of ATP among metabolic pathways.

   **Anaerobiosis** (hypoxia) will inhibit ETC, when NADH and FADH2 are accumulated, which, in turn, will cause inhibition of TCA cycle.

3. **Isocitrate dehydrogenase**
   Step 3, (Fig. 18.5). ADP acts as a positive modifier enhancing the binding of substrate. NADH is an inhibitor.

4. **Alpha ketoglutarate dehydrogenase**
   It is inhibited by succinyl CoA and NADH.

### Inhibitors of TCA Cycle

The above-said mechanisms are physiological and regulatory in nature. But the following are toxic or poisonous (non-physiological) agents which inhibit the reactions. These are shown in Figure 18.5.

- **Aconitase** (citrate to aconitate) is inhibited by fluoro-acetate. This is non-competitive inhibition.
- **Alpha ketoglutarate dehydrogenase** (alpha ketoglutarate to succinyl CoA) is inhibited by Arsenite. This again is non-competitive inhibition.
- **Succinate dehydrogenase** (succinate to fumarate) is inhibited by malonate; this is competitive inhibition.

### Metabolic Defects Related to Krebs Cycle

Though extremely rare, some enzyme deficiency states have been found to affect the operation of TCA cycle. These are given in Table 18.2.

</tbody>
</table>

There is a continuous influx (pouring into) (Fig.18.9) and a continuous efflux (removal) of 4-carbon units from the TCA cycle (Fig.18.8). In a traffic circle, many roads converge and traffic flows towards one direction. Since various compounds enter into or leave from TCA cycle, it is sometimes called as "**metabolic traffic circle**". Important anabolic reactions related with citric acid cycle are:

- **a.** Oxaloacetate is the precursor of aspartate
- **b.** Alpha ketoglutarate can be made into glutamate
- **c.** Succinyl CoA is used for synthesis of heme
- **d.** Mitochondrial citrate is transported to cytoplasm, where it is cleaved into acetyl CoA, which then is the starting point of fatty acid synthesis (Fig.11.13).

### 10. Anaplerotic Role of TCA Cycle

The citric acid cycle acts as a source of precursors of biosynthetic pathways, e.g. heme is synthesized from succinyl CoA and aspartate from oxaloacetate. To counterbalance such losses, and to keep the concentrations of the 4-carbon units in the cell, anaplerotic reactions are essential. This is called anaplerotic role of TCA cycle (Greek word, ana = up; plerotikos = to fill). Anaplerotic reactions are "filling up" reactions or "influx" reactions or "replenishing" reactions which supply 4-carbon units to the TCA cycle (Fig. 18.9). The important anaplerotic reactions are:

- **a.** Pyruvate to oxaloacetate by pyruvate carboxylase enzyme (Fig. 9.24). It needs ATP.
- **b.** Glutamate is transaminated to alpha ketoglutarate; and aspartate to oxaloacetate. Other important amino acids entering the TCA cycle are shown in Figure 18.9.
The reader will be able to answer questions on the following topics:
1. Redox potentials
2. Biological oxidation
3. Enzymes and coenzymes
4. High energy compounds
5. Organization of electron transport chain
6. Chemi-osmotic theory
7. Proton pump
8. ATP synthase
9. Inhibitors of ATP synthesis

Stages of Oxidation of Foodstuffs

First Stage
Digestion in the gastrointestinal tract converts the macromolecules into small units. For example, proteins are digested to amino acids. This is called primary metabolism (Fig. 19.1).

Second Stage
The products of digestion are absorbed, catalyzed to smaller components, and ultimately oxidized to CO₂. The reducing equivalents are mainly generated in the mitochondria by the final common oxidative pathway, citric acid cycle. In this process, NADH and FADH₂ are generated. This is called secondary or intermediary metabolism.

Third Stage
These reduced equivalents (NADH and FADH₂) enter into the electron transport chain (ETC), or Respiratory chain, where energy is released. This is the tertiary metabolism or internal respiration or cellular respiration (Fig. 19.1). The energy production by complete oxidation of one molecule of glucose is 2850 kJ/mol and that of palmitate is 9781 kJ/mol. This energy is then used by body for synthetic reactions (Fig. 19.2).

Phototrophs harvest the energy of light (plants). Chemotrophs harvest energy from oxidation of fuel molecules. Principles of bioenergetics and thermodynamics are described in Chapter 1.

Redox Potentials
Redox potential of a system is the electron transfer potential $E_0$. Oxidation is defined as the loss of electrons and reduction as the gain in electrons. When a substance exists both in the reduced state and in the oxidized state, the pair is called a redox couple.

Fig. 19.1. Oxidation of foodstuffs in three stages

Fig. 19.2. ATP generation. Food is catabolized; energy from food is trapped as ATP; it is then used for anabolic reactions
The redox potential of this couple is estimated by measuring the electromotive force (EMF) of a sample half cell connected to a standard half cell. The sample half cell contains one molar solution each of the reductant and oxidant. The reference standard half cell has 1 M H⁺ solution in equilibrium with hydrogen gas at one atmosphere pressure. The reference half cell has a reduction potential of zero meV.

**Negative and Positive Redox Potential**

When a substance has lower affinity for electrons than hydrogen, it has a negative redox potential. If the substance has a positive redox potential, it has a higher affinity for electrons than hydrogen. Thus NADH, a strong reducing agent, has a negative redox potential (−0.32 V), whereas a strong oxidant like oxygen has a positive redox potential (+0.82 V). Table 20.1 gives the redox potentials of some of the important redox couples of the biological system. A summary is given in Box 19.1.

**Substrate Level Phosphorylation**

Here energy from a high energy compound is directly transferred to nucleoside diphosphate to form a triphosphate without the help of electron transport chain, e.g.

\[
\text{ATP generation is coupled with a more exergonic metabolic reaction.}
\]

**BIOLOGICAL OXIDATION**

The transfer of electrons from the reduced co-enzymes through the respiratory chain to oxygen is known as biological oxidation. Energy released during this process is trapped as ATP. This coupling of oxidation with phosphorylation is called **oxidative phosphorylation.** In the body, this oxidation is carried out by successive steps of dehydrogenations.

**Electron Transport Chain**

The electron flow occurs through successive dehydrogenase enzymes, together known as electron transport chain (ETC). **The electrons flow from electronegative potential (−0.32) to electropositive potential (+ 0.82).** A summary is shown in Figure 19.13.

**Energetics of Oxidative Phosphorylation**

The \( E'_0 \) and \( G^0' \) of biological oxidation may be calculated as follows:

\[
\frac{1}{2} \text{O}_2 + 2H^+ \rightarrow H_2O \quad (E'_0 = +0.82) \\
\text{NAD}^+ + H^+ + 2e \rightarrow \text{NADH} \quad (E'_0 = −0.32)
\]

When these two equations are computed;

\[
\frac{1}{2} \text{O}_2 + \text{NADH} + H^+ \rightarrow H_2O + \text{NAD}^+; E'_0 = 1.14 \text{ V}
\]

\[
\Delta G^0' = −nF E'_0 = −2 \times 23.06 \times 1.14 = −52.6 \text{ kcal/mol}
\]

The free energy change between NAD⁺ and water is equal to 53 kcal/mol. This is so great that, if this much energy is released at one stretch, body cannot utilize it. Hence with the help of ETC assembly, the total energy change is released in small increments so that energy can be trapped as **chemical bond energy, ATP** (Fig.19.2).

**ENZYMES AND COENZYMES**

All the enzymes involved in this process of biological oxidation belong to the major class of oxidoreductases. They can be classified into the following 5 headings:

1. **Oxidases**

These enzymes catalyze the removal of hydrogen from substrates, but only **oxygen can act as acceptor** of hydrogen, so that water is formed.

\[
\text{AH}_2 + \frac{1}{2} \text{O}_2 \rightarrow \text{A} + \text{H}_2\text{O}
\]
This group includes cytochrome oxidase (terminal component of ETC), tyrosinase, polyphenoloxidase, catechol oxidase and monoamine oxidase.

2. Aerobic Dehydrogenases
These enzymes catalyze the removal of hydrogen from a substrate, but oxygen can act as the acceptor. These enzymes are flavoproteins and the product is usually hydrogen peroxide.

\[ \text{AH}_2 + \text{O}_2 \rightarrow \text{A} + \text{H}_2\text{O}_2 \]

These flavoproteins contain either FMN or FAD as prosthetic group. Examples are L-amino acid oxidase which catalyses the oxidative deamination of L-amino acids (Fig. 14.10) and Xanthine oxidase (Fig. 39.15).

3. Anaerobic Dehydrogenases
These enzymes catalyze the removal of hydrogen from a substrate but oxygen cannot act as the hydrogen acceptor. They, therefore, require coenzymes as acceptors of the hydrogen atoms. When the substrate is oxidized, the coenzyme is reduced.

3-a. NAD\(^+\) linked dehydrogenases: NAD\(^+\) is derived from nicotinic acid, a member of the vitamin B complex (see Chapter 34). When the NAD\(^+\) accepts the two hydrogen atoms, one of the hydrogen atoms is removed from the substrate as such. The other hydrogen atom is split into one hydrogen ion and one electron. The electron is also accepted by the NAD\(^+\) so as to neutralize the positive charge on the coenzyme molecule. The remaining hydrogen ion is released into the surrounding medium (Fig. 19.3).

\[ \text{H}_2 \rightarrow \text{H}^+ + \text{e}^- \]
\[ \text{AH}_2 + \text{NAD}^+ \rightarrow \text{A} + \text{NADH} + \text{H}^+ \]

The NAD\(^+\) linked dehydrogenases are (Fig.19.13):

i. Glyceraldehyde-3-phosphate dehydrogenase
ii. Isocitrate dehydrogenase
iii. Malate dehydrogenase
iv. Glutamate dehydrogenase
v. Beta hydroxy acyl CoA dehydrogenase
vi. Pyruvate dehydrogenase
vii. Alpha keto glutarate dehydrogenase

3-b. NADP\(^+\) linked dehydrogenases: NADPH cannot be oxidized with concomitant production of energy. These are taking part in reductive biosynthetic reactions like fatty acid synthesis and cholesterol synthesis. An example of NADPH linked dehydrogenase is the glucose-6-phosphate dehydrogenase (Fig.10.1)

3-c. FAD-linked dehydrogenases: When FAD is the coenzyme, (unlike NAD\(^+\)), both the hydrogen atoms are attached to the flavin ring. Examples:
   i. Succinate dehydrogenase (step 6, Fig.18.2)
   ii. Fatty acyl CoA dehydrogenase (Fig.11.9)
   iii. Glycerolphosphate dehydrogenase (Fig.19.6)

3-d. Cytochromes: All the cytochromes, except cytochrome oxidase, are anaerobic dehydrogenases. (Cytochrome oxidase is an oxidase, see above). All cytochromes are hemoproteins having iron atom. Cytochrome b, cytochrome c1, and cytochrome c are in mitochondria while cytochrome P-450 and cytochrome b5 are in endoplasmic reticulum.

4. Hydroperoxidases
4-a. Peroxidase: Examples of peroxidases are glutathione peroxidase in RBCs (a selenium containing enzyme), leukocyte peroxidase and horse radish peroxidase. Peroxidases remove free radicals like hydrogen peroxide (see Chapter 20).

\[ \text{H}_2\text{O}_2 + \text{AH}_2 \rightarrow \text{2H}_2\text{O} + \text{A} \]

4-b. Catalase: Catalases are hemoproteins. Peroxisomes are subcellular organelles having both aerobic dehydrogenases and catalase.

\[ \text{2H}_2\text{O}_2 \rightarrow \text{2H}_2\text{O} + \text{O}_2 \]

5. Oxygenases
5-a. Mono-oxygenases: These are otherwise called mixed function oxidases. Here, one oxygen atom is incorporated into the substrate and the other oxygen atom is reduced to water. These enzymes are also called hydroxylases because OH group is incorporated into the substrate.

\[ \text{A-H} + \text{O}_2 + \text{BH}_2 \rightarrow \text{A-OH} + \text{H}_2\text{O} + \text{B} \]

i. Phenylalanine hydroxylase
ii. Tyrosine hydroxylase
iii. Tryptophan hydroxylase (Fig. 17.10)
iv. Microsomal cytochrome P-450 mono-oxygenase is concerned with drug metabolism.

v. Mitochondrial cytochrome P-450 mono-oxygenase.
The figure "450" denotes that it absorbs light at 450 nm, when the heme combines with carbon monoxide. It is required for steroid hydroxylation in adrenal cortex, testis and ovary.

v. Nitric oxide synthase (Fig. 16.6).

5-b. Di-oxygenases: They are enzymes which incorporate both atoms of a molecule of oxygen into the substrate, e.g. tryptophan pyrrolase and homogentisic acid oxidase (Fig. 17.8).

A + O₂ → AO₂

HIGH ENERGY COMPOUNDS

These compounds when hydrolyzed will release a large quantity of energy, that is, they have a large ΔG⁰. The high energy bond in compounds is usually indicated by a squiggly bond (~). The free energy of hydrolysis ΔG⁰ of an ordinary bond varies from ~1 to ~6 kcal/mol. For example, glucose-6-phosphate has a free energy of only 13.8 kJ/mol (~3.3 kcal/mol).

On the other hand, the free energy of high energy bonds varies from >25 kJ/mol (~7 to ~15 kcal/mol). High energy compounds are listed in Table 19.2.

### Adenosine Triphosphate (ATP)

i. ATP is the **universal currency of energy** within the living cells. Structure of ATP is shown in Figure 5.3.

ii. The hydrolysis of ATP to ADP (under standard conditions) releases \(-30.5 \text{ kJ/mol or } -7.3 \text{ kcal/mol}\) \((ΔG⁰ = -7.3)\). The energy in the ATP is used to drive all endergonic (biosynthetic) reactions. The energy efficiency of the cell is comparable to any machine so far invented. ATP captures the chemical energy released by the combustion of nutrients and transfers it to synthetic reactions that require energy.

iii. At rest, Na⁺-K⁺-ATPase (see Chapter 2) uses up one-third of all ATP formed. Other energy requiring processes are, biosynthesis of macromolecules, muscle contractions, cellular motion using kinesin, dyenin, etc.

iv. ATP is continually being hydrolyzed and regenerated. An average person at rest consumes and regenerates ATP at a rate of approximately 3 molecules per second, i.e. about 1.5 kg/day!

At this juncture, it is interesting to review different types of reactions undergone by ATP.

1. Glucose + ATP → Glucose-6-phosphate + ADP
   Here ATP is hydrolyzed to ADP level and phosphate is incorporated in the product (Fig. 9.5).

2. Pyruvate + CO₂ + ATP → Oxaloacetate + ADP + Pi
   Here ATP is hydrolyzed to ADP level, but phosphate is released (Fig. 9.24).

3. Fatty acid + CoA + ATP → Fatty acyl CoA + AMP + PPi
   The ATP is hydrolyzed to AMP level, but pyrophosphate is released (Fig. 11.9).

4. Ribose-5-P+ATP → Phosphoribosyl pyrophosphate + AMP
   Although ATP is hydrolyzed to AMP level, the pyrophosphate is added to the substrate (Fig. 39.11).

The figure "450" denotes that it absorbs light at 450 nm, when the heme combines with carbon monoxide. It is required for steroid hydroxylation in adrenal cortex, testis and ovary.

Yellapragada Subba Row (1895-1948). His article is the 4th most cited paper in the world literature. Born in Andhra Pradesh, he studied medicine in Madras, and conducted research at USA. He discovered ATP, assayed phosphates and isolated tetracyclins and many other drugs.
5. Amino acid + ATP $\rightarrow$ Aminoacyl adenylate + PPi
Here AMP group is incorporated into the product (see Chapter 41).

6. Methionine + ATP $\rightarrow$ S-adenosyl methionine + PPi + Pi
Here adenosyl group is incorporated into the product (see Fig. 15.14).

Cyrus Fiske and Yellapragada Subba Row discovered ATP in 1929; Karl Lohmann showed its importance in muscle contraction in 1929. In 1941, Fritz Lipmann (Nobel Prize, 1953) showed that ATP is the universal carrier of chemical energy in the cell and coined the expression "energy rich phosphate bonds". Alexander Todd (Nobel Prize, 1957) elucidated its structure.

**Creatine Phosphate**
Phosphocreatine (Creatine phosphate or CP) provides a high energy reservoir of ATP to regenerate ATP rapidly by the Lohmann’s reaction, catalyzed by creatine kinase.

$$\text{ATP} + \text{Creatine} \rightarrow \text{Phosphocreatine} + \text{ADP} + \Delta G^0 = 43.1 \text{ kJ/mol} (-10.5 \text{ kcal/mol})$$

The reaction is mitochondrial and of special significance in the myocardium which has a high energy requirement, about 6 kg of ATP per day. Energy transfer to the heart’s myofibrils is by creatine kinase energy shuttle, since being a smaller molecule than ATP, CP can rapidly diffuse from the myocardium to the myofibrils.

Storage forms of high energy phosphates, such as creatine phosphate and arginine phosphate are called Phosphagens. Creatine phosphate is mainly seen in skeletal muscle, heart, and brain.

**Structure of Mitochondrion**
The electron transport chain is functioning inside the mitochondria. The mitochondrion is a subcellular organelle having the outer and inner membranes enclosing the matrix (Fig. 19.4). The inner membrane is highly selective in its permeability, containing specific transport proteins. Certain enzymes are specifically localized in mitochondria (Table 19.3). The inner membrane contains the respiratory chain and translocating systems. The knob like protrusions represent the ATP synthase system (Fig. 19.4).

**ORGANIZATION OF ELECTRON TRANSPORT CHAIN**
i. In the electron transport chain, or respiratory chain, the electrons are transferred from NADH to a chain of electron carriers. The electrons flow from the more electronegative components to the more electropositive components.

ii. All the components of electron transport chain (ETC) are located in the inner membrane of mitochondria.

iii. There are four distinct multi-protein complexes; these are named as complex-I, II, III and IV. These are connected by two mobile carriers, co-enzyme Q and cytochrome C.

iv. The arrangement is schematically represented in Figure 19.7. The sequence of reaction is depicted in Box 19.2.

**NADH Generation**
The NADH is generated during intermediary metabolism (Fig. 19.13). A detailed list of the reactions using NADH is given in Box 34.3.
Malate Aspartate Shuttle
Mitochondrial membrane is impermeable to NADH. The NADH equivalents generated in glycolysis are therefore to be transported from cytoplasm to mitochondria for oxidation. This is achieved by malate-aspartate shuttle or malate shuttle, which operates mainly in liver, kidney and heart. The cycle is operated with the help of enzymes *malate dehydrogenase* (MDH) and *aspartate amino transferase* (Fig.19.5). From one molecule of NADH in the mitochondria, 2½ ATP molecules are generated.

Glycerol-3-phosphate Shuttle
In skeletal muscle and brain, the reducing equivalents from cytoplasmic NADH are transported to mitochondria as FADH₂ through glycerol-3-phosphate shuttle (Fig. 19.6). Hence only 1½ ATPs are generated when this system is operating.

1. ETC Complex-I
i. It is also called *NADH-CoQ reductase* or *NADH dehydrogenase complex*. It is tightly bound to the inner membrane of mitochondria.
ii. It contains a flavoprotein (Fp), consisting of FMN as prosthetic group and an iron-sulphur protein (Fe-S). NADH is the donor of electrons, FMN accepts them and gets reduced to FMNH₂ (Fig.19.8). Two electrons and one hydrogen ion are transferred from NADH to the flavin prosthetic group of the enzyme.

\[
\text{NADH} + \text{H}^+ + \text{FMN} \rightarrow \text{FMNH}_2 + \text{NAD}^+ 
\]

iii. The electrons from FMNH₂ are then transferred to Fe-S. The electrons are then transferred to coenzyme Q (ubiquinone) (CoQ).

iv. Overall function of this complex is to collect the pair of electrons from NADH and pass them to CoQ. The reactions are shown in Fig. 19.8.

v. There is a large negative free energy change; the energy released is 12 kcal/mol. This is utilized to drive 4 protons out of the mitochondria.

2. Complex II or Succinate-Q-Reductase
The reaction in Complex-II is represented in Fig.19.9. The electrons from FADH₂ enter the ETC at the level of coenzyme Q. This step does not liberate enough energy to act as proton pump. In other words, substrates oxidized by FAD-linked enzymes bypass complex-I.

The three major enzyme systems that transfer their electrons directly to ubiquinone from the FAD prosthetic group are:

i. Succinate dehydrogenase, (step 6, Fig.18.2)
ii. Fatty acyl CoA dehydrogenase (step 1, Fig.11.9)
iii. Mitochondrial glycerol phosphate dehydrogenase (Fig.19.6).
3. Coenzyme Q
   i. The ubiquinone (Q) is reduced successively to semiquinone (QH) and finally to quinol (QH₂).
   ii. It accepts a pair of electrons from NADH or FADH₂ through complex-I or complex-II respectively (see Figs 19.7 and 19.13).
   iii. Coenzyme Q is a quinone derivative having a long isoprenoid tail. The chain length of the tail is different in various species, mammals have 10 isoprene units (Fig. 19.10). Two molecules of cytochrome c are reduced.
   iv. The Q cycle thus facilitates the switching from the two electron carrier ubiquinol to the single electron carrier cytochrome c.

4. Complex III or Cytochrome Reductase
   i. This is a cluster of iron-sulphur proteins, cytochrome b and cytochrome c₁, both contain heme prosthetic group. The sequence of reaction inside the Complex III is shown in Figure 19.11.
   ii. During this process of transfer of electron, the iron in heme group shuttles between Fe³⁺ and Fe²⁺ forms.
   iii. The free energy change is –10 kcal/mol; and 4 protons are pumped out.

5. Cytochrome c
   It is a peripheral membrane protein containing one heme prosthetic group. The term cytochrome is derived from Greek, meaning cellular colors. It is one of the highly conserved proteins among different species. Axel Theorell (Nobel Prize, 1955) isolated it. Cytochrome c collects electrons from Complex III and delivers them to Complex IV.

6. Complex IV or Cytochrome Oxidase
   i. It contains different proteins, including cytochrome a and cytochrome a₃. The Complex IV is tightly bound to the mitochondrial membrane.
   ii. The reaction is depicted in Figure 19.12. Four electrons are accepted from cytochrome c, and passed on to molecular oxygen.
   \[
   4 \text{H}^+ + \text{O}_2 + 4 \text{Cyt.C-Fe}^{++} \rightarrow 2 \text{H}_2\text{O} + 4 \text{Cyt.C}^{+++}
   \]
   iii. 2 protons are pumped out to the intermembrane space.
   iv. Cytochrome oxidase has 4 redox centers, namely, a, a₃, CuA and CuB. The electron transfer in this complex is as shown
Cyto c → CuA → Cyto a → Cyto a3 → CuB

Cytochrome oxidase contains 2 heme groups and 2 copper ions. The two heme groups are denoted as cytochrome-a and cytochrome a-3. The functional unit of the enzyme is a single protein, and is referred to as cytochrome a--a3.

The sequential arrangement of members of electron transport chain is shown in Box 19.2 and Figure 19.13.

**P:O Ratio**
The P:O ratio is defined as the number of inorganic phosphate molecules incorporated into ATP for every atom of oxygen consumed. When a pair of electrons from NADH reduces an atom of oxygen (½ O₂), 2.5 mol of ATP are formed per 0.5 mol of O₂ consumed. This results in harnessing of energy required for production of only 2.5 ATP from NADH and 1.5 ATP from FADH₂.

**Current Concept, Energetics of ATP Synthesis**
The free energy released by electron transport through complex I to IV must be conserved in a form that ATP synthase can perform energy coupling. The energy of electron transfer is used to drive protons out of the matrix by the complexes I, III and IV that are proton pumps. The proton gradient thus created is maintained across the inner mitochondrial membrane till electrons are transferred to oxygen to form water. The electrochemical potential of this gradient is used to synthesize ATP.

According to the estimated free energy of synthesis, it was presumed that around 3 protons are required per ATP synthesized. Hence when one NADH transfers its electrons to oxygen, 10 protons are pumped out. This would account for the synthesis of approximately 3 ATP. Similarly the oxidation of 1 FADH₂ is accompanied by the pumping of 6 protons, accounting for 2 molecules of ATP. However, Peter Hinkle recently proved that the actual energy production is less, because there is always leakage of protons. This results in harnessing of energy required for the production of 2.5 ATP from NADH and 1.5 ATP from FADH₂.

The synthesis of one ATP molecule is driven by the flow of 3 protons through the ATP synthase (see below). When NADH is oxidized, 10 hydrogen ions (protons) are pumped out (Fig. 19.13). According to recent findings, one NADH may generate only 2.5 ATP; and one FADH₂ may generate only 1.5 ATP. So, one molecule of glucose will generate only 32 ATPs. The traditional values and the new values are compared in Table 19.4. (Please note that there is no change in the values of ATP generation by substrate level phosphorylation).

Energy efficiency of glucose oxidation giving 32 molecules of ATP and palmitate giving 106 molecules of ATP is given as 34% and 33% respectively.

**Sites of ATP Synthesis**
Traditionally, the sites of ATP synthesis are marked, as site 1, 2 and 3, as shown in Figure 19.13. But now it is known that ATP synthesis actually occurs when the proton gradient is dissipated, and not when the protons are pumped out (Fig. 19.15).

CHEMI-OSMOTIC THEORY
The coupling of oxidation with phosphorylation is termed oxidative phosphorylation. Peter Mitchell in 1961 (Nobel Prize, 1978) proposed this theory to explain the oxidative phosphorylation. The transport of protons from inside to outside of inner mitochondrial membrane is accompanied by the generation of a proton gradient across the membrane. Protons (H\(^+\) ions) accumulate outside the membrane, creating an electrochemical potential difference (Fig.19.15). This proton motive force drives the synthesis of ATP by ATP synthase complex (Fig.19.14).

PROTON PUMP AND ATP SYNTHESIS
The proton pumps (complexes I, III and IV) expel H\(^+\) from inside to outside of the inner membrane.

---

Fig. 19.14. ATP synthase. Protons from outside pass through the pore of Fo into the matrix, when ATP is synthesized.

So, there is high H\(^+\) concentration outside the inner membrane. This causes H\(^+\) to enter into mitochondria through the channels (Fo); this proton influx causes ATP synthesis by ATP synthase A summary is shown in Figure 19.15.
The pH outside the mitochondrial inner membrane is 1.4 units lower than inside. Further, outside is positive relative to the inside (+0.14 V). See Fig. 19.15. The proton motive force (PMF) is 0.224 V corresponding to a free energy change of 5.2 kcal/mol of protons.

**ATP SYNTHASE (COMPLEX V)**

It is a protein assembly in the inner mitochondrial membrane. It is sometimes referred to as the 5th Complex (Figs 19.14 and 19.15). Proton pumping ATP synthase (otherwise called F1-Fo ATPase) is a multisubunit transmembrane protein. It has two functional units, named as F1 and Fo. It looks like a lollipop since the membrane embedded Fo component and F1 are connected by a protein stalk.

**Fo Unit:** The "o" is pronounced as "oh"; and not as "zero". The "o" stands for oligomycin, as Fo is inhibited by oligomycin. Fo unit spans inner mitochondrial membrane. It serves as a proton channel, through which protons enter into mitochondria (Fig. 19.14). Fo unit has 4 polypeptide chains and is connected to F1. Fo is water insoluble whereas F1 is a water soluble peripheral membrane protein.

**F1 Unit:** It projects into the matrix. It catalyses the ATP synthesis (Fig. 19.14). F1 unit has 9 polypeptide chains, (3 alpha, 3 beta, 1 gamma, 1 sigma, 1 epsilon). The alpha chains have binding sites for ATP and ADP and beta chains have catalytic sites. ATP synthesis requires Mg**+** ions.

**Mechanism of ATP synthesis:** Translocation of protons carried out by the Fo catalyses the formation of phospho-anhydride bond of ATP by F1. Coupling of the dissipation of proton gradient with ATP synthesis (oxidative phosphorylation) is through the interaction of F1 and Fo.

**Binding Change Mechanism**

The binding change mechanism proposed by Paul Boyer (Nobel Prize, 1997) explains the synthesis of ATP by the proton gradient. The ATP synthase is a "molecular machine", comparable to a ‘water-driven hammer, minting coins’. Fo is the wheel; flow of protons is the waterfall and the structural changes in F1 lead to ATP coin being minted for each turn of the wheel. The F1 has 3 conformation states for the alpha-beta functional unit:

- **O state** - Does not bind substrate or products
- **L state** - Loose binding of substrate and products
- **T state** - Tight binding of substrate and products

According to this theory, the 3 beta subunits (catalytic sites), are in three functional states: **O form** is open and has no affinity for substrates. **L form** binds substrate with sluggish affinity. **T form** binds substrate tightly and catalyses ATP synthesis.

As protons translocate to the matrix, the free energy is released, and this is harnessed to interconvert these 3 states. The bond is synthesized in the T state and ATP is released in the O state. The sequence of events is as follows.
1. ADP and Pi bind to L binding site
2. L → T conversion is by energy driven conformational change that catalyses the formation of ATP
3. T state reverts to O state when ATP is released.
4. L state is regenerated for further ADP binding.

For the complete rotation of F1 head through the 3 states, 10 protons are translocated.

Protons entering the system, cause conformational changes in the F1 particle. Initially the ADP and Pi are loosely bound to the catalytic site on F1. As the Fo accepts protons, the affinity for ADP is increased (step 1, Fig. 19.16). Further conformational change induces catalytic activity, and ATP is synthesized (step 2, Fig. 19.16). This moves protons to the matrix side. As the ATPs are released, the original conformation of the enzyme is assumed (step 3, Fig. 19.16). Then ADP is again bound and the cycle repeats (step 4, Fig. 19.16). The energy surplus produced by the proton gradient is stored as chemical energy in ATP. The energy requiring step is not at the synthesis of ATP, but energy is required for the conformational changes.

**Regulation of ATP Synthesis**

The availability of ADP regulates the process. When ATP level is low and ADP level is high, oxidative phosphorylation proceeds at a rapid rate. This is called *respiratory control* or acceptor control. The major source of NADH and FADH2 is the citric acid cycle, the rate of which is regulated by the energy charge of the cell.

**INHIBITORS OF ATP SYNTHESIS**

a. Site Specific Inhibitors: (Table 19.5; Fig. 19.17)
b. Inhibitors of Oxidative Phosphorylation:

b-i. **Atractyloside** inhibits the translocase whereas **oligomycin** inhibits the Fo (Table 19.5).

b-ii. Ionophores are lipid soluble compounds that increase the permeability of lipid bilayers to certain ions. There are two types of ionophores; mobile ion carries (e.g. **valinomycin**) and channel formers (e.g. **gramicidin**). Valinomycin allows potassium to permeate mitochondria and dissipate the proton gradient.

b-iii. The toxicity of cyanide is due to its inhibitory effect on the terminal cytochrome which brings cellular respiration to a standstill.

c. **Uncouplers of Oxidative Phosphorylation:** Uncouplers will allow oxidation to proceed, but the energy instead of being trapped by phosphorylation

is dissipated as heat. This is achieved by removal of the proton gradient. (Table 19.5; Fig. 19.17).

The uncoupling of oxidative phosphorylation is useful biologically. In hibernating animals and in newborn human infants, the liberation of heat energy is required to maintain body temperature. In **Brown adipose tissue**, thermogenesis is achieved by this process.

**Thermogenin**, a protein present in the inner mitochondrial membrane of adipocytes, provides an alternate pathway for protons. It is one of the uncoupling proteins (UCP).

**Thyroxine** is also known to act as a physiological uncoupler.

**Mitochondrial Transport Systems**
The inner membrane is highly selective in its permeability characteristics. So, there are several transmembrane protein systems, to transport specific molecules in and out of the mitochondrial membrane. Some important transporters are shown in Figure 19.18. Pyruvate carrier is a symport system (pyruvate and hydrogen ions to same side). Tricarboxylate carrier is an antiport system, carrying malate and citrate in the opposite directions (Fig. 19.18). Certain enzymes are specifically localized in mitochondria (Table 19.3).

**Creatine Phosphate Shuttle**
ATP generated inside the mitochondria is brought outside the mitochondria by the creatine phosphate shuttle (Fig. 19.19).
ATP is first transported through inner mitochondrial membrane by adenine nucleotide transporter. Then the high energy bond of ATP is exchanged with creatine by mitochondrial iso-enzyme of creatine kinase. The creatine phosphate thus generated is then transported through the pores of outer mitochondrial membrane. Inside the cytoplasm, creatine phosphate is again exchanged with ATP by muscle iso-enzyme of creatine kinase.

Diseases Associated with Mitochondria
Mitochondrial DNA is inherited cytoplasmically and is therefore transmitted maternally (Table 41.6). OXPHOS (oxidative phosphorylation) diseases are described in Chapter 41. Mutations in mitochondrial DNA are responsible for the following diseases.
1. Lethal infantile mitochondrial ophthalmoplegia
2. Leber's hereditary optic neuropathy (LHON)
3. Myoclonic epilepsy
4. Mitochondrial encephalomyopathy lactic acidosis stroke like episodes (MELAS)

Unlike nuclear DNA, there are hundreds of copies of mitochondrial genes per cell (heteroplasy). Leber’s hereditary optic myopathy is characterised by blindness in young males. It is caused by a single base mutation in NADH Coenzyme Q reductase. Streptomycin induced deafness is also found to be due to a mutation in the mitochondrial rRNA.

Mitochondrial Permeability Transition Pore (MPTP)
Cytochrome C is also the mediator of apoptosis (programmed cell death). Since cytochrome C is a peripheral membrane protein, it is loosely bound to mitochondria. So, it is released from the mitochondria when the mitochondrial membrane permeabilization (MMP) occurs. This can happen in response to an oxidant stress due to ROS, increase in calcium concentration in mitochondria or any other form of stress. As the membrane permeability increases, there is transient opening of a mitochondrial permeability transition pore (MPTP). However, if the injury is only transient, the pore closes.
But if the pore remains open, it results in dissipation of mitochondrial proton gradient, ATP depletion and release of cytochrome C. This cytochrome C acts as a trigger for apoptosis by forming an apoptosome complex with other pro-apoptotic factors. The initiator caspase is then activated leading to activation of effector caspases, and finally the cell death in the intrinsic pathway (see Fig.19.20).

Reperfusion injury can also result from generation of ROS which leads to activation (opening ) of MPTP and resultant events can lead to necrosis. In myocardial and cerebral ischemia, the core of the damaged tissue undergoes necrosis, but the surrounding tissue which is not initially damaged can undergo delayed apoptosis.

MPTP is located at the contact site between the inner and outer mitochondrial membranes. It is made up of Voltage Dependent Anion Channel (VDAC) located in the outer membrane, Adenine Nucleotide Translocase (ANT) located in the inner membrane and Cyclophilin–D (CyP-D).
CHAPTER 20

Free Radicals and Anti-Oxidants

CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:
1. Reactive oxygen species
2. Generation of free radicals
3. Damage produced by free radicals
4. Free radical scavenger enzyme systems
5. Clinical significance
6. Lipid peroxidation
7. Anti-oxidants

The outermost orbital in an atom or molecule contains two electrons, each spinning in opposite directions. The chemical covalent bond consists of a pair of electrons, each component of the bond donating one electron each.

Definition
A free radical is a molecule or molecular fragment that contains one or more unpaired electrons in its outer orbital (Fig. 20.1). Free radical is generally represented by a superscript dot, (R•).

Oxidation reactions ensure that molecular oxygen is completely reduced to water. The products of partial reduction of oxygen are highly reactive and create havoc in the living systems. Hence, they are also called Reactive oxygen species or ROS. The following are members of this group:

i. Superoxide anion radical (O2•−) (Fig. 20.2)

ii. Hydroperoxyl radical (HOO•) (Fig. 20.2)

Out of this, hydrogen peroxide and singlet oxygen are not free radicals (they do not have superscript dot). However, because of their extreme reactivity, they are included in the group of reactive oxygen species (Table 20.1).

iii. Hydrogen peroxide (H2O2) (Fig. 20.2)

iv. Hydroxyl radical (OH•) (Fig. 20.2)

v. Lipid peroxide radical (ROO•)

vi. Singlet oxygen (1O2)

vii. Nitric oxide (NO•)

viii. Peroxy nitrite (ONOO•−).

Fig. 20.2. Some free radicals. Please compare hydroxyl radical (free radical) with hydroxyl ion, which is not a free radical. Also compare oxygen with superoxide anion.

Fig. 20.3. Generation of ROS in macrophages.
The sequential univalent reduction steps of oxygen may be represented as:

\[
O_2 (\rightarrow e^-) \rightarrow O_2^- (\rightarrow e^- \cdot 2H^+) \rightarrow H_2O_2 \rightarrow OH^- (\rightarrow e^- \cdot H^+) \rightarrow H_2O
\]

Important characteristics of the ROS are:

- a. Extreme reactivity.
- b. Short life span.
- c. Generation of new ROS by chain reaction.
- d. Damage to various tissues.

**Generation of Free Radicals**

i. They are constantly produced during the normal oxidation of foodstuffs, due to leaks in the electron transport chain in mitochondria. About 1–4% of oxygen taken up in the body is converted to free radicals. Mitochondrial ROS production is modulated largely by the rate of electron flow through respiratory chain complexes.

ii. Some enzymes such as xanthine oxidase (Fig. 39.15) and aldehyde oxidase form superoxide anion radical or hydrogen peroxide.

iii. NADPH oxidase in the inflammatory cells (neutrophils, eosinophils, monocytes and macrophages) produces superoxide anion by a process of respiratory burst during phagocytosis (Fig. 20.3). The superoxide is converted to hydrogen peroxide and then to hypochlorous acid (HClO) with the help of superoxide dismutase (SOD) and myeloperoxidase (MPO). The superoxide and hypochlorous ions are the final effectors of bactericidal action. This is a deliberate production of free radicals by the body. Along with the activation of macrophages, the consumption of oxygen by the cell is increased drastically; this is called respiratory burst.

In chronic granulomatous disease (CGD), the NADPH oxidase is absent in macrophages and neutrophils. In this condition, macrophages ingest bacteria normally, but cannot destroy them. However, streptococci and pneumococci themselves produce \( H_2O_2 \). Therefore, they are destroyed by the myeloperoxidase system of the macrophages. But staphylococci being catalase positive can detoxify \( H_2O_2 \) in the macrophages and therefore are not destroyed in such persons. Hence, recurrent pyogenic infection by staphylococci are common in chronic granulomatous disease.

iv. Macrophages also produce NO from arginine by the enzyme nitric oxide synthase (Fig. 16.6). This is also an important anti-bacterial mechanism.

v. Peroxidation is also catalyzed by lipo-oxygenase in platelets and leukocytes.

vi. Ionizing radiation damages tissues by producing hydroxyl radicals, hydrogen peroxide and superoxide anion.

\[
H_2O \rightarrow (\text{gamma, UV radiation}) \rightarrow H^+ + OH^-
\]

vii. Light of appropriate wavelengths can cause photolysis of oxygen to produce singlet oxygen.

viii. The capacity to produce tissue damage by \( H_2O_2 \) is minimal when compared to other free radicals (by definition, \( H_2O_2 \) is not a free radical). But in presence of free iron, \( H_2O_2 \) can generate \( OH^+ \) (hydroxyl radical) which is highly reactive (Fig. 20.5).

ix. Cigarette smoke contains high concentrations of various free radicals.

x. Inhalation of air pollutants will increase the production of free radicals. These facts are summarized in Figure 20.4.

xi. Under hypoxic conditions, the mitochondrial respiratory chain also produce nitric oxide.

Free Radical Scavenger Systems

1. Superoxide dismutase (SOD)
The reaction is depicted in Figure 20.6. The mitochondrial SOD is manganese dependent; cytoplasmic enzyme is copper-zinc dependent. SOD is a non-heme protein. A defect in SOD gene is seen in patients with amyotrophic lateral sclerosis (Lou Gehrig’s disease; named after the American baseball captain who succumbed to the illness).

2. Glutathione peroxidase
In the next step, the H₂O₂ is removed by glutathione peroxidase (POD) (Fig. 20.6). It is a selenium dependent enzyme.

3. Glutathione reductase
The oxidized glutathione, in turn, is reduced by the glutathione reductase (GR), in presence of NADPH (Fig. 20.6). This NADPH is generated with the help of glucose-6-phosphate dehydrogenase (GPD) in HMP shunt pathway (Fig. 10.1). Therefore in GPD deficiency, the RBCs are liable to lysis, especially when oxidizing agents are administered (drug induced hemolytic anemia).

4. Catalase
When H₂O₂ is generated in large quantities, the enzyme catalase is also used for its removal.

\[
\text{Catalase} \quad 2 \text{H}_2\text{O}_2 \rightarrow \text{O}_2 + 2 \text{H}_2\text{O}
\]

**Fig. 20.4.** Formation of free radicals (NO), which can generate other reactive nitrogen species (RNS). Excess ROS and RNS can lead to oxidative and nitrosative stress. Low levels of both species function in hypoxic signaling pathways, which have important implications for cancer, inflammation and a variety of other diseases.

**Fig. 20.5.** Reactions involved in ROS. Note: Fenton reaction and Haber-Weiss reactions are dependent on iron.

**Fig. 20.6.** Free radical scavenging enzymes. SOD = super oxide dismutase. POD = peroxidase. GSH = glutathione. GR = glutathione reductase. GPD = glucose-6-phosphate dehydrogenase.
5. Polyphenols
Consumption of polyphenol-rich fruits, vegetables, and beverages is beneficial to human health. Dietary polyphenols represent a wide variety of compounds that occur in fruits, vegetables, wine, tea and chocolate. They contain flavones, isoflavones, flavonols, catechins and phenolic acids. They act as agents having antioxidant, anti-apoptosis, anti-aging, anticarcinogenic, anti-inflammatory, anti-atherosclerotic effect. They are protective against cardiovascular diseases. Work from author’s lab suggests that grape polyphenols can prevent brain damage due to alcohol. Oral administration of grape polyphenol extract ameliorates cerebral ischemia induced neuronal damage. Grape-seed procyanidins prevent low-grade inflammation by modulating cytokine expression in rats.

Damage Produced by Reactive Oxygen Species
Free radicals are extremely reactive. Their mean effective radius of action is only 30 Å. Their half-life is only a few milliseconds.

When a free radical reacts with a normal compound, other free radicals are generated. This chain reaction leads to thousands of events (see propagation phase below).

Peroxidation of PUFA (poly unsaturated fatty acids) in plasma membrane leads to loss of membrane functions. Lipid peroxidation and consequent degradation products such as malon dialdehyde (-CHO-CH2-CHO-) are seen in biological fluids.

Almost all biological macromolecules are damaged by the free radicals (Fig. 20.7). Thus, oxidation of sulfhydryl group containing enzymes, loss of function and fragmentation of proteins are noticed. Polysaccharides undergo degradation.

DNA is damaged by strand breaks. The DNA damage may directly cause inhibition of protein and enzyme synthesis and indirectly cause cell death or mutation and carcinogenesis (Fig. 20.7).

**CLINICAL SIGNIFICANCE**

1. **Chronic Inflammation**
Chronic inflammatory diseases such as rheumatoid arthritis are self-perpetuated by the free radicals released by neutrophils. ROS induced tissue damage appears to be involved in pathogenesis of chronic ulcerative colitis, chronic glomerulonephritis, etc.

2. **Acute Inflammation**
At the inflammatory site, activated macrophages produce free radicals. Respiratory burst and increased activity of NADPH oxidase are seen in macrophages and neutrophils.

3. **Respiratory Diseases**
Breathing of 100% oxygen for more than 24 hrs produces destruction of endothelium and lung edema. This is due to the release of free radicals by activated neutrophils.

In premature newborn infants, prolonged exposure to high oxygen concentration is responsible for bronchopulmonary dysplasia.

Adult respiratory distress syndrome (ARDS) is characterized by pulmonary edema. It is produced when neutrophils are recruited to lungs which subsequently release free radicals.

Cigarette smoke contains free radicals. Soot attracts neutrophils to the site which releases more free radicals, leading to lung damage.

4. **Diseases of the Eye**
Retrolental fibroplasia (retinopathy of prematurity) is a condition seen in premature infants treated with pure oxygen for a long time. It is caused by free radicals, causing thromboxane release, sustained vascular contracture and cellular injury.

Cataract formation is related with aging process. Cataract is partly due to photochemical generation of free radicals. Tissues of the eye, including the lens, has high concentration of free radical scavenging enzymes.

---

![Figure 20.7. Damages by reactive oxygen species](image-url)
5. Reperfusion Injury
Reperfusion injury after myocardial ischemia is caused by free radicals. During ischemia, the activity of xanthine oxidase is increased. When reperfused, this causes conversion of hypoxanthine to xanthine and superoxide anion. At the same time, the availability of scavenging enzymes is decreased, leading to aggravation of myocardial injury (Fig. 20.8).

Allopurinol, a xanthine oxidase inhibitor, reduces the severity of reperfusion injury.

6. Atherosclerosis and Myocardial Infarction
Low density lipoproteins (LDL) are deposited under the endothelial cells, which undergo oxidation by free radicals. This attracts macrophages. Macrophages are then converted into foam cells. This initiates the atherosclerotic plaque formation (see Chapter 25). Anti-oxidants offer some protective effect.

7. Shock-related Injury
Release of free radicals from phagocytes damage membranes by lipid peroxidation. They release leukotrienes from platelets and proteases from macrophages. All these factors cause increased vascular permeability, resulting in tissue edema. Anti-oxidants have a protective effect.

8. Skin Diseases
Certain plant products, called psoralens are administered in the treatment of psoriasis and leukoderma. When the drug is applied over the affected skin and then irradiated by UV light, singlet oxygen is produced with clinical benefit.

9. Carcinogenesis and Treatment
Free radicals produce DNA damage, and accumulated damages lead to somatic mutations and malignancy.

Cancer is treated by radiotherapy (see Chapter 53). Irradiation produces reactive oxygen species in the cells which trigger the cell death.

10. Aging Process
Reactive oxygen metabolites (ROM) play a pivotal role in the degenerative brain disorders such as Parkinsonism, Alzheimer’s dementia and multiple sclerosis. Cumulative effects of free radical injury cause gradual deterioration in aging process.

Lipid Peroxidation
1. Initiation Phase
Polyunsaturated fatty acids (PUFA) present in cell membranes are easily destroyed by peroxidation. During the initiation phase, the primary event is the production of \( R' \) (carbon centered radical) (PUFA radical) or \( \text{ROO}' \) (lipid peroxide radical) by the interaction of a PUFA molecule with free radicals generated by other means (Fig. 20.9).

\[
\text{RH} + \text{OH}' \rightarrow \text{R'} + \text{H}_2\text{O} \quad (\text{Reaction 1-A})
\]

\[
\text{ROOH} \rightarrow \text{ROO}'+ \text{H}^+ \quad (\text{Reaction 1-B})
\]

The \( R' \) and \( \text{ROO}' \), in turn, are degraded to malondialdehyde (3 carbon). It is estimated as an indicator of fatty acid breakdown by free radicals.

2. Propagation Phase
The carbon centered radical (\( R' \)) rapidly reacts with molecular oxygen forming a peroxyl radical (\( \text{ROO}' \)) which can attack another polyunsaturated lipid molecule.

\[
\text{R'} + \text{O}_2 \rightarrow \text{ROO}' \quad (\text{Reaction No.2})
\]

\[
\text{ROO}'+ \text{RH} \rightarrow \text{ROOH} + \text{R}' \quad (\text{Reaction No.3})
\]

The net result of reactions 2 and 3 is the conversion of \( R' \) to ROOH (a hydroperoxide). But there is simultaneous conversion of a carbon centered radical to a peroxyl radical, \( \text{ROO}' \). This would lead to continuous production of hydroperoxide with consumption of equimolecular quantities of PUFA. One free radical generates another free radical in the neighboring molecule; a "chain reaction" or "propagation" is initiated. This is sometimes called "death kiss" by free radicals. Accumulation of such lipid damages lead to the destruction of fine architecture, and integrity of the membranes.

3. Termination Phase
The reaction would proceed unchecked till a peroxyl radical reacts with another peroxyl radical to form inactive products.
**Fig. 20.9.** Peroxidation of poly unsaturated fatty acids

\[
\text{ROO}' + \text{ROO}' \rightarrow \text{RO}--\text{OR} + \text{O}_2 \quad \text{(Reaction 4-A)}
\]
\[
\text{R}' + \text{R}' \rightarrow \text{R}--\text{R} \quad \text{(Reaction 4-B)}
\]
\[
\text{ROO}' + \text{R}' \rightarrow \text{RO}--\text{OR} \quad \text{(Reaction 4-C)}
\]

**Role of Anti-Oxidants**

Apart from the scavenging enzymes described earlier, there are two types of anti-oxidants:

- **a. Preventive anti-oxidants:** They will inhibit the initial production of free radicals. They are catalase, glutathione peroxidase, and ethylene diamine tetra-acetate (EDTA).

- **b. Chain breaking anti-oxidants:** They can inhibit propagative phase. They include superoxide dismutase, uric acid and vitamin E. **Alpha tocopherol** (T-OH) (vitamin E) would intercept the peroxyl free radical and inactivate it before a PUFA can be attacked.

\[
\text{T-OH} + \text{ROO}' \rightarrow \text{TO}^* + \text{ROOH} \quad \text{(Reaction 5)}
\]

The phenolic hydrogen of the alpha tocopherol reacts with the peroxyl radical, converting it to a hydroperoxide product. The tocopheroxyl radical thus formed is stable and will not propagate the cycle any further.

The tocopheroxyl radical can react with another peroxyl radical getting converted to inactive products.

**Vitamin E** (Alpha tocopherol) acts as the most effective naturally occurring chain breaking anti-oxidant in tissues. Vitamin E is described in Chapter 33. Only traces of tocopherol is required to protect considerable amounts of polyunsaturated fat (1 tocopherol molecule per 1000 lipid molecules). But it is seen from reaction 5 and 6 that while acting as anti-oxidant, alpha tocopherol is consumed. Hence, it has to be replenished by daily dietary supply.

**Anti-oxidants**

1. **Vitamin E** is the lipid phase antioxidant.
2. **Vitamin C** is the aqueous phase antioxidant.
3. **Ceruloplasmin** can act as an antioxidant in extracellular fluid (Chapter 28).
4. **Caffeine** is another effective anti-oxidant.
5. Cysteine, glutathione and **vitamin A** are minor anti-oxidants. **Beta carotene** can act as a chain breaking antioxidant, but is less effective than alpha tocopherol.

**Anti-oxidants used as therapeutic agents**

1. Vitamin E
2. Vitamin C
3. Dimethyl thio urea
4. Dimethyl sulfoxide
5. Allopurinol

**Commercial Use of Anti-oxidants**

Anti-oxidants are regularly used in food industry to increase the shelf-life of products. Commercially used **food preservatives** are Vitamin E, propyl gal late, butylated hydroxy anisole (BHA) and butylated hydroxy toluene (BHT). They prevent oxidative damage of oils, particularly those containing PUFA and prevent rancidity.

**Related Topics**

Details of nitric oxide are described in Chapter 16.
Red blood cells (RBC) are biconcave discs, with a diameter of about 7 microns. RBCs live for about 120 days in peripheral circulation, during which time they traverse about 160 km! In a 70 Kg person, there will be about 25 x 10^{12} RBCs and 750 g of hemoglobin (Hb). 100 ml blood contains about 14.5 g of Hb. Mature RBC is non-nucleated; have no mitochondria and does not contain TCA cycle enzymes. However, the glycolytic pathway is active which provides energy and 2,3-bisphosphoglycerate (2,3-BPG). The HMP shunt pathway provides the NADPH. Human erythropoietin, a glycoprotein with molecular weight of 34 kD, is the major stimulator of erythropoiesis. It is synthesized in kidney and is released in response to hypoxia. RBC formation in the bone marrow requires amino acids, iron, copper, folic acid, vitamin B_{12}, vitamin C, pyridoxal phosphate and pantothenic acid; they are used as hematinsics in clinical practice.

FUNCTION OF HEME

Hemoglobin is a conjugated protein having heme as the prosthetic group and the protein, the globin. It is a tetrameric protein with 4 subunits, each subunit having a prosthetic heme group and the globin polypeptide.

The polypeptide chains are usually two alpha and two beta chains. Hemoglobin has a molecular weight of about 67,000 Daltons. Each gram of Hb contains 3.4 mg of iron. Heme is present in

- Hemoglobin
- Myoglobin
- Cytochromes
- Peroxidase
- Catalase
- Tryptophan pyrrolase
- Nitric oxide synthase

Heme is produced by the combination of iron with a porphyrin ring. Chlorophyll, the photosynthetic green pigment in plants is magnesium-porphyrin complex.

Structure of Heme

i. Heme is usually pronounced as “heem”. Heme is a derivative of the porphyrin. Porphyrins are cyclic compounds formed by fusion of 4 pyrrole rings linked by methenyl (=CH–) bridges (Fig. 21.1).

ii. Since an atom of iron is present, heme is a ferroprotoporphyrin. The pyrrole rings are named as I, II, III, IV and the bridges as alpha,
Table 21.1. Porphyrins of biological importance. See also Figure 21.3 for the structure of heme

</tbody>
</table>

(A = acetyl; P = propionyl; M = methyl; V = vinyl)

beta, gamma and delta. The possible areas of substitution are denoted as 1 to 8 (Fig. 21.2).

iii. When the substituent groups have a symmetrical arrangement (1,3,5,7 and 2,4,6,8) they are called the I series. The III series have an asymmetrical distribution of substituent groups (1,3,5,8 and 2,4,6,7).

iv. Type III is the most predominant in biological systems. It is also called series 9, because Fischer, the pioneer in porphyrin chemistry has placed it as the 9th in a series of 15 possible isomers. Hans Fischer synthesized heme in laboratory in 1920 (Nobel prize, 1930). The usual substitutions are:

a. propionyl (–CH₂–CH₂–COOH) group
b. acetyl (–CH₂–COOH) group
c. methyl (–CH₃) group
d. vinyl (–CH=CH₂) group.

Complete structure of heme is shown in Figure 21.3.

BIOSYNTHESIS OF HEME

Heme can be synthesized by almost all the tissues in the body. Heme is synthesized in the normoblasts,

but not in the matured erythrocytes. The pathway is partly cytoplasmic and partly mitochondrial.

Step 1: ALA synthesis

The synthesis starts with the condensation of succinyl CoA and glycine in the presence of pyridoxal phosphate to form delta amino levulinc acid (ALA) (Fig. 21.4). Hence anemia may be manifested in pyridoxal deficiency. The enzyme ALA synthase is located in the mitochondria and is the rate-limiting enzyme of the pathway.

Step 2: Formation of PBG

Next few reactions occur in the cytoplasm. Two molecules of ALA are condensed to form porphobilinogen (PBG). The condensation involves removal of 2 molecules of water and the enzyme is ALA dehydratase (Fig. 21.5, step 2). Porphobilinogen is a monopyrrole. The enzyme contains zinc and is inhibited by lead.

Step 3: Formation of UPG

Condensation of 4 molecules of the PBG, results in the formation of the first porphyrin of the pathway, namely uroporphyrinogen (UPG). Condensation occurs in a head-to-tail manner, so that a linear tetrapyrrrole is produced; this is named as hydroxy methyl bilane (HMB). The enzyme for this reaction is PBG-deaminase (otherwise called Uroporphyrin I synthase or HMB synthase). HMB molecule will cyclise spontaneously to form uroporphyrinogen I. It is converted to uroporphyrinogen III by the
enzyme, uroporphyrinogen III synthase. When the fusion occurs, the III series of isomers are predominantly formed; and only the III series are further utilized. The pyrrole rings are joined together by methylene bridges (-CH2-), which are derived from the alpha carbon of glycine. During this deamination reaction 4 molecules of ammonia are removed (Fig. 21.5, step 3). Porphyrinogens are colorless, but are readily oxidized to porphyrins, which are colored compounds.

Step 4: Synthesis of CPG
The UPG-III is next converted to coproporphyrinogen (CPG-III) by decarboxylation. Four molecules of CO₂ are eliminated by uroporphyrinogen decarboxylase. The acetate groups (CH₃-COOH) are decarboxylated to methyl (CH₃) groups (Fig. 21.5, step 4).

Step 5: Synthesis of PPG
Further metabolism takes place in the mitochondria. CPG is oxidized to protoporphyrinogen (PPG-III) by coproporphyrinogen oxidase. This enzyme specifically acts only on type III series, and not on type I series. Two propionic acid side chains are

Fig. 21.6. Summary of heme biosynthesis. The numbers denote the enzymes. Part of synthesis is in mitochondria, and the rest in cytoplasm.
Chapter 21; Heme Synthesis and Breakdown

oxidatively decarboxylated to vinyl groups (step 5, Fig. 21.5). This reaction requires molecular oxygen.

Step 6: Generation of PP
The Protoporphyrinogen-III is oxidized by the enzyme protoporphyrinogen oxidase to protoporphyrin-III (PP-III) in the mitochondria. The oxidation requires molecular oxygen. The methylene bridges (–CH₂) are oxidised to methenyl bridges (–CH=) and colored porphyrins are formed. Protoporphyrin-9 is thus formed.

Step 7: Generation of Heme
The last step in the formation of heme is the attachment of ferrous iron to the protoporphyrin. The enzyme is heme synthase or ferrochelatase which is also located in mitochondria.

Iron atom is coordinately linked with 5 nitrogen atoms (4 nitrogen of pyrrole rings of protoporphyrin and 1st nitrogen atom of a histidine residue of globin). The remaining valency of iron atom is satisfied with water or oxygen atom (Fig. 21.7). A summary of the pathway is shown in Figure 21.6.

When the ferrous iron (Fe⁺⁺) in heme gets oxidized to ferric (Fe⁺⁺⁺) form, hematin is formed, which loses the property of carrying the oxygen. Heme is red in color, but hematin is dark brown.

Regulation of Heme Synthesis
1. ALA synthase is regulated by repression mechanism. Heme inhibits the synthesis of ALA synthase by acting as a co-repressor (Fig. 42.8).
2. ALA synthase is also allosterically inhibited by hematin. When there is excess of free heme, the Fe⁺⁺ is oxidized to Fe⁺⁺⁺ (ferric), thus forming hematin.

3. The compartmentalization of the enzymes (Fig. 21.6) of heme synthesis makes the regulation easier for the regulation. The rate-limiting enzyme is in the mitochondria. The steps 1, 5, 6, and 7 are taking place inside mitochondria, while the steps 2, 3 and 4 are in cytoplasm.

4. Drugs like barbiturates induce heme synthesis. Barbiturates require the heme containing cytochrome p450 for their metabolism. Out of the total heme synthesized, two thirds are used for cytochrome p450 production.

5. The steps catalyzed by ferrochelatase and ALA dehydratase are inhibited by lead.

6. INH (Isonicotinic acid hydrazide) that decreases the availability of pyridoxal phosphate may also affect heme synthesis.

7. High cellular concentration of glucose prevents induction of ALA synthase. This is the basis of administration of glucose to relieve the acute attack of porphyrias.

8. ALA synthase (ALAS) have both erythroid and non-erythroid (hepatic) forms. Erythroid form is called ALAS2; it is not induced by the drugs that affect ALAS1. Erythroid form is not subject to feedback inhibition by heme.

Shunt Bilirubin
When ¹⁵N or ¹⁴C labelled glycine is injected, this is incorporated into heme and into RBCs. After 100-120 days, when RBCs are lysed, the radio-labelled Hb level is decreased, along with consequent rise in radioactive bilirubin. However, about 15% of radioactive bilirubin is excreted within about 10 days (Fig. 21.8). This is called Shunt bilirubin. This is the formation of bilirubin from heme in bone marrow, without being incorporated into Hb. This is the result of ineffective erythropoiesis. In porphyrias, especially in the erythropoietic varieties, the shunt bilirubin will be increased.

Disorders of Heme Synthesis
Porphyrias are a group of inborn errors of metabolism associated with the biosynthesis of heme. (Greek ‘porphyria’ means purple). These are characterized by increased production and excretion of porphyrins and/or their precursors (ALA + PBG). Most of the porphyrias are inherited...

PBG = Porphobilinogen; CP = Coproporphyrin; ALA = delta amino levulinic acid; UP = uroporphyrins. (Enzyme numbers are given as shown in Figure 21.9)

as autosomal dominant traits (Table 21.2). Porphyrias may be broadly grouped into 3 types:
a. Hepatic porphyrias
b. Erythropoietic porphyrias
c. Porphyrias with both erythropoietic and hepatic abnormalities.

This classification is based on the major site, where the enzyme deficiency is manifested. The clinical manifestations vary. Porphyrias in general, are not associated with anemia.

**Acute Intermittent Porphyria (AIP)**

1. It is inherited as an autosomal dominant trait. PBG-deaminase (uporphyrinogen-I-synthase) is deficient (Table 21.2 and Fig. 21.9).
2. This leads to a secondary increase in activity of ALA synthase, since the end-product inhibition is not effective.
3. The levels of ALA and PBG are elevated in blood and urine. As they are colorless compounds, urine is colorless when voided, but the color is increased on standing due to photo-oxidation of PBG to porphobilin. Hence urine samples for PBG estimation should be freshly collected and transported in dark bottles. Porphyrins are not excreted or elevated in blood; so there is no photosensitivity.
4. As the name indicates, the symptoms appear intermittently and they are quite vague. Hence it is at times called the "little imitator". Most commonly, patients present with acute abdominal pain. The patients often land up with the surgeon as a case of acute abdomen and on several instances exploratory laparotomies had been done.
5. Women have less severe manifestations before menarche and after menopause. Thus, the female sex hormones have a stimulatory effect on ALA synthase.
6. An attack is precipitated by starvation and symptoms are alleviated by a high carbohydrate diet. Drugs like barbiturates, which are known to induce ALA synthase, can precipitate an attack.
7. Another group may have neurological manifestations like sensory and motor disturbances, confusion and agitation. Some patients may present with psychiatric problems and may be treated accordingly. It is said that King George III (1760-1820) was suffering from mania due to porphyria. Many of his obstinate decisions, including the ones which led to war of American independence, were made when he had acute attacks of intermittent porphyria.

**ALA synthase (ALAS) deficiency**

It is the key enzyme of the pathway (see enzyme No.1 in Fig. 21.9). It is inhibited by heme in nonerythroid cells. Defective gene leads to **Pyridoxine responsive sideroblastic anemia**. Administration of porpyrinogenic drugs (barbiturates, ethanol, anticonvulsants) depletes heme; so feedback inhibition on ALAS is removed. This in turn leads to excessive production of heme intermediaries causing neurological porphyrias. Porphyrin precursors and porphyrins in urine and feces are normal. Definitive diagnosis is by demonstration of mutation in erythroid ALA synthase.

**ALA dehydratase (Porphobilinogen synthase) deficiency**

See enzyme No. 2 in Figure 21.9. This condition is very rare. Features are similar to AIP (abdominal pain and neuropathy). Differential diagnosis are lead poisoning (inhibit ALA dehydratase) and tyrosinemia Type I (accumulation of succinyl acetone which is structurally similar to ALA). Characteristic features are increased plasma ALA, increased urine ALA and coproporphyrin III, decreased ALAD in erythrocytes. Prenatal diagnosis is by ALAD activity in cultured chorionic villi.

### Congenital Erythropoietic Porphyria

It is inherited as an autosomal **recessive** trait (Table 21.2). (See enzyme No. 3b in Figure 21.9). Normally the type III isomer is produced in larger amounts, but in this condition, type I isomer is formed considerably. They are converted to porphyrins type I. This would lead to ineffective feedback inhibition which further increases the rate of formation of type I porphyrins. Their level in blood increases leading to photosensitivity. Their excretion in urine makes the urine dark red in color (port wine appearance). The major manifestations relate to the skin due to the photo-

</tbody>
</table>
sensitization by the presence of porphyrins in the capillaries. Reactive oxygen species (free radicals) are the cause for cell destruction (Chapter 20). Repeated attacks of dermatitis and scarring lead to a typical facial deformity often referred to as ‘monkey face’. Repeated ulceration and scarring may cause mutilation of nose, ear and cartilage. This may mimic leprosy. When UV light is reflected on to teeth a red fluorescence is seen; this is called erythrodontia.

**Ferrochelatase deficiency (Erythropoietic protoporphyria)**

See enzyme No.7 in Figure 21.9. It is characterized by increased free protoporphyrin in RBC and decreased ferrochelatase activity in cultured lymphocytes. RBCs exhibit red fluorescence at 620 nm.

Accumulation of porphyrin precursors, ALA and porphobilinogen leads to neurovisceral manifestations. Accumulated uroporphyrin and coproporphyrin cause delayed bullous lesions. On the other hand, being more lipophilic, protoporphyrin associates with cell membranes and causes burning sensation and inflammatory reaction in skin exposed to sun. Hence biochemical diagnosis of porphyria will be considered based on the major clinical features, namely: (a) neurovisceral (Table 21.3) and (b) cutaneous (Table 21.4) manifestations. The salient features of different types of porphyrrias are given in Tables 21.2 to 21.4).

**Acquired Porphyrias**

Porphyria can result from lead poisoning. Most of the paints contain lead more than the permitted levels. Children suck painted toys; and they get the poison. Causes of acquired porphyrias are listed in Table 21.5. The toxic effect of lead is due to inhibition of ferrochelatase. So, there is decreased level of heme with consequent increased activity of ALA synthase. A characteristic difference from congenital porphyrrias is that there is associated anemia in the acquired variety.

**Diagnosis of Porphyrias**

To demonstrate porphyrins, UV fluorescence is the best technique. The presence of porphyrin precursor in urine is detected by Ehrlich’s reagent. When urine is observed under ultraviolet light; porphyrins if present, will emit strong red fluorescence. The diagnostic importance of the heme precursors is shown in Table 21.6.

**Porphyrins and Absorption Bands**

In porphyrins, the 4 pyrrole rings are joined by methenyl (-CH=) bridges and they are colored compounds. The iron atom in the centre of porphyrin is hexavalent and bonded to the 4 pyrrole nitrogens by coordinate valencies. The double bonds are resonating and therefore keep shifting their position. When the ferrous iron (Fe++) in heme gets oxidized to ferric (Fe+++ ) form, hematin is formed, which loses the property of carrying the oxygen. Heme is red in color, but hematin is dark brown. When hemoglobin or porphyrin solutions are viewed through a spectroscope, the absorbed wave lengths are seen as dark bands. All porphyrins will have an absorption band near 400 nm; this distinguishing band is called the **Soret band**, after its discoverer. Table 21.7 shows the absorption bands of porphyrins.

**Box 21.1. Bile Pigments and Bile Salts**

Bile pigments are Bilirubin and Biliverdin. They are the breakdown products of heme; they are useless excretory products.

Bile salts are the sodium salts of bile acids (glycocholate and taurocholate). They are produced from cholesterol; they help in the absorption of fat.

Both bile pigments and bile salts are present in the bile.

**Fig. 21.10. Catabolic pathway of hemoglobin**
CATABOLISM OF HEME

1. Generation of Bilirubin

i. The end-products of heme catabolism are bile pigments (See Box 21.1). Bilirubin has no function in the body and is excreted through bile. The senescent RBCs breakdown liberating the hemoglobin.

ii. From hemoglobin, the globin chains are separated, they are hydrolyzed and the amino acids are channelled into the body amino acid pool. The iron liberated from heme is reutilized (Fig. 21.10).

iii. The porphyrin ring is broken down in reticuloendothelial (RE) cells of liver, spleen and bone marrow to bile pigments, mainly bilirubin (Fig. 21.10).

iv. About 6 g of Hb is broken down per day, from which about 250 mg of bilirubin is formed. From myoglobin and other heme containing proteins, another 50 mg of bilirubin is formed. Approximately 35 mg of bilirubin is formed from 1 g of Hb. A total of 300 mg of bilirubin is formed everyday; of which 80% is from destruction of old RBCs, 10% from ineffective erythropoiesis and the rest 10% from degradation of myoglobin and other heme containing proteins.

v. Microsomal Heme Oxygenase System:

Heme is degraded primarily by a microsomal enzyme system; heme oxygenase. It requires molecular oxygen and NADPH; for the regeneration of NADPH cytochrome c is required. The enzyme is induced by heme. The oxygenase enzyme specifically catalyzes the cleavage of the alpha methenyl bridge, which is linking the pyrrole rings I and II. The alpha methenyl bridge is quantitatively liberated as carbon monoxide (Fig. 21.11).

vi. The Fe++ liberated is oxidized to Fe+++ and taken up by transferrin.

vii. The linear tetrapyrrole formed is biliverdin which is green in color. In mammals it is further reduced to bilirubin, a red-yellow pigment, by an NADPH dependent biliverdin reductase (Fig. 21.11). But birds, amphibians and rabbits excrete the green biliverdin itself.

2. Transport to Liver

i. The liver plays the central role in the further disposal of the bilirubin (Figs 21.12 and 21.13). The bilirubin formed in the reticuloendothelial cells is insoluble in water. The lipophilic bilirubin is therefore transported in plasma bound to albumin.

ii. One molecule of albumin can bind 2 molecules of bilirubin. 100 ml of plasma can transport upto 25 mg of bilirubin.

iii. Albumin binds bilirubin in loose combination. So when present in excess, bilirubin can easily dissociate from albumin. The binding sites for bilirubin on albumin can be occupied by aspirin, penicillin, etc. Such drugs can, therefore, displace bilirubin from albumin. Hence, care should be taken while administering such drugs to newborn babies to avoid kernicterus.
iv. When the albumin–bilirubin complex reaches the sinusoidal surface of the liver, the bilirubin is taken up. The uptake is a carrier mediated active process.

3. Conjugation in Liver
   i. Inside the liver cell, the bilirubin is conjugated with glucuronic acid, to make it water soluble (Fig. 21.12). The first carbon of glucuronic acid is combined with the carboxyl group of the propionic acid side chains of the bilirubin molecule. About 80% molecules are in the diglucuronide form, while 20% are monoglucuronides.
   ii. Drugs like primaquine, novobiocin, chloramphenicol, androgens and pregnanediol may interfere in this conjugation process and may cause jaundice.

4. Excretion of Bilirubin to Bile
   The water soluble conjugated bilirubin is excreted into the bile by an active process and this occurs against a concentration gradient. This is the rate-limiting step in the catabolism of heme. It is induced by phenobarbitone. Excretion of conjugated bilirubin into bile is mediated by an ATP binding cassette protein which is called Multispecific organic anion transporter (MOAT), located in the plasma membrane of the biliary canaliculi. This protein is very similar to the Multidrug resistance like protein (MRP-2)

5. Fate of Conjugated Bilirubin in Intestine
   i. The conjugated bilirubin reaches the intestine through the bile. Intestinal bacteria deconjugate the conjugated bilirubin.
   ii. This free bilirubin (36 hydrogen atoms) is further reduced to a colorless tetapyrrole urobilinogen (UBG) (44 hydrogen) (Fig. 21.13).
   iii. Further reduction of the vinyl substituent groups of UBG leads to formation of mesobilinogen and stercobilinogen (SBG) (48 hydrogen). The SBG is mostly excreted through feces (250-300 mg/day) (Fig. 21.13).

6. Enterohepatic Circulation
   20% of the UBG is reabsorbed from the intestine and returned to the liver by portal blood. The UBG is again re-excreted (enterohepatic circulation) (Fig. 21.13). Since the UBG is passed through blood, a small fraction is excreted in urine (less than 4 mg/day).

7. Final Excretion
   i. UBG and SBG are both colorless compounds but are oxidized to colored products, urobilin (42 hydrogen) or stercobilin (46 hydrogen) respectively by atmospheric oxidation (See Table 21.8).
   ii. Both urobilin and stercobilin are present in urine as well as in feces. The normal color of feces is due to these compounds.
   iii. Black color is seen in constipation. If intestinal flora is decreased by prolonged administration of antibiotics, bilirubin is not reduced to bilinogens, and in the large gut, it is re-oxidized by O₂ to form biliverdin. Then green tinged feces is seen, especially in children.

Plasma Bilirubin
   i. Normal plasma bilirubin level ranges from 0.2–0.8 mg/dl. The unconjugated bilirubin is about
0.2–0.6 mg/dl, while conjugated bilirubin is only 0–0.2 mg/dl.

ii. If the plasma bilirubin level exceeds 1 mg/dl, the condition is called **hyperbilirubinemia**. Levels between 1 and 2 mg/dl are indicative of **latent jaundice**.

iii. When the bilirubin level exceeds 2 mg/dl, it diffuses into tissues producing yellowish discoloration of sclera, conjunctiva, skin and mucous membrane resulting in **jaundice**. Icterus is the Greek term for jaundice.

### van den Bergh Test for Bilirubin

Properties of bilirubin are shown in Table 21.9. Bilirubin reacts with *diazo reagent* (diazotized sulphanilic acid) to produce colored azo pigment. At pH 5, the pigment is purple in color. Conjugated bilirubin, being water soluble gives the color immediately; hence called **direct reaction**. Free bilirubin is water insoluble. It has to be extracted first with alcohol, when the reaction becomes positive; hence called **indirect reaction**.

### Tests for Bile Pigments

Bilinogens (UBG and SBG) react with *Ehrlich's aldehyde reagent* (para dimethyl amino benzaldehyde) to form red color. Oxidizing agents readily oxidize bilirubin to biliverdin to form a green color. In *Fouchet's test*, urine is heated with barium sulphate which adsorbs bilirubin. Ferric chloride oxidizes bilirubin to produce a green color. In *Gmelin's test*, nitric acid is used as the oxidizing agent. The bilinogens (UB and SB) form complexes with zinc ions which exhibit brilliant green fluorescence. This is the basis for *Schlesinger's reaction*. It is negative in normal urine. These findings are summarized in Table 21.10.

### HYPERBILIRUBINEMIAS

Depending on the nature of the bilirubin elevated, the condition may be grouped into conjugated or unconjugated hyperbilirubinemia. Based on the cause it may also be classified into congenital and acquired.

1. **Congenital Hyperbilirubinemias**

   They result from abnormal uptake, conjugation or excretion of bilirubin due to inherited defects.

1-A. **Crigler-Najjar Syndrome**

   Here the defect is in **conjugation**. In Type 1 (Congenital non-hemolytic jaundice), there is severe deficiency of *UDP glucuronyl transferase*. The disease is often fatal and the children die before the age of 2. Jaundice usually appears within the first 24 hours of life. Unconjugated bilirubin level increases to more than 20 mg/dl, and hence **kernicterus** results.

   The Type 2 disease is a milder form; only the second stage of conjugation is deficient. When barbiturates are given, some response
is seen and jaundice improves. Bilirubin level in blood exceeds 20 mg/dl in Crigler-Najjar syndrome Type 1 and does not exceed 20 mg/dl in Crigler-Najjar syndrome Type 2.

The gene encoding bilirubin-UDP glucuronyl transferase is a part of large gene complex present in chromosome number 2. This contains 13 substrate-specific exons, each with its own promoter. Exon A1 is involved with conjugation of bilirubin.

1-B. Gilbert’s Disease
It is inherited as an autosomal dominant trait. The defect is in the **uptake of bilirubin** by the liver. Bilirubin level is usually around 3 mg/dl, and patient is asymptomatic, except for the presence of mild jaundice.

1-C. Dubin-Johnson Syndrome
It is an autosomal **recessive** trait leading to defective excretion of conjugated bilirubin; so conjugated bilirubin in blood is increased. The disease results from the defective ATP-dependent organic **anion transport** in bile canaliculi. There is a mutation in the MRP-2 protein which is responsible for transport of conjugated bilirubin into bile. The bilirubin gets deposited in the liver and the liver appears black. The condition is referred to as **Black liver jaundice**.

In normal persons, when 250 mg BSP (Brom sulphathalain) is given intravenously, blood contains only 5% of original value at 45 minutes, and only 2% at 2 hr. BSP is taken up by hepatocytes, conjugated and then excreted through liver. In **Dubin-Johnson’s syndrome**, the BSP level in serum at 2 hours is more than the value at 45 min. This is because by 45 min, BSP is taken by hepatocytes, and hence blood level is reduced. But excretory defect for conjugated BSP leads to regurgitation into plasma. Hence higher value at 2 hr.

1-D. Rotor Syndrome
It is a similar condition, but the exact defect is not identified. Bilirubin excretion is defective, but there is no staining of the liver. It is an autosomal recessive condition.

2. Acquired Hyperbilirubinemias

2-A. Physiological Jaundice
It is also called as neonatal hyperbilirubinemia. In all newborn infants after the 2nd day of life, mild jaundice appears. This transient hyperbilirubinemia is due to an accelerated rate of destruction of RBCs and also because of the immature hepatic system of conjugation of bilirubin. In such cases, bilirubin does not increase above 5 mg/dl. It disappears by the second week of life.

2-B. Breast milk jaundice
In some breast-fed infants, prolongation of the jaundice has been attributed to high level of an estrogen derivative in maternal blood, which is excreted through the milk. This would inhibit the glucuronyl transferase system. Sulpha and such other drugs may release bilirubin from albumin, and may cause jaundice in newborn.

3. Hemolytic Jaundice

3-A. Hemolytic Disease of the Newborn

i. This condition results from incompatibility between maternal and fetal blood groups. Rh +ve fetus may produce antibodies in Rh -ve mother. In **Rh incompatibility**, the first child often escapes. But in the second pregnancy, the Rh antibodies will pass from mother to the fetus. They would start destroying the fetal red cells even before birth.

ii. Sometimes the child is born with severe hemolytic disease, often referred to as **erythroblastosis fetalis**.

iii. When blood level is more than 20 mg/dl, the capacity of albumin to bind bilirubin is exceeded. In young children before the age of 1 year, the blood-brain barrier is not fully matured, and therefore free bilirubin enters the brain (**Kernicterus**). It is deposited in brain, leading to mental retardation, fits, toxic encephalitis and spasticity.

Normal values: unconjugated (free) (indirect) bilirubin 0.2–0.7 mg/dl and conjugated (direct) bilirubin 0.1–0.4 mg/dl. A rise in serum bilirubin above 1 mg/dl is abnormal (latent jaundice); but jaundice appears only if the level goes above 2 mg/dl.
iv. If the child develops hemolytic disease, child may be given exchange transfusion along with phototherapy and barbiturates. Phototherapy with blue light (440 nm wave length) isomerizes the insoluble bilirubin to more soluble isomers. These can be excreted through urine without conjugation.

3-B. Hemolytic Diseases of Adults
This condition is seen in increased rate of hemolysis. It usually occurs in adults. The characteristic features are increase in unconjugated bilirubin in blood, absence of bilirubinuria and excessive excretion of UBG in urine and SBG in feces (Table 21.10). Common causes are:
   i. Congenital spherocytosis
   ii. GPD deficiency
   iii. Autoimmune hemolytic anemias
   iv. Toxins like carbon tetrachloride.

4. Hepatocellular Jaundice
The most common cause is viral hepatitis, caused by Hepatitis Viruses A, B, C, D or E. In pure hepatocellular disease, conjugation in liver is decreased and hence free bilirubin is increased in circulation. However, inflammatory edema of cell often compresses intracellular canaliculi at the site of bile formation and this produces an element of obstruction. When conjugated bilirubin level also increases, mixed type of jaundice results. Bilirubinuria also occurs. The UBG level in urine may be normal or decreased in hepatocellular jaundice (Table 21.11).

5. Obstructive Jaundice
Conjugated bilirubin is increased in blood, and it is excreted in urine. If there is complete obstruction, UBG will be decreased in urine or even absent (Fig. 21.13 and Table 21.11). In total obstruction of biliary tree, the bile does not enter the intestine. Since no pigments are entering into the gut, the feces become clay colored. The common causes of obstructive jaundice are:
   a. Intrahepatic cholestasis. This may be due to
      a-i. Chronic active hepatitis
      a-ii. Biliary cirrhosis
      a-iii. Lymphomas
      a-iv. Primary hepatoma
      a-v. Obstructive stage of viral hepatitis
   b. Extrahepatic obstruction. This may be due to
      b-i. Stones in the gall bladder or biliary tract
      b-ii. Carcinoma of head of pancreas
      b-iii. Enlarged lymph glands in the porta hepatis. More details on different types of jaundice are given in Chapter 26.
CHAPTER 22

Hemoglobin
(Structure, Oxygen and Carbon Dioxide Transport, Abnormal Hemoglobins)

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Structure of hemoglobin
2. Oxygen dissociation curve
3. Transport of carbon dioxide
4. Fetal hemoglobin
5. Carboxy hemoglobin
6. Met-hemoglobin
7. Hemoglobinopathies
8. Sickle cell anemia
9. Thalassemias
10. Myoglobin
11. Anemias

Marcello Malpighi described the RBCs in 1665. Felix Hoppe-Seyler in 1862 isolated pure hemoglobin. Christian Bohr in 1904 discovered that hemoglobin is the transporter of oxygen. In 1912 Kuster established the structure of hemoglobin. Hans Fischer synthesized heme in laboratory in 1920 (Nobel prize, 1930). Perutz (Nobel prize, 1962) studied the three dimensional structure of hemoglobin.

STRUCTURE OF HEMOGLOBIN
i. Normal level of Hemoglobin (Hb) in blood in males is 14-16 g/dl and in females, 13-15 g/dl. Hb is globular in shape. The adult Hb (HbA) has 2 alpha chains and 2 beta chains. Molecular weight of HbA is 67,000 Daltons (66,684 to be exact).

ii. Hb F (fetal Hb) is made up of 2 alpha and 2 gamma chains. Hb A2 has 2 alpha and 2 delta chains. Normal adult blood contains 97% HbA, about 2% HbA2 and about 1% HbF.

iii. Alpha chain gene is on chromosome 16 while the beta, gamma and delta chains are on chromosome 11.

iv. Each alpha chain has 141 amino acids. The beta, gamma and delta chains have 146 amino acids. The N-terminal and C-terminal end amino acids are shown in Table 22.1.

v. There are 36 histidine residues in Hb molecule; these are important in buffering action. The 58th residue in alpha chain is called distal histidine, because it is far away from the iron atom. The 87th residue in alpha chain is called proximal histidine, because it lies near to the iron atom (Fig. 22.1).

Box 22.1. Oxygenation and Oxidation

When hemoglobin carries oxygen, the Hb is oxygenated. The iron atom in Hb is still in the ferrous state. Oxidized Hemoglobin is called Met-Hb; then iron is in ferric state and the oxygen carrying capacity is lost.
vi. The alpha and beta subunits are connected by relatively weak non-covalent bonds like van der Waals forces, hydrogen bonds and electrostatic forces.

Attachment of Heme with Globin Chain
i. There are 4 heme residues per Hb molecule, one for each subunit in Hb. The 4 heme groups account for about 4% of the whole mass of Hb. The heme is located in a hydrophobic cleft of globin chain (Fig. 22.1).

ii. The iron atom of heme occupies the central position of the porphyrin ring. The reduced state is called ferrous (Fe++) and the oxidized state is ferric (Fe+++). The ferrous iron has 6 valencies and ferric has 5 valencies. In hemoglobin, iron remains in the ferrous state (Box 22.1).

iii. Iron carries oxygen: The iron is linked to the pyrrole nitrogen by 4 coordinate valency bonds and a fifth one to the imidazole nitrogen of the proximal histidine (Fig. 22.1). In oxy-Hb, the 6th valency of iron binds the O₂. The oxygen atom directly binds to Fe, and forms a hydrogen bond with an imidazole nitrogen of the distal histidine. In deoxy-Hb, a water molecule is present between the iron and distal histidine (Fig. 22.1). As the porphyrin molecule is in resonance, central iron atom is linked by coordinate bond. The distal histidine lies on the side of the heme ring (Fig. 22.1).

The nonpolar vinyl groups of the heme are buried deep in the hydrophobic interior of globin chain. The charged or polar substituent groups of the porphyrin are oriented towards the hydrophilic outer surface of the subunit. The propionic acid residues of the porphyrin ring form electrostatic bonds with two separate arginine residues of the globin (Fig. 22.1). In a deoxy hemoglobin molecule, iron atoms between alpha and beta chains are 25 Å apart, and between 2 beta chains are 33.4 Å apart (1 Å = 0.1 nm). When oxygenation occurs, the iron moves to 0.1 Å of the plane of the heme ring.

Discovery of carbon dioxide was made by Joseph Black in 1757 and that of oxygen by Priestley in 1771. In 1775, Lavoisier showed that interchange of oxygen is taking place in lungs. In 1837, Theodor Bischoff showed the presence of carbon dioxide and oxygen in blood. The effect of carbon dioxide on respiration was studied by Haldane in 1905, and that of pH by Hasselbalch in 1912. In 1925, blood gas analysis was done by Donald van Slyke.

TRANSPORT OF OXYGEN BY HEMOGLOBIN
Hemoglobin has all the requirements of an ideal respiratory pigment (Barcroft):

**Fig. 22.2.** Diagrammatic representation of the subunit interaction in hemoglobin. Pink rectangles represent Hb monomers. Black connection lines represent salt bridges. As oxygen is added, salt bridges are successively broken and finally 2,3-BPG is expelled. Simultaneously the T (taught) confirmation of deoxy-Hb is changed into R(relaxed) confirmation of oxy-Hb. Blue circle represents 2,3-bisphosphoglycerate (BPG).
So physiologically, 40% of oxygen is released (Fig. 22.3C).

v. The pO₂ in inspired air is 158 mm Hg; in alveolar air 100 mm Hg; in the blood in lungs, pO₂ is 90 mm Hg; and in capillary bed, it is 40 mm Hg. In tissues, oxygen is liberated from hemoglobin. In lung capillaries, oxygen is taken up by the hemoglobin. Oxygen carriage of hemoglobin is schematically depicted in Figure 22.4. The following factors will affect the oxygen dissociation curve:

1. Heme-heme Interaction and Cooperativity
   i. The sigmoid shape of the oxygen dissociation curve (ODC) is due to the allosteric effect, or cooperativity. The equilibrium of Hb with oxygen is expressed by the Hill equation (AV Hill, Nobel prize, 1922).
   ii. The binding of oxygen to one heme residue increases the affinity of remaining heme residues for oxygen (homotropic interaction) (Fig. 22.3B). This is called positive cooperativity.

Oxygen Dissociation Curve (ODC)

i. The ability of hemoglobin to load and unload oxygen at physiological pO₂ (partial pressure of oxygen) is shown by the oxygen dissociation curve (ODC) (Fig. 22.3). Hemoglobin is oxygenated and not oxidized (Box 22.1).

ii. At the oxygen tension in the pulmonary alveoli, the Hb is 97% saturated with oxygen. Normal blood with 15 gm/dl of Hb can carry 1.34 x 15 = 20 ml of O₂/dl of blood.

iii. In the tissue capillaries, where the pO₂ is only 40 mm of Hg, theoretically, Hb saturation is 75%. Thus under NTP conditions, blood can release only 22% (Fig. 22.3A).

iv. But actually in tissue capillaries, where pO₂ is 40 mm of Hg, the Hb is about 60% saturated.

Fig. 22.3. Oxygen dissociation curve (ODC)

Fig. 22.4 In tissues oxy-Hb releases oxygen
**Chapter 22; Hemoglobin**

**Affinity**

1 time 2 times 4 times 18 times

Hb → HbO₂ → HbO₄ → HbO₆ → HbO₈

\(+\)O₂ \(+\)O₂ \(+\)O₂ \(+\)O₂

**iii.** Thus each successive addition of O₂ increases the affinity of Hb to oxygen synergistically.

**iv.** Similarly, binding of 2,3-BPG at a site other than the oxygen binding site, lowers the affinity for oxygen (heterotropic interaction).

**v.** The quaternary structure of oxy-Hb is described as R (relaxed) form; and that of deoxy-Hb is T (tight) form.

**vi.** When oxygenation occurs the salt bonds are broken successively. Thus, on oxygenation, the hemoglobin molecule can form two similar dimers.

\((2 \times \text{alpha}) + (2 \times \text{beta}) \rightarrow 2 \times (\text{alpha-beta})\)

\((\text{deoxy-Hb}) \rightarrow (\text{oxy-Hb})\)

**vii.** *Alteration of Structure:* The T conformation of deoxyhemoglobin is maintained by C-terminal arginine carboxyl group of alpha-1 with amino group of lysine (132nd residue) in alpha-2 and C-terminal arginine group of alpha-1 with carboxyl group of aspartic acid (131 residue) in alpha-2. These alpha-1 and alpha-2 bridges cannot be formed in oxyhemoglobin. During oxygen uptake, the T form switches to the R form with disruption of the salt bridges (Fig. 22.2). Hemoglobin subunits are moved relative to one another. During oxygenation, the alpha1-beta2 interface shows movement. The two subunits slip over each other. The binding of the iron to oxygen is now stronger. Hence the R form has a higher affinity for oxygen.

**2. Effect of pH and pCO₂**

**i.** When the pCO₂ is elevated, the H⁺ concentration increases and pH falls. In the tissues, the pCO₂ is high and pH is low due to the formation of metabolic acids like lactate. Then the affinity of hemoglobin for O₂ is decreased (the ODC is shifted to the right) and so, more O₂ is released to the tissues (R → T change takes place) (Fig. 22.3C).

**ii.** In the lungs, the opposite reaction is found, where the pCO₂ is low, pH is high and pO₂ is significantly elevated. More O₂ binds to hemoglobin and the ODC is shifted to the left. Moreover, T → R change is seen.

**3. The Bohr Effect**

**i.** The influence of pH and pCO₂ to facilitate oxygenation of Hb in the lungs and deoxy-

genation at the tissues is known as the Bohr effect (1904).

**ii.** Binding of CO₂ forces the release of O₂.

**iii.** When the pCO₂ is high, CO₂ diffuses into the red blood cells. The carbonic anhydrase in the red cells favors the formation of carbonic acid (H₂CO₃).

**Carbonic anhydrase**

\(\text{CO}_2 + \text{H}_2\text{O} \rightarrow \text{H}_2\text{CO}_3 \rightarrow \text{H}^+ + \text{HCO}_3^-\)

**iv.** When carbonic acid ionizes, the intracellular pH falls. The affinity of Hb for O₂ is decreased and O₂ is unloaded to the tissues.

**4. The Chloride Shift**

**i.** When CO₂ is taken up, the HCO₃⁻ concentration within the cell increases. This would diffuse out into the plasma. Simultaneously, chloride ions from the plasma would enter in the cell to establish electrical neutrality. This is called *chloride shift or Hamburger effect* (Fig. 22.5). Thus on venous side, RBCs are slightly bulged due to the higher chloride ion concentration.

**ii.** When the blood reaches the lungs, the reverse reaction takes place. The deoxyhemoglobin liberates protons. These would combine with HCO₃⁻ to form H₂CO₃ which is dissociated to CO₂ and H₂O by the carbonic anhydrase. The CO₂ is expelled. As HCO₃⁻ binds H⁺, more HCO₃⁻ from plasma enters the cell and Cl⁻ gets out (reversal of chloride shift) (See Figure 22.6).

**5. Effect of Temperature**

The term p50 means, the pO₂ at which Hb is half saturated (50%) with O₂. The p50 of normal Hb at

![Fig. 22.5. Chloride shift; reactions in tissues](image)
37°C is 26 mm Hg. Elevation of temperature from 20 to 37°C causes 88% increase in p50. Metabolic demand is low when there is relative hypothermia. Shift in ODC to left at low temperature results in release of less O2 to the tissues. On the other hand, under febrile conditions, the increased needs of O2 are met by a shift in ODC to right (Fig. 22.3D).

6. Effect of 2,3-BPG
   i. Normally the 2,3-bisphosphoglycerate level is 15 + 1.5 mg /g Hb. The 2,3-BPG concentration is higher in young children compared to the elderly.
   ii. The 2,3-BPG is produced from 1,3-BPG, an intermediate of glycolytic pathway (see Fig. 9.20).
   iii. The 2,3-BPG, preferentially binds to deoxy-Hb and stabilizes the T conformation. When the T form reverts to the R conformation, the 2,3-BPG is ejected. During oxygenation, BPG is released (Fig. 22.2).
   iv. The high oxygen affinity of fetal blood (HbF) is due to the inability of gamma chains to bind 2,3-BPG.

Adaptation to High Altitude
1. Increase in the number of RBCs
2. Increase in concentration of Hb inside RBCs
3. Increase in BPG.

Laboratory Diagnosis
When hemoglobin is examined spectroscopically, oxy-Hb has 2 absorption bands at 540 and 580 nm. When sodium hydrosulphite is added, de-oxygenation occurs, the color changes to purple, and the absorption spectrum has only a single broad band at 565 nm. On re-oxygenation by vigorous shaking of the test tube, the absorption spectrum changes to the original.

TRANSPORT OF CARBON DIOXIDE
At rest, about 200 ml of CO2 is produced per minute in tissues. The CO2 is carried by the following 3 ways.

1: Dissolved Form
About 10% of CO2 is transported as dissolved form.

\[
\text{CO}_2 + \text{H}_2\text{O} \rightarrow \text{H}_2\text{CO}_3 \rightarrow \text{HCO}_3^- + \text{H}^+ 
\]

The hydrogen ions thus generated, are buffered by the buffer systems of plasma.

2: Isohydric Transport of Carbon Dioxide
   i. Isohydric transport constitutes about 75% of CO2. It means that there is minimum change in pH during the transport. The H+ ions are buffered by the deoxy-Hb and this is called the Haldane effect.
   ii. In tissues: Inside tissues, pCO2 is high and carbonic acid is formed. It ionizes to H+ and \text{HCO}_3^- inside the RBCs. The H+ ions are buffered by deoxy-Hb and the \text{HCO}_3^- diffuses out into the plasma. In order to maintain ionic equilibrium, chloride ions are taken into RBC (chloride shift, Fig. 22.5). Thus the CO2 is transported from tissues to lungs, as plasma bicarbonate, without significant lowering of pH. The H+ are bound by N-terminal NH2 groups and also by the imidazole groups of histidine residues.
   iii. In the lungs:

\[
\text{H–Hb} + 4\text{O}_2 \rightarrow \text{Hb} (\text{O}_2)_4 + \text{H}^+ 
\]

Fig. 22.6. Chloride shift; reactions in lungs
iv. The protons released in the RBC combine with 
$\text{HCO}_3^-$ forming $\text{H}_2\text{CO}_3$ which would dissociate 
to $\text{CO}_2$, that is expelled through pulmonary 
capillaries.
v. As the $\text{HCO}_3^-$ level inside the erythrocyte falls, 
more and more $\text{HCO}_3^-$ gets into the RBC, and 
chloride diffuses out (reversal of chloride shift) 
(Fig. 22.6).

3: Carriage as Carbamino-Hemoglobin
The rest 15% of $\text{CO}_2$ is carried as carbamino-
hemoglobin, without much change in pH. A fraction 
of $\text{CO}_2$ that enters into the red cell is bound to Hb 
as a carbamino complex.

\[ \text{R–NH}_2 + \text{CO}_2 \rightarrow \text{R–NH–COOH} \]

The N-terminal amino group (valine) of each 
globin chain forms carbamino complex with carbon 
dioxide. Deoxy-hemoglobin binds $\text{CO}_2$ in this 
manner more readily than oxy-hemoglobin.

Clinical applications are shown in Box 22.2.

Fetal Hemoglobin (HbF)
1. HbF has 2 alpha chains and 2 gamma chains. 
   Gamma chain has 146 amino acids.
2. The differences in physicochemical properties 
   when compared with HbA are:
   a. Increased solubility of deoxy HbF
   b. Slower electrophoretic mobility for HbF

Box 22.2. Clinical Applications
1. In all hypoxic states, the $\text{O}_2$ affinity is decreased with 
a shift in ODC to the right and an increase in 2,3-
BPG inside RBC. The adaptation to the high altitude 
where $\text{pO}_2$ is low, includes increased pulmonary 
ventilation, polycythemia and increase in 2,3-BPG 
level with a shift in ODC to right.
2. In anemia, where the total concentration of Hb 
is reduced, increased oxygen unloading alone will 
ensure proper oxygenation of tissues.
3. In many cases 2,3-BPG level varies inversely as the 
   hemoglobin concentration.
4. In chronic pulmonary diseases and cyanotic cardiac 
diseases also the 2,3-BPG level is increased ensuring 
maximum unloading of $\text{O}_2$ to tissues.
5. The red cell 2,3-BPG level is decreased in acidosis 
   and increased in alkalosis. Hence, the expected 
shift in ODC to the right or left is not observed.
6. Transfusion of large volumes of stored blood, which 
   has a low level of 2,3-BPG can lead to sudden 
   hypoxia, since it can cause a left-shifted ODC.

Hemoglobin A₂
It is a normal adult hemoglobin; it is about 2% of 
total Hb. It has 2 alpha chains and 2 delta chains. 
The delta chain has sequence homology with beta 
chain. In beta thalassemia, as a compensation, 
HbA₂ is increased. The iso-electric pH of HbA₂ is 
7.4, while HbA has the pI value of 6.85. So, HbA₂ is 
slower moving on electrophoresis.

Embryonic Hemoglobins
Several hemoglobins are found during fetal life, but absent in 
adult life. Examples are Hb Gover-1 (2 zeta and 2 epsilon 
chains); Gover-2 (2 alpha chains and 2 epsilon chains); Hb 
Portland (2 gamma and 2 delta chains). Embryonic 
hemoglobins are produced from 3rd to 8th weeks of gestation, 
when the site of erythropoiesis is in liver.

HEMOGLOBIN DERIVATIVES
Hemoglobin derivatives are formed by the combi-
nation of different ligands with the heme part, or 
change in the oxidation state of iron. Oxy-Hb is 
dark red, deoxy-Hb is purple, met-Hb is dark 
brown, CO-Hb is cherry red and sulph-Hb is green 
in color. Normally concentration of deoxy-Hb is less 
than 5% of the total Hb. If the level increases 
cyanosis occurs.

1. Carboxy-Hemoglobin (Carbon Monoxyl Hb) 
   (CO-Hb)
   i. Hemoglobin binds with carbon monoxide (CO) 
to form carboxy-Hb. The affinity of CO to Hb 
is 200 times more than that of oxygen. It is 
then unsuitable for oxygen transport.
ii. When one molecule of CO binds to one monomer of the hemoglobin molecule, it increases the affinity of others to O₂; so that the O₂ bound to these monomers are not released. This would further decrease the availability of oxygen to the tissues.

iii. **Carbon Monoxide Poisoning:** CO is a colorless, odorless, tasteless gas generated by incomplete combustion. CO poisoning is a major occupational hazard for workers in mines. Breathing the automobile exhaust in closed space is the commonest cause for CO poisoning. The carboxy-Hb level in normal people is 0.16%. An average smoker has an additional 4% of CO-Hb. One cigarette liberates 10–20 ml carbon monoxide into the lungs.

iv. **Clinical Manifestations:** Clinical symptoms manifest when carboxy-Hb levels exceed 20%. Symptoms are breathlessness, headache, nausea, vomiting, and pain in chest. At 40-60% saturation, death can result.

v. Administration of O₂ is the treatment. In severe cases, oxygen under high pressure (hyperbaric oxygen) is helpful.

vi. The absorption bands of carboxy-Hb is similar to that of oxy-Hb. But on adding a reducing agent like sodium dithionite, it fails to convert carboxy-Hb to deoxy-Hb; whereas oxy-Hb is converted.

2-A. **Methemoglobin (Met-Hb)**
   i. When the ferrous (Fe⁺⁺) iron is oxidized to ferric (Fe⁺⁺⁺) state, met-Hb is formed.
   ii. Small quantities of met-Hb formed in the RBCs are readily reduced back to the ferrous state by met-Hb reductase enzyme systems. About 75% of the reducing activity is due to enzyme system using NADH and cytochrome b₅ (Fig. 22.7).
   iii. Another 20% of the reducing activity is due to NADPH dependent system.

   iv. **Glutathione** dependent Met-Hb-reductase accounts for the rest 5% activity.

2-B. **Methemoglobinemias**
   Normal blood has only less than 1% of methemoglobin. It has markedly decreased capacity for oxygen binding and transport. An increase in methemoglobin in blood, (methemoglobinemia) is manifested as cyanosis. Causes may be congenital or acquired.

2-C. **Congenital Methemoglobinemia**
   Presence of Hb variants like HbM can cause congenital methemoglobinemia. Cytochrome b₅ reductase deficiency is characterized by cyanosis from birth. 10-15% of hemoglobin may exist as methemoglobin. Oral administration of methylene blue, 100-300 mg/day or ascorbic acid 200-500 mg/day decreases met-Hb level to 5-10% and reverses the cyanosis.

2-D. **Acquired or Toxic Methemoglobinemia**
   i. Met-hemoglobinemia may develop by intake of water containing nitrates or due to absorption of aniline dyes. Aniline dye workers have been known to develop met-hemoglobinemia.
   ii. Drugs which produce met-hemoglobinemia are: acetaminophen, phenacetin, sulphanilamide, amyl nitrite, and sodium nitroprusside.
   iii. **Glucose-6-phosphate dehydrogenase deficiency:** In persons with this enzyme deficiency, the condition may be manifested even with small doses of drugs. In such persons, NADPH is not available in the RBC. Therefore in such individuals, disease is manifested easily (see Chapter 23). In such patients, intravenous leukomethylene blue 2 mg/kg is effective, which will substitute for the NADPH.

2-E. **Laboratory analysis**
   Ferricyanide can oxidize oxy- or deoxy-Hb to met-Hb. The color changes to dark brown and absorption spectra show a band in the red with its center at 633 nm, while the bands for Oxy-Hb persist. Sodium hydrosulfite or dithionite reconverts met-Hb to oxy-Hb.

2-F. **Hemin Crystals**
   When iron is oxidized to Fe⁺⁺⁺, it has a net positive charge. It can combine with negatively charged chloride, to form hemin or hematin chloride. Hemin
crystals can be prepared from even very old blood stains in medicolegal cases. Blood or eluted blood stains are heated with Nippe’s fluid (1% solution of KCl, KBr and KI in glacial acetic acid) over a glass slide, when dark brown rhombic crystals are seen under the microscope. The test is sensitive, but is answered by the heme part of blood of all species.

3. Sulf-hemoglobinemia
When hydrogen sulfide acts on oxy-hemoglobin, sulf-hemoglobin is produced. It can occur in people taking drugs like sulphonamides, phenacetin, acetanilide, dapsone, etc. It cannot be converted back to oxy-hemoglobin. It is seen as basophilic stippling of RBC, throughout its lifespan.

4. Nitric Oxide
Hemoglobin binds nitric oxide (NO) with high affinity similar to binding of carbon monoxide (CO). The NO is delivered at its site of action, i.e. capillary endothelium. The positive co-operative effect and effect of H⁺ also play a role in the binding and delivery of NO. Binding of NO by hemoglobin increases its half-life. The heme iron preferentially binds NO in the T conformation. When hemoglobin acquires the R conformation, the NO is transferred to a cysteinyl SH group on the beta chain and then to the SH group of a small molecule like GSH, when R form reverts to T state. The X-S-NO complex is biologically very potent and even under low oxygen tension delivers NO to tissue capillaries.

5. Glycated Hemoglobin
Described in detail in Chapter 24.

HEMOGLOBIN (GLOBIN CHAIN) VARIANTS
In humans, alpha chain genes are located on chromosome No. 16 and beta type genes are clustered in chromosome No. 11.

Hemoglobinopathies
Hundreds of hemoglobin variants leading to hemoglobinopathies have been discovered (Box 22.3). The variants may be either alpha chain variants or beta chain variants. In addition, although rare, gamma and delta chain variants have also been described (see Table 22.2).

The hemoglobin variants may be classified into 5 major types, based on their clinical manifestations.
Box 22.3. Hemoglobinopathy and Thalassemia

Abnormalities in the primary sequence of globin chains lead to **hemoglobinopathies**, e.g. HbS. Abnormalities in the rate of synthesis would result in **thalassemias**. In other words, normal globin chains in abnormal concentrations result in thalassemias, e.g. beta thalassemia.

1. Sickle syndromes
   A. Sickle-cell trait (AS)
   B. Sickle-cell disease with SS, SC, SD, SO varieties and S beta thalassemia

2. Unstable hemoglobins
   Congenital Heinz body anemia; Hb Zurich. Unstable Hb variants have an increased tendency to denature and hence tend to form molecular aggregates within cells which lead to increased hemolysis. Heinz bodies are stained purple with cresyl violet. Their occurrence in RBC indicates that the cells have been subjected to oxidative stress. The membrane bound Heinz bodies alter the surface of the red cells, creating indentations. As a result, they have a tendency of getting trapped in the spleen. So, lifespan of the RBC is reduced. Patients will have moderate to severe anemia.

3. Hemoglobins with abnormal oxygen affinity
   A. High affinity—Polycythemia (familial): Hb Chesapeake. Hb binds oxygen, but has difficulty in unloading. The ODC is shifted to the left, with a diminished Bohr effect. So, tissues suffer from hypoxia.
   B. Low affinity—Cyanosis (familial): HbM.

4. Structural variations leading to thalassemia
   A. Alpha thalassemia—Hb Constant spring, delta beta thalassemia, Hb Lepore
   B. Beta thalassemia: Hb Quong sze

5. Non-symptomatic hemoglobin variants
   HbP, Q, N, J, etc.

1. Hemoglobin S (HbS)
   **(Sickle Cell Hemoglobin)**
   Of the hemoglobin variants, HbS constitutes the most common variety worldwide. In 1949 Linus Pauling (Nobel prize, 1954) established that a hemoglobin with abnormal electrophoretic mobility is responsible for the sickling disease.

1-A. Sickle Cell Disease
   i. The glutamic acid in the 6th position of beta chain of HbA is changed to valine in HbS. This single amino acid substitution leads to polymerization of hemoglobin molecules inside RBCs. This causes a distortion of cell into sickle shape (Fig. 22.8).

   ii. The substitution of hydrophilic glutamic acid by hydrophobic valine causes a localized stickiness on the surface of the molecule (see Fig. 22.9). The deoxygenated HbS may be depicted with a protrusion on one side and a cavity on the other side, so that many molecules can adhere and polymerize.

   iii. HbA and HbF will prevent sickling, because they do not co-polymerize with HbS. HbS can bind and transport oxygen. The sickling occurs under deoxygenated state.

   iv. The sickled cells form small plugs in capillaries. Occlusion of major vessels can lead to infarction in organs like spleen. Death usually occurs in the second decade of life.

   v. The heterozygous state is very common in Central and West Africa as well as in East and Central parts of India. Tribals all over India show an increased incidence of SS and AS. The slave trade has played an important role in spreading the gene from Africa to different parts of America.

1-B. Sickle Cell Trait
   i. In heterozygous (AS) condition, 50% of Hb in the RBC is normal. Therefore the sickle cell trait as such does not produce clinical symptoms. Such persons can have a normal lifespan.

   ii. At higher altitudes, hypoxia may cause manifestation of the disease. Chronic lung disorders may also produce hypoxia-induced sickling in HbS trait.

   iii. In the electrophoresis, the abnormal HbS can be detected along with normal Hb in persons with HbS trait (Fig. 22.11).

   iv. HbS gives protection against malaria:
   The high incidence of the sickle cell gene in
population coincides with the area endemic for malaria. HbS affords protection against *Plasmodium falciparum* infection (Fig. 22.10). Hence the abnormal gene was found to offer a biologic advantage.

1-C. Electrophoresis
Electrophoresis at alkaline pH shows a slower moving band than HbA. At pH 8.6, carboxyl group of glutamic acid is negatively charged. Lack of this charge on HbS makes it less negatively charged, and decreases the electrophoretic mobility towards positive pole (Fig. 22.11). At acidic pH, HbS moves faster than HbA. In sickle cell trait, both the bands of HbA and HbS can be noticed (Fig. 22.11).

1-D. Sickling Test
A blood smear is prepared. A reducing agent such as sodium dithionite is added. Blood smear examined under the microscope shows sickled RBCs (Fig. 22.8).

1-E. Management of Sickle Cell Disease
Repeated blood transfusions may be required in severe anemia. But this can lead to iron overload and cirrhosis. Treatment with anti-sickling agents like hydroxyurea, cyanate and aspirin, that interfere with polymerization are tried. Sodium butyrate will induce HbF production with clinical improvement.

2. Hemoglobin E
It is the second most prevalent hemoglobin variant. It is due to the replacement of beta 26 glutamic acid by Lysine (Table 22.2). It is primarily seen in orientals of South-East Asia (Thailand, Myanmar, Bangladesh, etc). The variant is very prevalent in West Bengal in India. Heterozygotes are completely asymptomatic. HbE has similar mobility as of A2 on electrophoresis.

3. Hemoglobin C
In normals, the 6th amino acid in beta chain is glutamic acid; it is replaced by lysine in HbC (Table 22.2). The presence of HbC is seen mostly in the black race. AC heterozygotes do not show any clinical manifestations. But those who are double heterozygous for Hbs and HbC (SC) have a moderate disease. Homozygotes (CC) have a mild to moderate hemolytic anemia. The HbC is slower moving than HbA on electrophoresis at alkaline pH.

4. Hemoglobin D
It does not produce sickling. HbD Punjab results from replacement of beta 121 glutamic acid by glutamine (HbD Punjab) (Table 22.2). HbD migrates similar to HbS on electrophoresis. HbD Punjab is the commonest Hb variant seen in Punjabi population.

5. M-Hemoglobins (Hb M)
These are a group of variants, where the substitution occurs in the proximal or distal histidine residues of alpha or beta chains.

   - Alpha 58 His → Tyr (Hb M Boston)
   - Beta 92 His → Tyr (Hb M Hyde Park)

As a result, the heme has a tendency to get oxidized to hemin, forming methemoglobin. Oxygen binding is decreased. This would result in cyanosis.

6. Inheritance of Hemoglobin Variants

   i. They are inherited as codominant/recessive traits. One beta chain gene is inherited from each parent. If both parents are heterozygous for S, (the abnormal gene), there is 50% chance that the child will be AS, 25% chance for AA and 25% chance for SS genotype (Inheritance is described in Chapter 42).

   ii. If the genotype is SS, all the Hb molecules produced are abnormal, and hence disease is manifested.

   iii. If one parent is heterozygous for HbS and another for C or beta thalassemia, 25% chances are that the child will be a double heterozygote (Fig. 22.12).

   iv. An individual inherits only 2 beta chain genes; but 4 alpha chain genes are inherited. So, the alpha chain variants constitute only 25% of the total hemoglobin in circulation and are less likely to produce impairment of red cell function (codominant inheritance). Thus beta chain disease is more common and more severe than alpha chain disease.

### THALASSEMIAS

i. The name is derived from the Greek word, “thalassa”, which means “sea”. Greeks identified this disease present around Mediterranean sea.
Thalassemia may be defined as the normal globin chains in abnormal proportions (Box 22.3). The gene function is abnormal, but there is no abnormality in the polypeptide chains.

Reduction in alpha chain synthesis is called alpha thalassemia, while deficient beta chain synthesis is the beta thalassemia. Other types like delta-beta thalassemia, Hb Lepore, hereditary persistence of HbF (HPF) are related conditions.

1-A. Beta thalassemia
Beta thalassemia is more common than alpha variety. Beta type is characterized by a decrease or absence of synthesis of beta chains. As a compensation, gamma or delta chain synthesis is increased.

1-B. Inheritance
Beta thalassemias are phenotypically described as beta (+) or beta (o) depending on whether there is beta chain synthesis or not. Beta (o) thalassemia may result from base substitutions. Beta (+) thalassemias are produced from defects in post-transcriptional processing of mRNA.

2. Alpha thalassemias
They may result from different types of gene deletions. Since there are 2 pairs of alpha genes per cell, a single gene deletion in one chromosome or a pair of genes in the chromosomes does not have much effect on a chain production. Alpha thalassemia is rarer because alpha chain deficiency is incompatible with life.

3. Thalassemia Syndromes
i. These syndromes are mainly seen in people of Asian, African and Mediterranean origin. All cases of thalassemias are characterized by deficiency of HbA synthesis.
ii. Hypochromic microcytic anemia.
iii. In homozygous state, clinical manifestations are severe, and hence called Thalassemia major.
   There will be nucleated RBCs in peripheral circulation (Fig. 22.13).
iv. In heterozygous conditions, the clinical signs and symptoms are minimal; they are called Thalassemia minor.
v. The synthesis of unaffected chains occurs at the normal rate. Since they do not have complementary chains to bind, they form aggregates and precipitate within the cell. These precipitates or inclusion bodies lead to membrane damage and destruction of red cells.

vi. The co-existence of HbS and beta thalassemia trait is fairly common.

vii. Homozygous beta thalassemia is characterized by severe anemia, hypersplenism and
hepatosplenomegaly. The marrow in the skull bones expand producing the "hair-on-end appearance" described in X-ray.

viii. Repeated transfusion is the only available treatment. This may lead to iron overload. Splenectomy may also lessen the anemia. Marrow transplantation has been successfully tried in a few cases.

4. Hemoglobin Lepore
It is composed of 2 alpha chains and 2 delta-beta chimeric chains. The N-terminal made up of delta chain and C-terminal is made of beta chain. Nonhomologous crossing over of the chromosomes is the cause for this chimera.

MYOGLOBIN (Mb)
i. It is seen in muscles. Myoglobin content of skeletal muscle is 2.5 g/100 g; of cardiac muscle is 1.4 g% and of smooth muscles 0.3 g%.

ii. Mb is a single polypeptide chain (Fig. 22.14). Human Mb contains 152 amino acids with a molecular weight of 17,500 Daltons.

iii. One molecule of Mb can combine with 1 molecule of oxygen. The Hb carries oxygen from lungs to tissue capillaries, from where oxygen diffuses into tissues. In the muscles, the oxygen is taken up by Mb for the sake of tissue respiration.

iv. Mb has higher affinity for oxygen than that of Hb. The pO$_2$ in tissue is about 30 mm of Hg, when Mb is 90% saturated. At this pO$_2$, Hb saturation will be only 50%.

v. In severe physical exercise, pO$_2$ in muscles lowers to 5 mm Hg, when myoglobin releases all the bound oxygen.

vi. Mb has a high oxygen affinity while Bohr effect, co-operative effect and 2,3-BPG effect are absent.

Myoglobin in Urine and Blood
Severe crush injury causes release of myoglobin from the damaged muscles. Being a small molecular weight protein, Mb is excreted through urine (myoglobinuria). Urine color becomes dark red.

Myoglobin will be released from myocardium during myocardial infarction (MI), and is seen in serum. Serum myoglobin estimation is useful in early detection of myocardial infarction (Chapter 23).

ANEMIAS
In India, anemia is the most common medical problem. Perhaps about 75% of patients attending a primary health center may have signs and symptoms directly or indirectly related to anemia. Anemia results when the Hb concentration in blood is reduced. Normal value for Hb in normal male is 14 to 16 g/dl and in female 13 to 15 g/dl. If the Hb level is below 10 g/dl, it is a severe condition.

The most common cause for anemia in India, is iron deficiency which is described in Chapter 35. A list of other causes is given in Box 22.4.
Clinical Enzymology and Biomarkers

Cardiac Biomarkers

A biomarker is a clinical laboratory test which is useful in detecting dysfunction of an organ. Cardiac biomarkers are used to detect cardiac diseases, which may be
a. Acute coronary syndrome resulting from myocardial ischemia
b. Congestive cardiac failure due to ventricular dysfunction (Box 23.1). The different markers are used to:
   i. Detect myocardial ischemia at the earliest
   ii. Monitoring the progression of the condition
   iii. To predict the risk in cardiac dysfunction.

Commonly used biomarkers for early detection of acute myocardial infarction are:
1. Cardiac troponins, TnI and TnT
2. Creatine kinase, CK-MB
3. Myoglobin. Of these, troponins and CK-MB are the sensitive and specific markers, whereas myoglobin though sensitive, is non-specific (Other markers are listed in Box 23.2).

Predictors of risk in cardiac disease are of two types:
a. For predicting the onset of ischemia
b. Those which quantify the ventricular damage

The risk predictors mainly include the athero- genic lipoproteins in plasma along with the inflammatory marker like hsCRP (high sensitive C reactive protein). These are described in Chapter 25.

Box 23.2. Markers for Cardiac Diseases

Serial testing of the following cardiac enzymes is usually done to guide the prognosis (Box 23.1). No single marker can successfully identify or exclude acute MI within the first 6 hr.

i. Creatine kinase (CKMB)
ii. Cardiac troponin I (CTI) and Cardiac troponin T (CTT). These are not true enzymes
iii. Brain Natriuretic Peptide (BNP). It is a reliable marker of ventricular function
iv. LDH and AST were previously used as markers of myocardial infarction, but no more used in clinical practice.
CREATINE KINASE (CK)

1. Reference Values

It catalyzes the reaction shown in Figure 23.1. It was called as creatine phosphokinase in old literature. **Normal serum** value for CK is 15-100 U/L for males and 10-80 U/L for females.

2. CK and Heart Attack

i. CK value in serum is increased in myocardial infarction. The time course is shown in Figure 23.2 and Table 23.1. The CK level starts to rise within 3-6 hours of infarction.

ii. Therefore, CK estimation is very useful to detect early cases where ECG changes may be ambiguous. A second peak may indicate another ischemic episode.

iii. The CK level is not increased in hemolysis or in congestive cardiac failure; and therefore CK has an advantage over LDH. The area under the peak and slope of initial rise are proportional to the size of infarct.

3. Iso-enzymes of CK

i. CK is a dimer; each subunit has a molecular weight of 40 kD. The subunits are called B for brain and M for muscle. Therefore, three iso-enzymes are seen in circulation. See Table 23.2.

ii. Normally CK2 (heart iso-enzyme) is only 5% of the total activity. Even doubling of the value of CK2 (MB) iso-enzyme may not be detected, if total value of CK alone is estimated. Hence, the estimation of MB-isoenzyme is the best diagnostic marker in myocardial infarction.

4. CK and Muscle Diseases

i. The level of CK in serum is very much elevated in muscular dystrophies (500-1500 IU/L).

ii. In female carriers of X-linked muscular dystrophy (heterozygous), CK is moderately raised.

iii. CK level is highly elevated in crush injury, fracture and acute cerebrovascular accidents.

iv. Estimation of total CK is employed in muscular dystrophies and MB iso-enzyme is estimated in myocardial infarction.

CARDIAC TROPONINS (CTI/CTT)

They are not enzymes. However, Troponins are now accepted as reliable markers for myocardial infarction, and hence discussed here. Some more details on troponin are given in Chapter 52. Measurement of cardiac troponins have become

one of the main tests in early detection of an ischemic episode and in monitoring the patient.

i. The troponin complex consists of 3 components: troponin C (calcium binding subunit), troponin I (actomyosin ATPase inhibitory subunit), and troponin T (tropomyosin binding subunit).

ii. Troponin I (TnI) is encoded by 3 different genes, giving rise to 3 isoforms; the "slow" and "fast" moving forms are skeletal variety. Cardiac isoform is specific for cardiac muscle; the amino acid sequence is different in skeletal muscle isoform. Cardiac isoform of CTnT and CTnI are mainly (95%) located in myofibrils and the remaining 5% is cytoplasmic. Circulating isoforms may be ternary complexes (TIC) or binary complexes (IC) or free subunits of I and T. They are generally identified and quantitated by immunological (ELISA or immuno turbidimetric) reactions. Troponins are seen in skeletal and cardiac muscles, but not in smooth muscles.

iii. Troponin I is released into the blood within 4 hours after the onset of symptoms of myocardial ischemia; peaks at 14-24 hours and remains elevated for 3-5 days post-infarction. Therefore, CTI is very useful as a marker at any time interval after the heart attack. It is not increased in muscle injury; whereas CK2 may be elevated in some muscle injury. The initial increase is due to liberation of the cytoplasmic fraction and sustained elevation is due to the release from myofibrils.

iv. Serum level of Troponin T (TnT) increases within 6 hrs of myocardial infarction, peaks at 72 hours and then remains elevated up to 7-14 days.

v. Cardiac troponin elevations at lower concentrations than the 99th percentile value used for MI diagnosis may identify patients who have not had an MI but still have a risk of having an adverse cardiac event.

**LACTATE DEHYDROGENASE (LDH) (LD)**

1. **Reference Values**

LDH will convert pyruvate to lactate (Chapter 9). **Normal value** of LDH in serum is 100-200 U/L. Values in the upper range are generally seen in children. Strenuous exercise will slightly increase the value. LDH level is 100 times more inside the RBC than in plasma, and therefore minor amount of hemolysis will result in a false positive test.

2. **LDH and Heart Attack**

In myocardial infarction, total LDH activity is increased, while H4 iso-enzyme is increased 5-10 times more. The time course of LDH level after a heart attack is given in Figure 23.1. The magnitude of the peak value as well as the area under the graph will be roughly proportional to the size of the myocardial infarct.

3. **Differential Diagnosis**

Increase in total LDH level is seen in hemolytic anemias, hepatocellular damage, muscular dystrophy, carcinomas, leukemias, and any condition which causes necrosis of body cells. Since total LDH is increased in many conditions, the study of iso-enzymes of LDH is of more significance.

4. **Iso-enzymes of LDH**

i. LDH enzyme is a tetramer with 4 subunits. But the subunit may be either H (heart) or M (muscle) polypeptide chains. Although both of them have the same molecular weight (32 kD), there are minor amino acid variations.

Fig. 23.3. Electrophoresis of LDH
concentrations of BNP predict poor long-term survival. In breathlessness, BNP test helps in the differentiation of the cause as heart failure or obstructive lung disease. Patients with COPD (chronic obstructive pulmonary disease) and worsening of their cor pulmonale with signs of RV volume overload (including edema and ascites) manifested increased BNP levels, and, indeed, these patients had increased mortality. The best marker of ventricular dysfunction is pro-BNP.

**Brain Natriuretic Peptide (BNP)**

The natriuretic peptide family consists of three peptides: atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP), and C-type natriuretic peptide (CNP). The clinical significance of CNP is not clear. ANP is produced primarily in the cardiac atria.

BNP is present in human brain, but more in the cardiac ventricles. Human pro–BNP contains 108 amino acids. It is cleaved by enzymes within cardiac myocytes into the active C-terminal BNP (32 amino acids) and an inactive peptide (proBNP 1–76). Both are seen in circulation. The active BNP is secreted by the ventricles of the heart in response to excessive stretching of heart muscle cells (cardiomyocytes). These natriuretic peptides defend against excess salt and water retention.

Patients with congestive heart failure have high plasma concentrations of ANP and BNP. The concentrations are correlated with the extent of ventricular dysfunction. High concentrations of BNP predict poor long-term survival.

**Enzyme Profiles in Liver Diseases**

Please see Box 23.3.

**Box 23.3. Enzyme Profile in Liver Diseases**

Enzymes commonly studied for diagnosis of liver diseases are:
1. Alanine amino transferase (ALT)
2. Alkaline phosphatase (ALP)
3. Nucleotide phosphatase (NTP)
4. Gamma glutamyl transferase (GGT)

**ALANINE AMINO TRANSFERASE (ALT)**

i. In old literature, it was called as serum glutamate pyruvate transaminase (SGPT). AST needs pyridoxal phosphate (vitamin B6) as co-enzyme.

ii. Normal serum level of AST ranges from 8 to 20 U/L. It is a marker of liver injury and shows moderate to drastic increase in parenchymal liver diseases like hepatitis and malignancies of liver.

iii. AST was used as a marker of myocardial ischemia in olden days. The level is significantly elevated in myocardial infarction. The time course of AST increase in blood is given in Figure 23.2.

iv. But troponins have replaced AST as a diagnostic marker in ischemic heart disease.

**ALKALINE PHOSPHATASE (ALP)**

i. ALP is a nonspecific enzyme which hydrolyses aliphatic, aromatic or heterocyclic compounds. The pH optimum for the enzyme reaction is between 9 and 10. It is activated by magnesium and manganese. Zinc is a constituent ion of ALP.

ii. It is produced by osteoblasts of bone, and is associated with the calcification process (Chapter 35). It is localised in cell membranes (ecto-enzyme), and is associated with transport mechanisms in liver, kidney and intestinal mucosa.

iii. Normal serum value of ALP is 40-125 U/L.

In children the upper level of normal value may
be more, because of the increased osteoblastic activity in children.

iv. **Moderate (2-3 times) increase** in ALP level is seen in hepatic diseases such as infective hepatitis, alcoholic hepatitis or hepatocellular carcinoma (Chapter 26).

v. **Very high levels of ALP** (10-12 times of upper limit) may be noticed in extrahepatic obstruction (obstructive jaundice) caused by gallstones or by pressure on bile duct by carcinoma of head of pancreas. Intrahepatic cholestasis may be due to virus (infective hepatitis) or by drugs (chlorpromazine). ALP is produced by epithelial cells of biliary canaliculi and obstruction of bile with consequent irritation of epithelial cells leads to secretion of ALP into serum.

vi. **Drastically high levels of ALP** (10-25 times of upper limit) are seen in bone diseases where osteoblastic activity is enhanced such as Paget’s disease (osteitis deformans), rickets, osteomalacia, osteoblastoma, metastatic carcinoma of bone and hyperparathyroidism.

**Iso-enzymes of Alkaline Phosphatase**

1. **Alpha-1 ALP** moves in alpha-1 position, it is synthesized by epithelial cells of biliary canaliculi. It is about 10% of total activity and is increased in obstructive jaundice.

2. **Alpha-2 heat labile ALP** is stable at 56°C; but loses its activity when kept at 65°C for 30 minutes. It is produced by hepatic cells. This liver iso-enzyme forms about 25% of total ALP.

3. **Alpha-2 heat stable** ALP will not be destroyed at 65°C, but is **inhibited by phenylalanine**. It is of placental origin, which is found in blood in normal pregnancy. An iso-enzyme closely resembling the placental form is characteristically seen in circulation in about 15% cases of carcinoma of lung, liver and gut and named as **Regan iso-enzyme** (after the first patient in whom it was detected) or carcino-placental iso-enzyme. Normal level is only 1% of the total ALP.

4. **Pre-beta ALP** is of bone origin and elevated levels are seen in bone diseases. This is heat labile (destroyed at 56°C, 10 min). This constitutes about 50% of normal ALP activity. Heat labile bone iso-enzyme of alkaline phosphatase (BAP) is a marker of bone disease.

5. **Gamma-ALP** is inhibited by phenylalanine and originates from intestinal cells. It is increased in ulcerative colitis. About 10% of plasma ALP are of intestinal origin.

6. **The leukocyte alkaline phosphatase** (LAP) is significantly decreased in chronic myeloid leukemia. It is increased in lymphomas.

**Nucleotide Phosphatase (NTP)**

1. It is also known as 5’ nucleotidase. This enzyme hydrolyses 5’ nucleotides to corresponding nucleosides at an optimum pH of 7.5. **Nickel ions** inhibit NTP but not ALP.

2. It is a marker enzyme for plasma membranes and is seen as an ecto-enzyme (enzyme present on the cell membrane).

3. Normal NTP level in serum is 2-10 IU/L. It is moderately increased in hepatitis and highly elevated in biliary obstruction. Unlike ALP, the level is unrelated with osteoblastic activity and therefore is unaffected by bone diseases.

**Gamma Glutamyl Transferase (GGT)**

1. The old name was gamma glutamyl transpeptidase. It can transfer gamma glutamyl residues to substrate. In the body it is used in the synthesis of glutathione (Chapter 15). GGT has 11 iso-enzymes. It is seen in liver, kidney, pancreas, intestinal cells and prostate gland.

2. **Normal serum** value of GGT is 10-30 U/L. It is moderately increased in infective hepatitis and prostate cancers.

3. GGT is clinically important because of its sensitivity to detect alcohol abuse. GGT is increased in alcoholics even when other liver function tests are within normal limits. GGT level is rapidly decreased within a few days when the person stops to take alcohol. Increase in GGT level is generally proportional to the amount of alcohol intake.

**PROSTATE SPECIFIC ANTIGEN (PSA)**

1. It is produced from the secretory epithelium of prostate gland. It is normally secreted into seminal fluid, where it is necessary for the liquefaction of seminal coagulum.

2. It is a serine protease, and is a 32 kD glyco-protein. In blood it is bound to alpha-2-macro-globulin and alpha-1-antitrypsin; a very small fraction is in the free form also.

3. Normal value is 1-5 microgram/L. It is very specific for prostate activity. Values above 10 microgram/L is indicative of prostate cancer.

**ACID PHOSPHATASE (ACP)**

1. It hydrolyses phosphoric acid ester at pH between 4 and 6. **Normal serum** value for ACP is 2.5-12 U/L.

2. ACP is secreted by prostate cells, RBC, platelets and WBC.

3. The prostate iso-enzyme is inactivated by tartaric acid. Normal level of tartrate labile fraction of ACP is 1 U/L.

4. ACP total value is increased in prostate cancer and highly elevated in bone metastasis of
prostate cancer. In these conditions, the tartrate labile iso-enzyme is elevated. This assay is very helpful in follow-up of treatment of prostate cancers. So, ACP is an important tumor marker (Chapter 51).

5. Since blood cells contain excess quantity of ACP, care must be taken to prevent hemolysis while taking blood from the patient. Prostate massage may also increase the value. So blood may be collected for ACP estimation before rectal examination of patient.

Cholinesterase (ChE)

i. Acetyl cholinesterase or true ChE or Type 1 ChE can act mainly on acetyl choline. It is present in nerve endings and in RBCs.

ii. Organophosphorus insecticides (Parathione) irreversibly inhibit ChE in RBCs. Measurement of ChE level in RBCs is useful to determine the amount of exposure in persons working with these insecticides.

iii. Pseudo cholinesterase or type II ChE is nonspecific and can hydrolyse acyl esters. It is produced mainly by liver cells. Succinyl choline is a widely used muscle relaxant. It is a structural analogue of ACh, and so competitively fixes on post-synaptic receptors of ACh. Succinyl choline is hydrolysed by the liver ChE within 2–4 minutes. But in certain persons the ChE activity may be absent; this is a genetically transmitted condition. In such individuals when succinyl choline is given during surgery, it may take hours to get the drug metabolized. Very prolonged ‘scoline apnea’ may result in ‘nightmare of anesthetist’.

Glucose-6-phosphate Dehydrogenase

1. It is a dimer with identical subunits. It is an important enzyme in the hexose monophosphate shunt pathway of glucose (Chapter 10). It is mainly used for production of NADPH.

2. Hydrogen peroxide is continuously formed inside the RBC. Peroxide will destroy RBC cell membrane. Glutathione and NADPH will prevent this process. Therefore, NADPH is very essential for preserving the RBC integrity.

3. Drug Induced Hemolytic Anemia: Normal value of GPD in RBC is 6-12 U/g of Hb. This is reduced in drug induced hemolytic anemias. In the GPD deficient individuals, RBC life-span may be reduced, but there will be no disease manifestations. But when certain drugs (aspirin, mepacrine, primaquine, sulpha) are taken by such individuals, there will be sudden damage to RBCs. Primaquin stimulates peroxide formation. In G6PD deficient cells the level of NADPH is low, leading to unchecked build up of peroxides resulting in premature cell lysis. This drug-induced hemolytic anemia is characteristic of GPD deficiency. Fava beans (star beans, corner beans) may also induce hemolytic anemia which is called favism.
4. Carrier state has biological advantage: The gene for GPD is located in X-chromosome. Therefore hemizygous males and homozygous females will manifest the disease, while heterozygous females are carriers. In heterozygous condition, where one gene is abnormal and the allelic form is normal, the GPD level in RBC is half the normal value. GPD deficiency seems to protect the person from falciparum malaria. The malarial parasites require NADPH for optimal growth. Thus, GPD deficiency has a selective advantage in malaria-infested regions (Chapters 10 and 22).

5. Met-hemoglobinemia: NADPH is also necessary for reduction of met-hemoglobin (oxidised form) to hemoglobin (Chapter 22). Hence in GPD deficient individuals, met-hemoglobinemia may also be manifested.

6. Nearly 400 variants (isoforms) of GPD are described. Some of the variants have decreased enzyme activity.

AMYLASE
1. The enzyme splits starch to maltose. It is activated by calcium and chloride ions. It is produced by pancreas and salivary glands.
2. Normal serum value is 50-120 IU/L. The value is increased about 1000 times in acute pancreatitis which is a life-threatening condition. The peak values are seen between 5-12 hours after the onset of disease and returns to normal levels within 2-4 days after the acute phase has subsided.
3. Moderate increase in serum levels are seen in chronic pancreatitis, mumps (parotitis) and obstruction of pancreatic duct.

</tbody>
</table>

4. Normal value of amylase in urine is less than 375 U/L. It is increased in acute pancreatitis. It is increased on the 1st day and remains to be elevated for 7-10 days.

LIPASE
It will hydrolyse triglyceride to beta-monoglyceride and fatty acid. The enzyme is present in pancreatic secretion. The level in blood is highly elevated in acute pancreatitis and this persists for 7-14 days. Thus, lipase remains elevated longer than amylase. Moreover, lipase is not increased in mumps. Therefore, lipase estimation has advantage over amylase. It is moderately increased in carcinoma of pancreas, biliary diseases and perforating peptic ulcers.

ENOLASE
It is a glycolytic enzyme. Neuron-specific enolase (NSE) is an iso-enzyme seen in neural tissues and Apudomas. NSE is a tumor marker (Table 51.8) for cancers associated with neuroendocrine origin, small cell lung cancer, neuroblastoma, pheochromocytoma, medullary carcinoma of thyroid, etc. It is measured by RIA or ELISA.

Enzyme patterns in some important diseases are given in Box 23.4. Important enzymes in body fluids are shown in Table 23.5.

Aldolase (ALD)
It is a tetrameric enzyme with A and B subunits; so there are 5 iso-enzymes. It is a glycolytic enzyme. Normal range of serum is 1.5-7 U/L. It is drastically elevated in muscle damages such as progressive muscular dystrophy, poliomyelitis, myasthenia gravis and multiple sclerosis. It is a very sensitive early index in muscle wasting diseases.

Ceruloplasmin
It is otherwise called Ferroxidase, and is described in detail in Chapter 28. Normal serum level is 25-50 mg/dl. It is estimated...
by the ability of ceruloplasmin to oxidise paraphenylene diamine to a purple compound, which is colorimetrically read at 530 nm. Modern techniques based on radial immunodiffusion or immunoturbidimetric methods are also available. Since it is an acute phase protein, it is increased in all inflammatory conditions, collagen diseases, malignancies and pregnancy. A value less than 20 mg/dl is pathognomonic of Wilson’s hepatolenticular degeneration, in which copper toxicity is manifested (see under copper, Chapter 35).

**Enzymes as Therapeutic Agents**

**Streptokinase** (from Streptococcus) or **Urokinase** (from urine) can lyse intravascular clots and are therefore used in myocardial infarction. **Pepsin** and **trypsin** are given to patients with defective digestion. **Asparaginase** is used as an anticancer drug. A list of therapeutically useful enzymes is given in Table 23.4.

**Enzymes Used for Diagnosis**

A list of enzymes used in clinical laboratory is given in Table 23.6. Methods for blood analyte estimations are made specific by using enzymes. For example, **glucose oxidase** is used to estimate glucose. **Urease** will act only on urea, and therefore, it is conveniently used to quantitate urea in biological fluids. The presence of antibody in circulation is identified by fixing them on antigen and identified by a second antibody tagged with **peroxidase**. These enzymes are effective to produce a color reaction. This **ELISA test** is described in detail in Chapter 54. **Restriction endonucleases** are used to cut DNA at specific sites; and applied in recombinant DNA technology, Southern blotting, and other advanced techniques (Chapter 55).

**Immobilized Enzymes**

Enzymes have been fixed or rendered insoluble by attaching them to insoluble matrix such as plastic beads or cellulose strips. These strips are used for detection of abnormal substances in blood or urine. For example, a strip of paper coated with immobilized **glucose oxidase** (GOD) and peroxidase (POD) enzymes is used for detection of glucose in urine. The following reactions take place:

\[
\text{Glucose} + \text{O}_2 + \text{H}_2\text{O} \rightarrow (\text{GOD}) \rightarrow \text{Gluconic acid} + \text{H}_2\text{O}_2
\]

\[
\text{H}_2\text{O}_2 \rightarrow (\text{POD}) \rightarrow \text{H}_2\text{O} + \text{Nascent O}
\]

O-toluidine(colorless) + O \rightarrow oxidised toluidine(blue)

Similarly immobilized urease, hexokinase, amylase etc. are also used for diagnostic purpose.

**Related Topics**

Tumor markers are described in Chapter 51.

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Factors maintaining blood glucose
2. Normal plasma glucose level
3. Effects of hormones on glucose level
4. Oral glucose tolerance test (OGTT)
5. Diagnostic criteria for diabetes mellitus
6. Impaired glucose tolerance
7. Reducing substances in urine
8. Benedict's test
9. Insulin, synthesis and secretion
10. Physiological action of insulin
11. Glucagon
12. Diabetes mellitus types
13. Metabolic derangements in diabetes
14. Clinical aspects of diabetes mellitus
15. Laboratory investigations in diabetes
16. Glycated hemoglobin

REGULATION OF BLOOD GLUCOSE
The maintenance of glucose level in blood within narrow limits is a very finely and efficiently regulated system. This is important, because it is essential to have continuous supply of glucose to the brain. Even though it can utilize ketone bodies to some extent, brain has an obligatory requirement for glucose. RBC and renal medulla are also dependent on glucose for meeting their fuel needs. Factors maintaining the blood glucose are shown in Box 24.1 and Figures 24.1 and 24.3.

Post-prandial Regulation
Following a meal, glucose is absorbed from the intestine and enters the blood. The rise in the blood glucose level stimulates the secretion of insulin by beta cells of islets of Langerhans of pancreas. The uptake of glucose by most extrahepatic tissues, except brain is dependent on insulin. Moreover, insulin helps in the storage of glucose as glycogen or its conversion to fat (Fig. 24.2A).

Box 24.1: Factors Maintaining Blood Sugar
1. The plasma glucose level at an instant depends on the balance between glucose entering and leaving the extracellular fluid.
2. Hormones will make this balance possible (Fig. 24.1).
3. The major factors which cause entry of glucose into blood are:
   a. Absorption from intestines
   b. Glycogenolysis (breakdown of glycogen)
   c. Gluconeogenesis
   d. Hyperglycemic hormones (glucagon, steroids)
4. Factors leading to depletion of glucose in blood are:
   a. Utilization by tissues for energy
   b. Glycogen synthesis
   c. Conversion of glucose into fat (lipogenesis)
   d. Hypoglycemic hormone (insulin)

Fig. 24.1. Homeostasis of blood glucose
Regulation in Fasting State

i. Normally, 2 to 2½ hours after a meal, the blood glucose level falls to near fasting levels. It may go down further; but this is prevented by processes that contribute glucose to the blood.

ii. For another 3 hours, hepatic glycogenolysis will take care of the blood glucose level.

iii. Thereafter, gluconeogenesis will take charge of the situation (Figs 24.2A and B).

iv. Liver is the major organ that supplies the glucose for maintaining blood glucose level (Fig. 24.1).

v. Hormones like glucagon, epinephrine, glucocorticoids, growth hormone, ACTH and thyroxine will keep the blood glucose level...
from falling. They are referred to as anti-insulin hormones or hyperglycemic hormones. An overview of the regulatory mechanism is shown in Figure 24.3. Effects of hormones are shown in Box 24.2.

**Determination of Glucose in Body Fluids**

Estimation of glucose is the most common analysis done in clinical laboratories. The blood is collected using an anticoagulant (potassium oxalate) and an inhibitor of glycolysis (sodium fluoride). Plasma is separated for glucose estimation.

Fluoride inhibits the enzyme, enolase, and so glycolysis on the whole is inhibited. If fluoride is not added, cells will utilize glucose and false low value may be obtained. Capillary blood from fingertips may also be used for glucose estimation by strip method. Modern techniques use serum samples also.

**Enzymatic Method**

This is highly specific, giving ‘true glucose' values (fasting 70-110 mg/dl). Present day autoanalyzers can use only the enzymatic methods.

The glucose oxidase (GOD) method is the one most widely used. Glucose oxidase is very specific; it converts glucose to gluconic acid and hydrogen peroxide. Peroxidase converts the H₂O₂ into H₂O and nascent oxygen. The oxygen oxidises a colorless chromogenic substrate (e.g. ortho di-anisidine) to a colored one; the color intensity is directly proportional to concentration of glucose.

As a modification, the above GOD reaction mixture is immobilized on a plastic film (dry analysis). One drop of blood is placed over the reagent. The color is developed within one minute. The intensity of dye is measured by reflectance photometry. The instrument is named as glucometer. It is useful for self monitoring of blood glucose (SMBG) by patients at home. But the instrument is less accurate.

**Commonly Employed Terms Regarding Glucose**

1. Plasma glucose analyzed at any time of the day, without any prior preparations, is called **random plasma glucose**.
2. Sugar estimated in the early morning, before taking any breakfast is called **fasting plasma glucose**. Fasting state means, glucose is estimated after an overnight fast (12 hours after the food) (post-absorptive state).
3. The test done about 2 hr after a good meal is called **post-prandial plasma glucose** (Latin = after food).
4. When plasma glucose level is within normal limits, it is referred to as **normoglycemia**. When values are above the normal range, it is known as **hyperglycemia**. When values are below the normal range, it is called **hypoglycemia**. (Greek, hyper = above; hypo = below).
5. When the plasma glucose is below 50 mg/dl, it is a very serious condition. Hyperglycemia is harmful in the long run; while hypoglycemia even for a short while is dangerous, and may even be fatal.
6. The plasma values are slightly higher than whole blood glucose values because RBCs contain less water (73%) than plasma (93%).
7. The ability of a person to metabolise a given load of glucose is referred to as **glucose tolerance**.

**Conducting the Glucose Tolerance Test**

1. At about 8 am, a sample of blood is collected in the fasting state. Urine sample is also obtained. This is denoted as the "0" hour sample.
2. **Glucose Load Dose**: The dose is 75 g anhydrous glucose (82.5 g of glucose monohydrate) in 250-300 ml of water. This dose is fixed for an adult, irrespective of body weight. (When the test is done in children, the glucose dose is adjusted as 1.75 g /kg body weight). In order to prevent vomiting, patient is asked to drink it slowly (within about 5 minutes). Flavouring of the solution will also reduce the tendency to vomit.
3. **Sample Collection**: As per current WHO recommendations, 2 samples are collected, one
at fasting ("0" hr sample) and 2 hr post-glucose load. Urine samples may also be collected along with these blood samples. This is sufficient to get a correct assessment of the patient.

**Normal Values and Interpretations**

As per WHO recommendation, in a normal person, fasting plasma glucose is 70-110 mg/dl. The present day tendency is to view values above 100 mg/ml as suspicious. According to the recommendations of the American Diabetic Association, the revised upper limit is 100 mg/dl, above which a person has to be further tested periodically. Currently the International Diabetes Federation says that a value more than 100 mg/dl is one of the criteria for the metabolic syndrome.

Following the glucose load, the level rises and reaches a peak within 1 hour and then comes down to normal fasting levels by 2 to 2½ hours. This is due to the secretion of insulin in response to the elevation in blood glucose. None of the urine sample shows any evidence of glucose. Diagnostic criteria for diabetes mellitus are given in Table 24.1 and Box 24.3. Oral glucose tolerance test and physiological tolerance test are different (Box 24.4).

**Classical Oral Glucose Tolerance Test (OGTT)**

The above mentioned method is sufficient to assess the condition of most of the patients, and modern day tendency is to take only 2 blood samples, as described above. However, in selected cases, the conventional OGTT may be employed, where 6 blood samples are taken, and the procedure is given below. Glucose tolerance test is artificial, because in day-to-day life, such a large quantity of glucose does not enter into blood. However, the GTT is a well-standardized test, and is highly useful to diagnose diabetes mellitus in doubtful cases.

**Indications for OGTT**
1. Patient has symptoms suggestive of diabetes mellitus; but fasting blood sugar value is inconclusive (between 100 and 126 mg/dl).
2. During pregnancy, excessive weight gaining is noticed, with a past history of big baby (more than 4 kg) or a past history of miscarriage.
3. To rule out benign renal glucosuria.

**Contraindications for OGTT**
1. There is no indication for doing OGTT in a person with confirmed diabetes mellitus.
2. GTT has no role in follow-up of diabetes. It is indicated only for the initial diagnosis.
3. The test should not be done in acutely ill patients.

**Preparation of the Patient**
1. The patient is instructed to have good carbohydrate diet for 3 days prior to the test. Further, diet containing about 30-50 g of carbohydrate should be taken on the evening prior to the test. This is important. Otherwise carbohydrates may not be tolerated even in a normal person.
2. Patient should avoid drugs likely to influence the blood glucose levels, for at least 2 days prior to the test. Patient should abstain from smoking during the test. Strenuous exercise on the previous day is to be avoided.
3. Patient should not take food after 8 PM the previous night. Should not take any breakfast. This is to ensure 12 hours fasting.
4. The patients are advised to remain in the hospital during the waiting period of two hours without any active exercise. The practice of leaving the hospital and rushing back at the end of 2 hours should be discouraged.

**Difference between modern and classical GTT**

Glucose load given is the same in both instances. In the classical procedure, the blood and urine samples are collected...
**Box 24.3. Diagnostic Criteria for Diabetes Mellitus**

1. If the fasting plasma glucose is more than 126 mg/dl, on more than one occasion.
2. Or, if 2 hr post-glucose load value of OGTT is more than 200 mg/dl (even at one occasion).
3. Or, if both fasting and 2 hr values are above these levels, on the same occasion.
4. If the random plasma glucose level is more than 200 mg/dl, on more than one occasion. Diagnosis should not be based on a single random test alone; it should be repeated.

at ½ an hour intervals for the next 2½ hours. (Total six samples, including 0 hr sample). Glucose is estimated in all the blood samples. Urine samples are tested for glucose qualitatively. In modern times, only 2 blood samples are collected.

Figure 24.4 represents the graph, when plasma glucose values are plotted on the vertical axis against the time of collection on the horizontal axis.

**Causes for Abnormal GTT Curve**

1. Impaired Glucose Tolerance (IGT)
   It is otherwise called as **Impaired Glucose Regulation** (IGR). Here plasma glucose values are above the normal level, but below the diabetic levels (see Table 24.1).
   In IGT, the fasting plasma glucose level is between 110 and 126 mg/dl and 2-hour post-glucose value is between 140 and 200 mg/dl (Fig. 24.4).
   Such persons need careful follow-up because IGT progresses to frank diabetes at the rate of 2% patients per year.

2. Impaired Fasting Glycemia (IFG)
   In this condition, fasting plasma glucose is above normal (between 110 and 126 mg/dl); but the 2 hour post-glucose value is within normal limits (less than 140 mg/dl). These persons need no immediate treatment; but are to be kept under constant check up.

3. Gestational Diabetes Mellitus (GDM)
   This term is used when carbohydrate intolerance is noticed, for the first time, during a pregnancy. A known diabetic patient, who becomes pregnant, is not included in this category.
   In all antenatal women, a glucose challenge test is done between 22 and 24 weeks of pregnancy by giving an oral glucose load of 50 g of glucose regardless of the time. If the 2-hour post-glucose value is more than 140 mg/dl, the test is positive. An OGTT with 75 g glucose load should be done to confirm or exclude GDM. Some obstetricians prefer to do an OGTT without a screening test with 75 gm of glucose. In these cases, three blood samples are drawn, fasting, 1 hour and 2-hour post-glucose load.
   Women with GDM are at increased risk for subsequent development of frank diabetes. GDM is associated with an increased incidence of neonatal mortality. Maternal hyperglycemia causes the fetus to secrete more insulin, causing stimulation of fetal growth and increased birth weight. After the child birth, the women should be re-assessed.

4. Alimentary Glucosuria
   Here the fasting and 2 hr values are normal; but an exaggerated rise in blood glucose following the ingestion of glucose is seen. This is due to an increased rate of absorption of glucose from the intestine. This is seen in patients after a gastrectomy or in hyperthyroidism.

5. Renal Glucosuria
   Normal renal threshold for glucose is 175-180 mg/dl. If blood glucose rises above this, glucose starts to appear in urine.
   Generally, the increased blood glucose level is reflected in urine. But when renal threshold is lowered, glucose is excreted in urine. Renal tubular reabsorption is lowered, as the SGLT2 is abnormal.

Oral glucose tolerance test (OGTT) is always non-physiological, where glucose is administered in a large dose. But it is a very standard test, and is useful for diagnosis. In this test, the plasma glucose reaches a peak value at 1 hour and comes back to fasting value by about 2 hours. These are referred to as post-glucose load values.

This OGTT is different, and should not be confused, with the physiological tolerance test often employed in clinical practice. Here fasting blood sample is taken; then patient is asked to take a heavy breakfast (instead of glucose load). This will certainly mimic what is happening in daily life. The blood sample at 2 hr after the meal is also taken; when the result is referred to as post-prandial (Latin, after food) value. In normal persons, the 2 hr post-prandial value will be less than 140 mg/dl.
In these cases, the blood glucose levels are within normal limits. This is called renal glycosuria. Renal threshold is lowered physiologically in pregnancy; it is a harmless condition; it will not progress. About 10% women, pregnant women show renal glucosuria in the last trimester of pregnancy. Renal glucosuria is associated with renal diseases with renal tubular transport defects; e.g. Fanconi's syndrome. In these cases glucosuria is seen along with amino aciduria and phosphaturia.

In some cases, renal threshold may be increased when glucose will not appear in urine, even though blood glucose is elevated. Here, GFR is decreased with minimal or no impairment of tubular reabsorption. This is seen in old age (arteriosclerosis) and in Kimmelsteil-Wilson syndrome (diabetic nephrosclerosis).

Factors Affecting GTT
1. Insulin level; GTT is used to detect insulin deficiency.
2. Carbohydrate starvation. Therefore, patient is advised to take carbohydrate-rich diet for 3 days before test.
3. Exercise. Patient is advised to take rest during and prior to the test.
4. In liver diseases, curve is elevated and prolonged.
5. In acute infections, cortisol is secreted, and so curve is elevated and prolonged.
6. In hyperthyroidism there will be steep rise in curve. A flat curve is seen in hypothyroidism.

Corticosteroid Stressed GTT
Cortisone (100 mg) in 2 divided doses are given orally, 8 hours and 2 hours prior to the test. Then glucose is given orally. Normal blood sugar values in this test will be at 1 hour < 180 mg/dl and at 2 hours < 160 mg/dl. The values will be high in persons who are in pre-diabetic state or in persons prone to get diabetes in future. The cortisone primed test has very limited use; and is seldom done nowadays.

Intravenous GTT
This test is done in patients with suspected malabsorption, where results of oral GTT may not be conclusive. Then patient is advised for fast for 12 hr. In the morning 25 g of glucose in 100 ml sterile distilled water is given as intravenous injection within 5 min. Completion of infusion is taken as 0 time. Blood samples are taken at 10 min intervals for the next hour. Peak value is reached within a few minutes (200-250 mg/dl). The value reaches 100 mg/dl by 45-60 min in normal persons.

REDDUCING SUBSTANCES IN URINE
Normally glucose is not excreted in urine. But if blood glucose is more than 180 mg/dl, urine contains glucose. The blood level of glucose above which glucose is excreted is called renal threshold.

The excretion of reducing substances in urine is detected by a positive Benedict's test (see Chapter 6). About 0.5 ml of urine is boiled with 5 ml Benedict's reagent for 2 minutes (or kept for 2 minutes in water bath which is already boiling). The formation of a precipitate is observed on cooling. The test is semi-quantitative and the color of the precipitate roughly parallels the concentration of reducing sugar. Blue color indicates the absence of sugar in urine. The green precipitate means 0.5%; yellow (1%); orange (1.5%) and red indicates 2% or more of sugar (1% means 1 g per 100 ml). Nowadays, strips are available, which when dipped in urine will give the color, if it contains sugar.

Any reducing sugar will give a positive Benedict’s test. So differentiation of various sugars which may be present in urine has practical importance. Such conditions together are sometimes called as "mellituria". The substances in urine answering Benedict’s test are enumerated in Table 24.2. Differential diagnosis of a positive Benedict’s test is shown in Box 24.5.

</tr>
</tbody>
</table>
When reducing sugars are excreted in urine, the condition is referred to as **glycosuria**. To denote the excretion of specific sugars the suffix 'uria' is added to the name of the sugar, e.g. **glucosuria**, fructosuria, lactosuria. Glucosuria means glucose in urine; glycosuria means any sugar in urine. Since glucose is the most common reducing sugar excreted in urine, the term glycosuria is often (though incorrectly) used to denote the excretion of glucose.

**Hyperglycemic glucosuria**

i. When blood glucose level exceeds the renal threshold (175-80 mg/dl), glucose is excreted in urine. **Diabetes mellitus** is the most common cause.

ii. **Transient glucosuria.** It may occur in some people due to emotional stress. Excessive secretion of anti-insulin hormones like cortisol (anxiety) and thyroid hormone may cause glucosuria. Once the stress is removed, the glucosuria disappears.

iii. **Renal glucosuria**

iv. **Alimentary glucosuria;** both are described under glucose tolerance test.

**Lactosuria**

It is the second most common reducing sugar found in urine. It is observed in the urine of normal women during 3rd trimester of pregnancy and lactation. The condition is harmless. In pregnancy, it is important to distinguish lactosuria from glucosuria when gestational diabetes mellitus is suspected. Methyl amine test will be positive for lactose. To 5 ml of urine 1 ml of methylamine in sodium hydroxide is added. When kept at 56°C for 30 min, red color develops indicating the presence of lactose.

**Fructosuria**

In hereditary fructose intolerance, due to the absence of the enzyme Aldolase B, fructose is not metabolized, and so excreted in urine (Chapter 10). Seliwanoff's test will distinguish glucose and fructose. The reagent is resorcinol in HCl. 3 ml of the reagent and 0.5 ml of urine is heated for 30 seconds (up to boiling point). The appearance of red color indicates the presence of fructose.

**Galactosuria**

Urine contains galactose in patients with absence of galactose-1-phosphate uridyl transferase (Chapter 10). Mucic acid test will be positive. Boiling the urine with nitric acid will lead to formation of crystals of mucic acid when either lactose or galactose is present.

**Pentosuria**

i. Essential pentosuria is characterised by the excretion of **L-xylulose** in urine due to deficiency of any of the two enzymes xylitol dehydrogenase or xylulose reductase (see Chapter 10). It is a harmless condition.

ii. Rarely alimentary pentosuria may occur due to ingestion of cherries, berries and plums.

iii. Bial's test will be positive. The reagent contains orcinol in HCl. 0.5 ml of urine and 5 ml of Bial's reagent are heated to boil. A green color indicates the presence of pentoses.

**Non-carbohydrate Reducing Compounds**

i. **Glucuronides:** Many drugs, e.g. isonictonic acid, para-amino salicylate, penicillin, cephaloxin, nalidixic acid are excreted as conjugates of glucuronic acid. In alkaline conditions, the glucuronic acid is released, which is a powerful reducing agent. So, Benedict's test will be positive.

ii. **Salicylates:** Salicylic acid is conjugated with glycine and excreted in urine. This can give a positive test. But test becomes negative when the drug is withdrawn.

iii. **Ascorbic acid:** Ascorbic acid or vitamin C is a very common ingredient of many tonics. Persons taking such tonics will excrete ascorbic acid in urine. It is a powerful reducing agent. This may cause confusion, as the Benedict's test is positive in such normal individuals.

iv. **Homogentisic acid:** It is an intermediate in the catabolism of the amino acids phenylalanine and tyrosine. It is excreted in **Alkaptonuria**, an inborn error of metabolism (Chapter 17). This causes a yellow precipitate when treated with Benedict's reagent. This can be distinguished by a positive ferric chloride test.

**INSULIN**

The word "insulin" is derived from Latin, insula, meaning island (islet). In 1869, Langerhans identified the alpha and beta cells...
in islets of pancreas. In 1889, von Mering and Minkowski produced experimental diabetes by pancreatectomy. In 1922, Banting and Best extracted insulin from pancreas. Insulin was the first hormone to be isolated in a pure form. They injected the extract to a diabetic dog, Marjorie, who was kept alive by regular insulin injections. For this work Banting was awarded Nobel prize in 1923. But Best was deleted in the list and instead John Macleod, the Director of the institution was awarded the Nobel prize. As a compensation, Banting declared that half his share of the prize will go to Best. Macleod declared that half of his share of prize will go to JB Collip, Professor of Medicine, Toronto Hospital, who first administered insulin to his patients. In 1927, Abel crystallized the insulin. In 1954, Sanger studied the amino acid sequence of insulin; it was the first protein in which complete amino acid sequencing was done. For this work Sanger got Nobel prize in 1958. Insulin is the first protein produced by recombinant DNA technology (1982).

### Structure of insulin
Insulin is a protein hormone with 2 polypeptide chains. The A chain has 21 amino acids and B chain has 30 amino acids. These two chains are joined together by two interchain disulphide bonds, between A7 to B7 and A20 to B19. There is also an intrachain disulphide link in A chain between 6th and 11th amino acids (see Chapter 4, Fig. 4.4). Species variation is restricted to amino acids 8, 9 and 10 of A chain and C terminal of B chain.

### Biosynthesis of insulin
i. Insulin is a protein synthesized and secreted by the beta-cells of the islets of Langerhans of the pancreas.

ii. The insulin is synthesized as a larger precursor polypeptide chain, the *pre-pro-insulin*. It has 109 amino acids. It is rapidly converted to pro-insulin in the endoplasmic reticulum by removal of leader sequence of 23 amino acid residues.

iii. The *proinsulin* with 86 amino acids is transported to Golgi apparatus where it is cleaved by a protease (Fig. 24.5). Thus *C-peptide* or connecting peptide with 33 amino acids is removed. (The number of amino acids in C peptide may vary according to species). Insulin with 51 amino acids is thus formed (Fig. 24.5).

### Secretion of insulin
The insulin is packed into granules. The molecules take shape of a hexamer with 2 zinc ions and one calcium ion. Approximately 50 units of insulin is secreted per day. Normal insulin level in blood is 5-15 microunits/ml. Proinsulin contributes 5 to 10% of the total insulin measured in plasma. Proinsulin has about one-third biological activity as that of insulin. Insulin and C-peptide are synthesized and secreted in equimolar quantities. Therefore, measurement of C-peptide is an index of rate of secretion of insulin. Mutations causing changes in amino acid sequence at the cleavage points can lead to familial pro-insulinemia.

### Factors increasing insulin secretion
1. **Glucose**
   Glucose is the major stimulant of insulin secretion. As blood glucose level increases, the insulin secretion also correspondingly increases. Glucose induces a biphasic response to insulin secretion. A discharge of insulin from the beta cell storage pool occurs during the initial rapid phase of insulin release within first 2 minutes. The second phase of insulin release lasting for 5-10 minutes is of smaller magnitude and is due to discharge of newly synthesized hormone. The beta cells have **Glut 2 receptors** (Chapter 9), through which glucose is absorbed. Glucose is oxidised, so that more ATP is produced. ATP stimulates an **ATP Binding Cassette** protein (ABC protein) which is referred to as Sulfonyl Urea Receptor (SUR). Simultaneously potassium channels are closed and calcium channels are opened (Fig. 24.6). Increased intracellular calcium causes the insulin secretion.

2. **Gastrointestinal hormones**: Insulin secretion is enhanced by secretin, pancreozymin and gastrin. After taking food, these hormones are increased.

3. **Proteins and amino acids**: Leucine and arginine are stimulants.

4. **Parasympathetic and beta-adrenergic stimulation**.

5. **Glucagon and growth hormone**.

6. **Drug, Tolbutamide**.

7. **Incretin hormones**: Glucose dependent insulinotropic polypeptide (GIP, 41 amino acids) and Glucagon like...
peptide 1 (GLP-1, 31 amino acids) are involved in the release of insulin following nutrient entry into stomach. They are both secreted by specialized cells in the gastrointestinal tract and have receptors located in islet cells. They have a very short half life. For treatment of diabetes, new drugs are being developed either to mimic or to target these hormones.

**Factors decreasing the insulin secretion**

1. **Epinephrine**: During stressful conditions and during exercise, adrenal medulla releases adrenaline. This suppresses insulin release, and at the same time, mobilises glucose from liver for energy purpose.

2. **Alpha adrenergic stimulation**.

**Degradation of insulin**

Insulin is rapidly degraded by the liver. **Plasma half-life is less than 5 minutes**. An insulin specific protease (insulinase) is involved in the degradation of insulin.

**Mechanisms of Action of Insulin**

1. **Insulin Receptors**

   Insulin acts by binding to a plasma membrane receptor on the target cells. In obesity, the number of receptors are decreased and target tissue becomes less sensitive to insulin (diabetes mellitus Type 2). Insulin receptor is a glycoprotein with 4 subunits: 2 alpha and 2 beta subunits. The alpha units (135 kD) are located on the extracellular side, to which insulin binds. The beta subunits (95 kD) traverse the membrane and are exposed on the cytoplasmic side (Fig. 24.7). Beta subunit has tyrosine kinase activity.

2. **Signal Transduction**

   Insulin binds to the alpha subunit. This binding activates the tyrosine kinase activity of the beta subunit, leading to auto-phosphorylation of the beta subunit (Fig. 24.7). This event, in turn, phosphorylates insulin receptor substrates (IRS). The message is later transmitted into a series of serine/threonine kinases, such as IRS → Ras → Raf → MAPK, etc. which causes cellular responses. IRS are further described in Chapter 48.

3. **Gene Transcription (new enzyme synthesis)**

   Insulin acts at the transcriptional level to regulate synthesis of more than 100 proteins.

   **3-A. Insulin induces** the following enzymes:
   
   i. Glucokinase
   ii. Pyruvate kinase
   iii. Phospho fructo kinase
   iv. Acetyl CoA carboxylase

   **3-B. Insulin represses** the following enzymes:
   
   i. Glucose-6-phosphatase
   ii. Phospho enol pyruvate carboxy kinase
   iii. Fructose-1,6-bisphosphatase

4. **Activation of Enzymes**

   Insulin activates the existing molecules of enzymes by covalent modification (phosphorylation or dephosphorylation). There are more than 50 enzymes activated by this mechanism. A short selected list is shown in Table 24.3. Insulin activates protein phosphatase I (PPI) which dephosphorylates enzyme proteins.

5. **DNA Synthesis**

   Through the IRS-1 pathway, (see signal transduction) insulin increases DNA synthesis, cell growth and anabolism. In all the above mentioned pathways, intracellular mediators have been implicated in insulin action. These are Ca++ and cyclic AMP. Insulin activates phospho diesterase and thereby decreases cAMP. So, reactions dependent on cAMP are inhibited, e.g. glycogen phosphorylase (Chapter 9).

6. **Glucose Uptake**

   Insulin increases the recruitment of GluT4 in cells.

Chapter 24: Regulation of Blood Glucose, Insulin and Diabetes Mellitus

Physiological Actions of Insulin

(Metabolic Effects of Insulin)

Insulin plays a central role in regulation of the metabolism of carbohydrates, lipids and proteins (see Table 24.4).

1. Uptake of Glucose by Tissues

Insulin facilitates the membrane transport of glucose. Facilitated diffusion of glucose in muscle is enhanced by insulin. In diabetes mellitus, the transporter, GluT4 is reduced (Chapter 9). However, glucose uptake in liver (by GluT2) is independent of insulin.

2. Utilization of Glucose

i. **Glycolysis is stimulated by insulin.** The activity and amount of key glycolytic enzymes (glucokinase, phosphofructokinase and pyruvate kinase) are increased.

ii. **Glycogen synthase enzyme is activated, and so insulin favors glucose storage as glycogen.** (Chapter 9).

iii. **Insulin favors synthesis of fatty acid from glucose and so glucose utilization is increased.**

3. Hypoglycemic Effect

i. **Insulin lowers the blood glucose level by promoting utilization and storage.**

ii. **Glucoseogenesis is inhibited** by insulin by repressing the key enzymes, pyruvate carboxylase (PC) phosphoenol pyruvate carboxykinase (PEPCK) and glucose-6-phosphatase (Chapter 9).

iii. **Insulin inhibits glycogenolysis** by favoring the inactivation of glycogen phosphorylase and inhibiting glucose-6-phosphatase. The net effect of all these three mechanisms, blood glucose level is lowered.

4. Lipogenesis

i. Lipogenesis is favored by providing more acetyl CoA by pyruvate dehydrogenase reaction.

ii. **Insulin increases the activity of acetyl CoA carboxylase** and provides glycerol for esterification of fatty acids to TAG (Chapter 11).

iii. **Insulin also provides NADPH** by increasing the GPD activity of the HMP shunt pathway.

5. Anti-lipolytic Effect

i. Insulin inhibits lipolysis in adipose tissue due to inhibition of hormone sensitive lipase.

ii. The increased level of FFA in plasma in diabetes is due to the loss of this inhibitory effect on lipolysis.

6. Anti-ketogenic Effect

i. **Insulin depresses HMG CoA synthase** and so ketogenesis is decreased.

Moreover, in presence of insulin, acetyl CoA is completely utilized in the citric acid cycle, because oxaloacetate generated from glucose is available in plenty. Insulin also favors fatty acid synthesis from acetyl CoA.

All these factors reduce the availability of acetyl CoA, so that production of ketone bodies reduced.

7. Other General Effects
   i. Protein synthesis is promoted and degradation is retarded.
   ii. It is an **anabolic** hormone.
   iii. Insulin stimulates replication of cells. In fact, insulin is an essential growth factor for all mammalian cells. These effects are summarized in Table 24.4.

**HYPERGLYCEMIC HORMONES**
1. Glucagon
2. Epinephrine or Adrenaline
3. Glucocorticoids
4. ACTH
5. Growth hormone
6. Thyroxine
   All these are anti-insulin hormones.

**GLUCAGON**
It is a polypeptide hormone with 29 amino acids. It is secreted by the alpha cells of pancreas. **Entero-glucagon** is a peptide hormone secreted by duodenal mucosa, having same immunological and physiological properties of glucagon. Glucagon is synthesized as a longer proglucagon precursor.

Glucagon has a half-life in plasma at about 5 minutes. It is inactivated in the liver. The major regulator of secretion of glucagon is glucose. An increase in blood glucose level inhibits secretion of glucagon.

**Physiological Actions of Glucagon**
1. Glucagon is the most potent **hyperglycemic** hormone. It is **anti-insulin** in nature. Therefore, the net effect is decided by the insulin-glucagon ratio (Fig.24.8).
2. Glucagon is mainly **glycogenolytic**. The active form of glycogen phosphorylase is formed under

</table>
the influence of glucagon. Liver is the primary target for the glycogenolytic effect of glucagon.

3. It depresses glycogen synthesis.

4. **Gluconeogenesis** is favored by glucagon by inducing enzymes like PEPCK, glucose-6-phosphatase and fructose-1,6-bisphosphatase.

5. **Glucagon** increases plasma free fatty acid level. In adipose tissue glucagon favors beta-oxidation, as it activates carnitine acyl transferase. The mitochondrial acetyl CoA level increases.

6. **Ketogenesis** is favored.

**Mechanism of action**
Glucagon combines with a membrane bound receptor. This activates the GDP-bound G-protein, by converting it into GTP form (Chapter 44). The alpha subunit of the G protein dissociates from the beta and gamma subunits. The alpha subunit binds to GTP. The GTP-G protein will in turn activate adenylate cyclase to convert ATP to cAMP. Cyclic AMP is the second messenger, which combines with the regulatory subunit of the protein kinase so that the catalytic subunit is free to act. The active protein kinase will phosphorylate enzyme proteins and alter their activity; covalent modification and activation of glycogen phosphorylase, inactivation of glycogen synthase, etc.

**Anti-insulin Hormones**

i. Regulation of carbohydrate metabolism in general depends on balance between insulin and anti-insulin hormones. A summary is given in Box 24.2. See also Table 24.5.

ii. **Glucocorticoids** act mainly by stimulating gluconeogenesis.

iii. But **growth hormone** antagonises insulin in many key metabolic reactions (Table 24.5). Bernado Houssay demonstrated that in pancreatectomised animals, the requirement of insulin was about 100 units per day. When anterior pituitary was also ablated in such animals, the requirement of insulin came down to 10 units or so. This shows that growth hormone antagonises insulin. Houssay was awarded Nobel prize in 1947.

**Diabetes Mellitus**
The term is derived from the Greek words dia (=through), bainein (=to go) and diabetes literally means pass through.

The disease causes loss of weight as if the body mass is passed through the urine. The Greek word, mellitus, means sweet, as it is known to early workers, that the urine of the patient contains sugar. Diabetes mellitus is a disease known from very ancient times. Charaka in his treatise (circa 400 BC) gives a very elaborate clinical description of madhumeha (= sweet urine). He had the vision that carbohydrate and fat metabolisms are altered in this disease. In Western literature, Thomas Willis in 1670 noticed the sweet taste of diabetic urine. In 1838, Bouchardt and Peligot proved that the sugar of diabetic urine is the same as that present in grape sugar. A crude test for urine sugar was first developed by Trommer in 1841. Qualitative test for urine sugar was perfected by Hermann Fehling (1848) and semi-quantitative test by Stanley Benedict (1908). Folin in 1919 identified a method for quantitative determination of sugar in blood.

**Diabetes mellitus** is a metabolic disease due to absolute or relative **insulin deficiency**. Diabetes mellitus is a common clinical condition. About 10% of the total population, and about 1/5th of persons above the age of 50, suffer from this disease. It is a major cause for morbidity and mortality. Insulin deficiency leads to increased blood glucose level. In spite of this high blood glucose, the entry of glucose into the cell is inefficient. Hence, all cells are starved of glucose.

**Criteria for diagnosis** of Diabetes Mellitus are shown in Table 24.1, and under glucose tolerance test. The disease may be classified as follows (WHO recommendation, 1999):

1. **Type 1 Diabetes Mellitus**
(formerly known as **Insulin-dependent** diabetes mellitus; IDDM). About 5% of total diabetic patients are of type 1. Here circulating insulin level is deficient. It is subclassified as:
   a. Immune mediated and
   b. Idiopathic.

2. **Type 2 Diabetes Mellitus**
(formerly known as **non-insulin dependent** diabetes mellitus; NIDDM). Most of the patients belong to this type. Here circulating insulin level is normal or mildly elevated or slightly decreased, depending on the stage of the disease. This type is further classified as:
a. Obese
b. Non-obese
c. Maturity onset diabetes of young (MODY).

3. Diabetic prone states: (a) Gestational diabetes mellitus (GDM); (b) Impaired glucose tolerance (IGT); (c) Impaired fasting glycemia (IFG)

4. Secondary to other known causes: (a) endocrinopathies (Cushing’s disease, thyrotoxicosis, acromegaly); (b) drug induced (steroids, beta blockers, etc.); (c) pancreatic diseases (chronic pancreatitis, fibrocalculus pancreatitis, hemochromatosis, cystic fibrosis).

Type 1 Diabetes Mellitus
i. It is due to decreased insulin production. Circulating insulin level is very low. These patients are dependent on insulin injections. Onset is usually below 30 years of age, most commonly during adolescence. They are more prone to develop ketosis.
ii. An autoimmune basis is attributed to most of these cases. Circulating antibodies against insulin is seen in 50% cases, and antibodies against islet cell cytoplasmic proteins are seen in 80% cases. Type 1 diabetes mellitus is an autoimmune disease in which pathologic, autoreactive T cells of the immune system attack the insulin-secreting pancreatic islets of Langerhans. Cytotoxic T cells, which bear the CD8 protein on their membrane, kill islets, thereby leading to lifelong dependence on insulin for affected patients. Often, a period of poorly controlled blood glucose levels inevitably result in early illness and early death. Insulin and the 65-kD isoform of glutamic acid decarboxylase (GAD) are major autoantigens in patients with type 1 diabetes. GAD is a naturally occurring protein found in the brain and in insulin-secreting islets of the pancreas. It is a self protein that functions as an autoantigen in patients with type 1 diabetes. The self proteins can be subjected to attack not only by autoreactive T cells but also by autoantibodies to GAD. A variety of other autoantibodies, such as the insulinoma-associated–2 autoantibody (IA-2), insulin autoantibody (IAA), and islet-specific glucose-6-phosphatase–related protein (IGRP), are also seen.

Type 2 Diabetes Mellitus
i. 95% of the patients belong to this type. The disease is due to the decreased biological response to insulin, otherwise called insulin resistance. So there is a relative insulin deficiency.
ii. Type 2 disease is commonly seen in individuals above 40 years. These patients are less prone to develop ketosis.
iii. About 60% of patients are obese. These patients have high plasma insulin levels.
iv. The maturity onset diabetes of young (MODY) is due to defective glucokinase (GK). This mutation produces relative insulin deficiency by increasing the threshold for glucose induced insulin secretion. Common MODY3 mutation is in HNF1-alpha. These patients respond to sulphonylurea. When MODY5 mutation is in HNF1-beta, insulin is required.

Metabolic Syndrome (MetS)
The characteristic features are shown in Box 24.6. The hallmarks are abdominal obesity and insulin resistance or decreased glucose tolerance. The body cannot properly use glucose even in presence of normal insulin level. In other words, body cannot use insulin efficiently. Therefore, the metabolic syndrome is also called the insulin resistance syndrome. Syndrome X and cardiometabolic syndrome are other terms used to describe the same condition. People with the MetS are at increased risk of coronary heart disease and type 2 diabetes. The MetS has become increasingly common in the developing countries.

Effects of insulin resistance are: hydrolysis of stored triglycerides or fats, which elevates free fatty acids (FFA) in the plasma; reduction of glucose uptake or glucose utilization among muscle cells and reduction of glycogenesis (glycogen formation) or decreasing glucose storage in the liver cells with both effects leading to elevation of blood sugar levels. In obese patients especially those with high visceral fat, compensatory hyperinsulinemia causes the down regulation of the insulin receptors potentiated by the inherent defects within the target cells itself. Both aspects play a role in the development of insulin resistance.

Box 24.6. Criteria for Diagnosis of Metabolic Syndrome

i. Elevated waist circumference: (For men >90 cm and for women, >80 cm).
ii. Elevated triglycerides: >150 mg/dL
iii. Reduced HDL (“good”) cholesterol: For men, <40 mg/dL; for women, < 50 mg/dL
iv. Elevated blood pressure: >130/85 mm Hg
v. Elevated fasting glucose: >100 mg/dL
vi. Insulin resistance (hyperinsulinemia)
vii. Additional parameters include: coagulation abnormalities, hyperuricemia, microalbuminuria non-alcoholic steatohepatitis (NASH) and increased CRP.
viii. Diagnosis is made, if any 3 out of the 5 criteria given above.
Laboratory tests for MetS: The fasting insulin level greater than 60 pmol/L is considered to be a positive evidence of insulin resistance. Further, hyperinsulinemic euglycemic clamp test may be done in selected cases; however, this is rarely performed in the clinical setting. But this is considered to be the gold standard because it measures the exact amount of glucose necessary to compensate for an increased insulin level without causing hypoglycemia.

Causes for MetS or associated conditions include: obesity; alcoholism; sedentary lifestyle with lack of physical exercise; polycystic ovarian syndrome (PCOS); hypercortisolism (e.g. steroid use or Cushing’s disease); certain drugs such as rifampicin (RIF), isoniazid (INH), progesterone derivatives, antiretrovirals, and genetic causes such as mutations of the insulin receptors.

Polycystic Ovary Syndrome (PCOS) and MetS: They have overlapping features. The common factors are insulin resistance and obesity. In PCOS there is hyperandrogenism. Those with PCOS have an increased risk for coronary vascular disease as in patients with MetS. PCOS may be corrected to some extent by lifestyle modification during the adolescent age by weight reduction and exercise. A higher prevalence of PCOS is seen in women with Type 2 diabetes mellitus. Overweight adolescents with PCOS are at increased risk of developing impaired glucose tolerance and Type 2 diabetes mellitus.

Management of the Metabolic Syndrome
i. Weight loss to achieve a desirable weight.
ii. Moderate exercise every day.
iii. Reduced intake of saturated fats, trans fatty acids and cholesterol.

Metabolic Derangements in Diabetes
The effects of insulin on carbohydrate, lipid and amino acid metabolisms have been described in detail previously (Table 24.4). In diabetes mellitus all these effects are reversed (see Fig. 24.9).

1. Derangements in Carbohydrate Metabolism
Insulin deficiency decreases the uptake of glucose by cells. The insulin dependent enzymes are also less active. Net effect is an inhibition of glycolysis and stimulation of gluconeogenesis leading to hyperglycemia.

2. Derangements in Lipid Metabolism
i. Fatty acid breakdown leads to high FFA levels of plasma and consequent fatty liver.
ii. More acetyl CoA is now available, which cannot be efficiently oxidized by TCA cycle, because the availability of oxaloacetate is limited. The stimulation of gluconeogenesis is responsible for the depletion of oxaloacetate.
iii. The excess of acetyl CoA therefore, is diverted to ketone bodies, leading to ketogenesis (Chapter 11). This tendency is more in Type 1 disease.
iv. There is hyperlipidemia, especially an increase in NEFA, TAG and cholesterol in plasma.

Fig. 24.9. Metabolic derangements in diabetes mellitus
3. Derangement in Protein Metabolism
Increased breakdown of proteins and amino acids for providing substrates for gluconeogenesis is responsible for muscle wasting.

Clinical Presentations in Diabetes Mellitus
Cardinal Symptoms
1. When the blood glucose level exceeds the renal threshold glucose is excreted in urine (glucosuria).
2. Due to osmotic effect, more water accompanies the glucose (polyuria).
3. To compensate for this loss of water, thirst center is activated, and more water is taken (polydypsia).
4. To compensate the loss of glucose and protein, patient will take more food (polyphagia).
5. The loss and ineffective utilization of glucose leads to breakdown of fat and protein. This would lead to loss of weight. Important differential diagnosis for weight loss are diabetes mellitus, tuberculosis, hyperthyroidism, cancer and AIDS.
6. Often the presenting complaint of the patient may be chronic recurrent infections such as boils, abscesses, etc. Any person with recurrent infections should be investigated for diabetes. When glucose level in extracellular fluid is increased, bacteria get good nutrition for multiplication. At the same time, macrophage function of the host is inefficient due to lack of efficient utilization of glucose. In India, tuberculosis is commonly associated with diabetes.

Acute Metabolic Complications
Diabetic Keto Acidosis
Ketosis is more common in type 1 diabetes mellitus. Ketone body formation and explanations for ketosis are described in Chapter 11. Normally the blood level of ketone bodies is less than 1 mg/dl and only traces are excreted in urine (not detectable by usual tests). But when the rate of synthesis exceeds the ability of extrahepatic tissues to utilize them, there will be accumulation of ketone bodies in blood. This leads to ketonemia, excretion in urine (ketonuria) and smell of acetone in breath. All these three together constitute the condition known as ketosis.

Diagnosis of Ketosis
The presence of ketosis can be established by the detection of ketone bodies in urine by Rothera's test. Supportive evidence may be derived from estimation of serum electrolytes, acid–base parameters and glucose estimation.

Rothera's Test: Saturate 5 ml of urine with solid ammonium sulphate. Add a few drops of freshly prepared sodium nitroprusside followed by 2 ml of liquor ammonia along the sides of the test tube. Development of a purple ring indicates the presence of ketone bodies in urine. Strip tests based on the same principle are also available.

Differential Diagnosis of Ketosis
The urine of a patient with diabetic keto acidosis will give positive Benedict's test as well as Rothera's test. But in starvation ketosis, Benedict's test is negative, but Rothera's test will be positive.

Causes for Ketosis
1. Diabetes Mellitus: The combination of hyperglycemia, glucosuria, ketonuria and ketonemia is called diabetic ketoacidosis (DKA). Untreated diabetes mellitus is the most common cause for ketosis. Even though glucose is in plenty, the deficiency of insulin causes accelerated lipolysis and more fatty acids are released into circulation. Oxidation of these fatty acids increases the acetyl CoA pool. Enhanced gluconeogenesis restricts the oxidation of acetyl CoA by TCA cycle, since availability of oxaloacetate is less.
2. Starvation: In starvation, the dietary supply of glucose is decreased. Available oxaloacetate is channeled to gluconeogenesis. The increased rate of lipolysis provides excess acetyl CoA which is channeled to ketone bodies. The high glucagon favors ketogenesis. Hyperemesis (vomiting) in early pregnancy may also lead to starvation-like condition and may lead to ketosis. In both diabetes mellitus and starvation, the oxaloacetate is channeled to gluconeogenesis; so the availability of oxaloacetate is decreased. Hence, acetyl CoA cannot be fully oxidised in the TCA cycle. Oxaloacetate is diverted for gluconeogenesis; then citric acid cycle cannot function optimally. Thus, on the one hand, acetyl CoA is generated in excess; on the other hand, its utilization is reduced. This excess acetyl CoA is channeled into ketogenic pathway (see Fig. 24.9). Ketosis is described in the last part of Chapter 11.

Consequences of Ketosis
i. Metabolic acidosis: Acetoacetate and beta-hydroxy butyrate are acids. When they
accumulate, metabolic acidosis results (see Chapter 29). There will be increased anion gap.

ii. **Reduced buffers**: The plasma bicarbonate is used up for buffering of these acids.

iii. **Kussmaul’s respiration**: Patients will have typical acidic breathing due to compensatory hyperventilation.

iv. **Smell of acetone** in patient's breath.

v. **Osmotic diuresis** induced by ketonuria may lead to dehydration.

vi. **Sodium loss**: The ketone bodies are excreted in urine as their sodium salt, leading to loss of cations from the body.

vii. **High potassium**: Due to lowered uptake of potassium by cells in the absence of insulin.

viii. **Dehydration**: The sodium loss further aggravates the dehydration.

ix. **Coma**: Hypokalemia, dehydration and acidosis contribute to the lethal effect of ketosis.

### Chronic Complications of Diabetes Mellitus

1. **Vascular Diseases**: Atherosclerosis in medium-sized vessels, **plaque formation** and consequent intravascular thrombosis may take place. If it occurs in cerebral vessels, the result is paralysis. If it is in coronary artery, myocardial infarction results. In the case of small vessels, the process is called **micro-angiopathy**, where endothelial cells and mural (cement) cells are damaged. Amyloglycans are deposited in mural cells, so that cementing ability is lost. This leads to micro angiopathy, which may lead to diabetic retinopathy and nephropathy.

2. **Complications in Eyes**: Early development of **cataract** of lens is due to the increased rate of sorbitol formation, caused by the hyperglycemia. Retinal microvascular abnormalities lead to **retinopathy** and blindness.

3. **Neuropathy**: Peripheral neuropathy with paresthesia is very common. Decreased glucose utilization and its diversion to sorbitol in Schwann cells may be caused for neuropathy. Another reason proposed is the production of advanced glycation end products. Neuropathy may lead to risk of foot ulcers and gangrene. Hence, care of the feet in diabetic patients is important.

4. **Kimmelstiel-Wilson syndrome** is another complication of diabetes, resulting from nephrosclerosis, characterized by proteinuria and renal failure. Persistent hyperglycemia leading to glycation of basement membrane proteins may be the cause of nephropathy.

5. **Pregnancy**: Diabetic mothers tend to have big babies, because insulin is an anabolic hormone. Chances of abortion, premature birth and intrauterine death of the fetus are also more, if the diabetes is not properly controlled.

### Management of Ketosis

1. Parenteral administration of insulin and glucose by intravenous route to control diabetes.

2. Intravenous bicarbonate to correct the acidosis.

3. Correction of water imbalance by normal saline.

4. Correction of electrolyte imbalance. Insulin induces glycogen deposition, and along with that, extracellular potassium is distributed intracellularly. This leads to dangerous hypokalemia, which is to be immediately corrected.

5. Treatment of underlying precipitating causes, such as infection.

### Hyperosmolar Nonketotic Coma

It can result due to elevation of glucose to very high levels (900 mg/dl or more). This would increase the osmolality of extracellular fluid (ECF). Osmotic diuresis leads to water and electrolyte depletion. The coma results from dehydration of cerebral cells due to hypertonicity of ECF.

### Lactic Acidosis

It is another acute complication. It occurs due to over production and or under utilization of lactic acid. Overproduction can result from an increased rate of anaerobic glycolysis due to hypoxia. Under utilization may be due to impairment of TCA cycle. Lactic acidosis is seen when diabetic patients are treated with biguanides. This drug inhibits TCA cycle and gluconeogenesis (see Box 24.7).
Laboratory Investigations in Diabetes
Random blood sugar estimation and oral glucose tolerance tests are used for the diagnosis (Table 24.1).

1. Plasma glucose level
For monitoring a diabetic patient, periodic check of fasting and postprandial plasma glucose are to be done at least once in 3 months. Plasma glucose level has to be maintained within the normal limits. Persistent hyperglycemia is the most important factor, which leads to chronic complications.

2. Complete lipid profile
Total cholesterol, triglycerides, HDL and LDL cholesterol levels may be done once in six months (Chapters 12 and 25).

3. Kidney function tests
Blood urea and serum creatinine may be done at least twice an year (Chapter 27).

4. Micro-albuminuria and frank albuminuria
Presence of albumin (50 to 300 mg/day) in urine is known as micro-albuminuria (Chapter 27). It is a predictor of progressive renal damage. Albumin more than 300 mg/day indicates overt diabetic nephropathy. Microalbuminuria is to be checked at least once in an year.

5. Glycated Hemoglobin
   i. The best index of long-term control of blood glucose level is measurement of glycated hemoglobin or glyco-hemoglobin.
   ii. Enzymatic addition of any sugar to a protein is called "glycosylation", while non-enzymatic process is termed "glycation".
   iii. When there is hyperglycemia, proteins in the body may undergo glycation. It is a non-enzymatic process. Glucose forms a Schiff base with the N-terminal amino group of proteins (Fig. 24.10). This is reversible. Later, Amadori rearrangement takes place to form ketoamines, when the attachment becomes irreversible. The overall reaction is called Maillard reaction.
   iv. When once attached, glucose is not removed from hemoglobin. Therefore, it remains inside the erythrocyte, throughout the life span of RBCs (120 days) (Fig. 24.11).
   v. The glycated hemoglobins are together called HbA1 fraction. Out of this 80% molecules are HbA1c, where glucose is attached to the N-terminal valine of beta chain of hemoglobin. The rest of molecules are HbA1a, where fructose-1,6-bisphosphate and HbA1a2, where glucose-6-phosphate are attached. When glycation takes place at the internal lysine residues of alpha or beta chains, it is called HbA1d. All the HbA1 groups are fast hemoglobins, having increased electrophoretic mobility. Routine clinical assays are carried out by chromatography. The positively charged normal hemoglobins will attach to the negatively charged resins; but HbA1, where the charge is masked by the glucose, will come out of the column. The eluted fraction is quantitated, and expressed as a fraction of the total hemoglobin. Nowadays, simple immunoturbidometric method is commonly employed for glyco-Hb estimation.

Interpretation of Glyco-Hb Values
   i. The determination of glycated hemoglobin is not for diagnosis of diabetes mellitus; but only for monitoring the response to treatment. The Hb A1c level reveals the mean glucose level over the previous 10-12 weeks. It is unaffected by recent food intake or recent changes in blood sugar levels. The estimation should be done at least every 3 months in all diabetic patients.
   ii. Normally the level of Hb A1c is less than 6%. The value 6% denotes very good control of diabetes by treatment measures; 7% means adequate control; 8% inadequate control and 9% means very poor control. Any value above 6% is to be closely watched and values between 6.5 and 7 are to be considered as impaired glucose tolerance.
   iii. Based on the results of the A1c-Derived Average Glucose (ADAG) value study, it is
recommended to express the values as estimated average glucose, or eAG. This method is intended to help health care providers report HbA1c results to patients using the same units (mg/dl) that patients see routinely in blood glucose measurements. Thus, HbA1c value of 6% represents average glucose level of 126 mg/dl; 7% means 154 mg; 8% means 183 mg; 9% means 212 mg; and Hb1Ac 10% equals 240 mg/dl.

iv. An elevated glycohemoglobin indicates poor control of diabetes mellitus. The risk of retinopathy and renal complications are proportionately increased with elevated glycated hemoglobin value. Reduction in 1% of glycoHb will decrease long-term complications to an extent of 30%. Fluctuations of HbA1c are postulated to be responsible for long-term complications of diabetes like retinopathy and nephropathy.

v. HbF also behaves similar to HbA1c in the separating column. So, abnormally high values may be seen even in normal children, as well as persons with thalassemia. On the other hand glycated HbS and glyco-HbC are retained in the column, and so abnormal low values are obtained in persons with HbS and HbC, even though they have diabetes. Lowered values are also seen in hemolytic anemias due to shortened life span of red blood cells, when time averaged value is lesser. These false results are generally eliminated by the newer immunoturbidometric measurements.

Fructosamines
Along with other proteins, albumin is also glycated in diabetes mellitus. Glycated albumin is more correctly called as fructosamino albumin. As half-life of albumin is about 20 days, gluco-albumin concentration reflects the glucose control over a recent past, for a period of last 2-3 weeks. Estimation of serum fructosamine is preferred in gestational diabetes mellitus.

Fructose participates in glycation 10 times faster than glucose. High fructose levels are related to aging and myocardial infarction.

Advanced Glycation End Products (AGEs)
These are found in the tissues of diabetic patients. Such glycation of matrix proteins, when once occurred, is completely irreversible. Glycation of collagen alters the properties, cross linking is increased and elasticity of collagen is lost. Adhesion of plasma proteins in the altered blood vessels leads to accumulation of LDL, and consequent atherosclerosis. In diabetic vascular tissues the concentration of AGEP is four times that of normals. Microvascular damage in diabetes is attributed to AGEs. Uptake of AGEs by macrophages will lead to production of inflammatory cytokines. Study reveals that increased AGEPs are associated with oxidative stress in the elderly groups. Such AGEP formation might have a role in cataract formation, which, in diabetic patients, occurs more commonly as compared with non-diabetic cataract patients. The rate of formation of AGEs is proportional to the square of glucose concentration. Excessive formation and accumulation of AGEs lead to cross linking of extracellular proteins, altered matrix interactions and modification of DNA structure and function. Aminoguanidine is an inhibitor of the formation of AGEs; this may reduce the complications of diabetes mellitus.

Management of Diabetes Mellitus
1. Diet and Exercise: This is the first line of treatment. A diabetic patient is advised to take a balanced diet with high protein content, low calories, devoid of refined sugars and low saturated fat, adequate PUFA, low cholesterol and sufficient quantities of fiber. Vegetables are the major sources of minerals, vitamins and fiber. Low-carbohydrate ketogenic diet (LCKD) was found to be quite promising in controlling diabetes mellitus. LCKD has a significant beneficial effect in ameliorating the diabetic state and helping to stabilize hyperglycemia.

2. Oral hypoglycemic agents: They are mainly of two types; sulphonyl urea and biguanides. They are mainly used in Type 2 diabetes.

3. Insulin injections: Insulin is the drug of choice in Type 1 disease. It is also used in Type 2 disease, where oral drugs are not sufficient.

Hypoglycemia
Hyperglycemia causes harm; but hypoglycemia is fatal. A fall in plasma glucose less than 50 mg/dl is life-threatening. Causes of hypoglycemia are:

1. Overdose of insulin: This is the most common cause. The differentiation of hypoglycemic coma from hyperglycemic coma (ketosis) is important, since treatment is exactly opposite. The diagnosis is mainly based on blood glucose estimation.

2. Post-prandial hypoglycemia: 2-3 hours after a meal, transient hypoglycemia is seen in some persons. This is due to over-secretion of insulin.

3. Insulinoma: Insulin secreting tumors are rare.

4. Von Gierke's disease (Chapter 9).
CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:
1. Hypolipoproteinemias
2. Hyperlipidemias
3. Atherosclerosis and coronary artery disease
4. Risk factors for coronary artery disease
5. Prevention of atherosclerosis

Clinical Significance of Cholesterol

Students should be familiar with cholesterol and lipoproteins described in detail in Chapter 12. A summary of lipoproteins is given in Table 25.1 and their metabolic relationships are shown in Fig. 25.1. LDL is said to be "bad" cholesterol and HDL is "good" cholesterol (Fig. 25.2). The level of cholesterol in blood is related to the development of atherosclerosis. Abnormality of cholesterol metabolism may lead to cardiovascular accidents and heart attacks.

ATHEROSCLEROSIS

Greek word, sclerosis means hardening. Coronary artery obstruction and myocardial infarction are the number one killers in the world. In India, 20% deaths are due to coronary artery disease (CAD). It is estimated that by the year 2020, it will account for 33% of all deaths.

Atherosclerosis and LDL

Stage I: Formation of foam cells: Increased levels of cholesterol for prolonged periods will favor deposits in the subintimal region of arteries. Aorta, coronary arteries and cerebral vessels are predominantly affected by the atherosclerotic process. The LDL cholesterol, especially oxidized

LDL particles are deposited in the walls of arteries. Plasma LDL is mainly catabolised via apo-B-LDL receptor pathway. But a small part of LDL particles is degraded by nonspecific uptake of macrophages. Free radical induced oxidative damage of LDL will accelerate this process. Later, the macrophages become overloaded with cholesterol, and these are then called foam cells. These form the hallmark of atherosclerotic plaques.

**Stage II: Progression of atherosclerosis:** Smooth muscle cells containing lipid droplets are seen in the lesion. During early stages of atherosclerosis, the condition is reversible if plasma lipid levels, especially LDL-cholesterol levels are lowered. But when lipid is accumulates, the lesion progresses unchecked and the arterial changes become irreversible.

**Stage III: Fibrous proliferation:** Due to liberation of various growth factors by macrophages and platelets, lipoproteins, glycosaminoglycans and collagen are accumulated. Thus there is a definite component of inflammation in atherosclerosis. This chronic inflammation leads to increased plasma high sensitive C-reactive protein (hs-CRP) (see Chapter 28).

**Stage IV: Advancing fibrous plaque:** This leads to narrowing of vessel wall when proliferative changes occur (Fig. 25.3). The blood flow through the narrow lumen is more turbulent and there is tendency for clot formation.

**Myocardial Infarction (MI)**
A clot is formed which occludes one of the major vessels. Thrombosis in coronary artery leads to ischemia of cardiac tissue supplied, due to hindrance to oxygen supply (Fig. 25.3). Finally infarction (death of tissue) occurs (Fig. 25.4). Along with this ischemia (decreased blood supply), instead of the normal aerobic conditions, anaerobic glycolysis takes place.

**Box 25.1. Clinical Conditions in which Serum Cholesterol Level is Increased**

1. **Diabetes mellitus:** Acetyl CoA pool is increased and more molecules are channelled to cholesterol.
2. **Obstructive jaundice:** The excretion of cholesterol through bile is blocked.
3. **Hypothyroidism:** The receptors for HDL on liver cells are decreased, and so excretion is not effective.
4. **Nephrotic syndrome:** Albumin is lost through urine, globulins (including lipoproteins) are increased as a compensatory mechanism.
5. **Familial hyperlipoproteinemias:** See Frederickson’s classification (Table 25.4).

---

**Fig. 25.2.** Forward and reverse transport of cholesterol

**Fig. 25.4.** Thrombosis in the artery leads to infarction of the area supplied by the artery
Box 25.2. When should we Check Lipid Profile?
1. Suspected cardiovascular disease, coronary artery disease and peripheral vascular disease
2. All patients with diabetes mellitus, at least once in 6 months.
3. Thyroid, liver and renal diseases, where lipid metabolism may be altered.
4. All persons above 40 should be checked for once in a year.

Box 25.3. Risk Factors for Cardiovascular Disease

Class 1: Modifiable risk factors, interventions have been proved to lower CAD risk.
- Cigarette smoking
- High total cholesterol
- High LDL cholesterol
- Low HDL cholesterol
- Low fat/cholesterol diet
- Left ventricular hypertrophy (LVH)
- Thrombogenic factors

Class 2: Modifiable risk factors, interventions are likely to lower CAD risk.
- Lipoprotein (a) or Lp(a)
- Diabetes mellitus
- Hypertension
- Physical inactivity
- Obesity
- High triglycerides
- High homocysteine
- Increased high-sensitivity-CRP (hs-CRP)
- Stress

Class 3: Nonmodifiable risk factors.
- Age
- Male gender
- Family history of CAD

PLASMA LIPID PROFILE
The sample of serum should be taken after 12-14 hours of fasting. In laboratories, lipid profile is assessed by estimating the following fractions in plasma:
1. Total cholesterol

<table>
<thead>
<tr>
<th>Table 25.2. CHD risk and lipid parameters</th>

</tr>
</tbody>
</table>

Abnormal levels of serum cholesterol are seen in certain conditions; these are listed in Box 25.1. Box 25.2 gives the indications for checking the lipid profile.

RISK FACTORS FOR ATHEROSCLEROSIS
See Box 25.3. A total cholesterol level below 200 mg/dl; the LDL cholesterol (direct) below 100 mg/dl and a non-HDL cholesterol below 130 mg/dl predicts no risk. The values are different in the presence of other risk factors like obesity, diabetes mellitus, hypertension, smoking, etc. The athero-
protective HDL-cholesterol should be more than 40 mg/dl in males and >50 mg/dl in females.

1. Serum cholesterol level
   i. In 1970s, data from the Framingham epidemiological study demonstrated that increase in serum cholesterol level is associated with an increased risk of death from CHD. For every 10% lowering of cholesterol, CHD mortality was reduced by 13%. Reduction of cholesterol may not only decrease the lipid content of the plaque, but can also reduce the accumulation of monocytes and macrophages.
   ii. In healthy persons, cholesterol level varies from 150 to 200 mg/dl (see Table 25.2). If other risk factors are present, cholesterol level should be kept preferably below 180 mg/dl. Values around 220 mg/dl will have moderate risk and values above 240 mg/dl will need active treatment.
   iii. Females have a lower level of cholesterol which affords protection against atherosclerosis.
   iv. Plasma cholesterol levels would tend to slowly rise after the 4th decade of life in men and post-menopausal women.

2. LDL-cholesterol level
   In 1988, the National Cholesterol Education Program (NCEP) identified elevated LDL-C as a primary risk factor for CHD. Blood levels under 130 mg/dl are desirable (see Table 25.2). Levels between 130 and 159 are borderline; while above 190 mg/dl = Very high risk

3. HDL-cholesterol level
   HDL level above 60 mg/dl protects against heart disease (see Table 25.2). Hence HDL is “good” cholesterol. A level below 40 mg/dl increases the risk of CAD. For every 1 mg/dl drop in HDL, the risk of heart disease rises 3%. If the ratio of total cholesterol / HDL is more than 3.5, it is dangerous. Similarly, LDL:HDL ratio more than 2.5 is also detrimental.

4. Apoprotein levels and ratios
   Apo-A-I is a measure of HDL-cholesterol (good) and apo-B measures LDL-cholesterol (bad). Ratio of Apo-B : A-I is the most reliable index. The ratio of 0.4 is very good; the ratio 1.4 has the highest risk of cardiovascular accidents.

5. Lp(a)
   Lp(a) inhibits fibrinolysis. Levels more than 30 mg/dl increase the risk 3 times; and when increased Lp(a) is associated with increased LDL, the risk is increased 6 times (see Lpa in Chapter 12). Nicotinic acid will reduce serum Lp(a) level.

6. Non-HDL cholesterol
   A value of more than 160 mg/dl carries high risk (see Box 25.4).

7. Cigarette
   Cigarette smoking is the most important modifiable risk factor for CAD (see Box 25.3). Risk from smoking is dose-dependant; depends on the age at which the person started smoking and the number of cigarettes smoked per day. Smoking enhances oxidation of LDL, reduces HDL, increases CRP and augments aggregation and adhesion of platelets.
Nicotine of cigarette will cause lipolysis thereby increasing the acetyl CoA and cholesterol synthesis. Nicotine also causes transient constriction of coronary and carotid arteries.

8. Diabetes mellitus
CVD is responsible for 80% of total diabetic mortality. Diabetes is associated with an increase in small LDL particles, high TG and low HDL levels. In the absence of insulin, hormone sensitive lipase is activated, more free fatty acids are formed, which are catabolised to produce acetyl CoA. These cannot be readily utilised, as the availability of oxaloacetate is reduced and citric acid cycle is sluggish. So acetyl CoA pool is increased, and it is channelled to cholesterol synthesis.

In diabetes, the atherogenicity of LDL is increased while atheroprotective effect of HDL is decreased. In diabetes mellitus, the TAG pool in the cell is high and the LDL particles formed from VLDL are of the small dense variety, that are highly atherogenic. The glycation and oxidation of LDL will delay their catabolism and promote the uptake by macrophages, which is a dysregulated process. At the same time, the level of HDL in diabetic patients and those with metabolic syndrome is low. Glycation of Apo-A1 decreases its ability to stimulate LCAT, and thereby the esterification and efflux of cholesterol from the cells. The antioxidant effect (Paroxonase activity) of HDL is also decreased. The alterations in the level and properties of LDL and HDL together contribute to the increased risk for CAD in diabetes mellitus.

9. Hypertension
Systolic blood pressure more than 160 further increases the risk of CAD. An increase in 10 mm of BP will reduce life expectancy by 10 years. Increase of 5 mm Hg of diastolic pressure is associated with 34% increase in risk for stroke.

10. Obesity and sedentary lifestyle
The classical description of Pickwick (in Pickwick papers) by Charles Dickens reminds of a person with high risk for CAD. People with “apple type” of obesity with a “Ganapathy” belly (truncal obesity) are more prone to get myocardial infarction. A person is obese when BMI exceeds 27.8 kg/m² in men and 27.3 kg/m² in women (excess of 120% of desirable body weight). Obesity is associated with substantially increased cardiovascular risk. Obesity causes glucose intolerance, insulin resistance, hypertension and dyslipidemia.

11. Serum triglyceride
Normal level is 50-150 mg/dl. Blood level more than 150 mg/dl is injurious to health.

12. Homocysteine level
Plasma homocysteine above 15 micromol/L will increase the risk of coronary artery disease and stroke at a younger age. Administration of pyridoxine, vitamin B₁₂ and folic acid may lower the homocysteine level.

13. High sensitivity C-reactive protein
Increased hs-CRP in blood is a predictor of future coronary events among apparently healthy persons.

14. Long chain saturated fatty acids (e.g. stearic acid) induces pro-inflammatory responses and significantly impedes growth and viability of endothelial cells. They have harmful effects on the vascular system. Medium chain saturated fatty acids (C₆:₀ to C₁₂:₀) do not significantly affect endothelial cell growth.
Chapter 25: Cardiovascular Diseases and Hyperlipidemias

PREVENTION OF ATHEROSCLEROSIS

Almost 90% of CAD is predictable, preventable and curable. Lifestyle changes are required, which include regular exercise, balanced diet, cessation of smoking, maintaining proper weight, control of hypertension, diabetes and dyslipidemia. The aim is to reduce total cholesterol below 180 mg/dl; to decrease LDL-cholesterol below 130 mg/dl and to keep HDL-cholesterol above 35 mg/dl (see Box 25.5).

1. Reduce dietary cholesterol
Cholesterol in the diet should be kept less than 200 mg per day. Eggs and meat contain high cholesterol. One egg yolk contains about 500 mg of cholesterol (Fig. 25.5A). One double omelet increases the blood cholesterol 15 mg more than the original level.

2. Vegetable oils and PUFA
Vegetable oils (e.g. sunflower oil) and fish oils contain polyunsaturated fatty acids (PUFA). They are required for the esterification and final excretion of cholesterol. So PUFA is helpful to reduce cholesterol level in blood (Fig. 25.5B). **Omega-3 fatty acids** from fish oils reduce LDL and decrease the risk of CAD. Recommended intake of omega-3 fatty acid (fish oils) is 1 g/day (EPA and DHA combined).

3. Moderation in fat intake
The accepted standard is that about 20% of total calories may be obtained from fat, out of which about one-third from saturated, another one-third from mono-unsaturated and the rest one-third from poly unsaturated fatty acids. The recommended daily allowance will be about 20-25 g of oils and about 2-3 g of PUFA per day for a normal adult.

4. Green leafy vegetables
Due to their **high fiber content**, leafy vegetables will increase the motility of bowels and reduce reabsorption of bile salts (Fig. 25.6). Vegetables also contain plant sterols (**sitosterol**) which decrease the absorption of cholesterol. About 400 g/day of fruit and vegetables are desired.

5. Avoid sucrose and cigarette
Cigarette smoking is the most important modifiable risk factor for CAD (see Box 25.3). Sucrose will raise plasma triglycerides. High carbohydrate diet, especially sucrose, should be avoided by patients with hypercholesterolemia.

6. Exercise
Regular moderate exercise (30 min per day) will lower LDL (bad cholesterol) and raise HDL (good cholesterol) levels in blood. It will also reduce obesity. Individuals spending more than 2000 kcal/week in exercise are at a lower risk. Individuals who walked less than 1.5 km per day had a 2.6 times greater risk for CHD death, and 2.4 times greater risk for cancer.

7. Hypolipidemic drugs
   i. **HMGCoA reductase inhibitors** ("statins"): Atorvostatin and Simvostatin are popular drugs in this group. They are effective in reducing the cholesterol level and decreasing the incidence of CAD (see Box 25.6 and 25.7).
   ii. **Bile acid binding resins** (Cholestyramine and Cholestipol) decrease the reabsorption of bile acids (see Box 25.7).
   iii. **Probucol** increases LDL catabolism and prevents accumulation of LDL in arterial walls.

---

**Box 25.6. When to Start Statins?**

1. All patients with established cardiovascular disease (secondary prevention).
2. Patients with diabetes mellitus, especially over 40 years of age.
3. Diabetes mellitus with other risk factors such as retinopathy, nephropathy, microalbuminuria, hypertension.
4. Total cholesterol above 220 mg/dl or LDL more than 160 mg/dl or Total cholesterol : HDL ratio more than 6.
5. Family history of premature CVD.
6. Lifestyle alterations (exercise and diet) are not enough to reduce the cholesterol level.

**Box 25.7. Expected Effect of Drug Therapy**

So more cholesterol will be converted to bile acids, thus reducing the cholesterol level.

iv. Nicotinic acid inhibits lipolysis and so VLDL level is decreased. Nicotinic acid reduces plasma cholesterol and decreases serum Lp(a) levels.

v. Ezetimibe is a drug which selectively inhibits absorption of cholesterol from mixed micelle (Box 25.8).

vi. Aspirin is widely used to prevent thrombus formation, because of its anti-platelet activity (see Chapter 13).

vii. Anti-oxidants such as vitamin E will minimise oxidation of LDL and so, atherosclerosis may be reduced.

viii. Plant-derived products having cholesterol-lowering action are enumerated in Box 25.8.

8. Avoid trans fatty acids (TFA)

Trans fatty acids (with double bonds having trans configuration) are formed during the partial hydrogenation of vegetable oils. They are widely used in food industry because of their long shelf life. Trans fatty acids (TFA) are found to be more atherogenic than saturated fatty acids. TFA will alter the membrane fluidity. TFA is also implicated in modulating metabolism. It alters secretion and composition of apo-B-100 containing lipoproteins (LDL and VLDL). It increases catabolism of apo-A-I, decreases HDL and increases LDL levels. Hence Federal Drug Agency (FDA) in USA stipulates that TFA content of food items be given on the labels. Reducing the intake of TFA to 2-7 g/day is now strongly advised.

Clinical studies have suggested that DHA, (docosa hexaenoic acid) and EPA, (eicosa pentaenoic acid) lower triglycerides; slow the buildup of atherosclerotic plaques; as well as reduce the risk of heart attack and arrhythmias.

### Box 25.8. Plant-derived Products having Cholesterol-lowering Action

- **Plant-derived fiber**: Reduces serum cholesterol
- **Legumes**: Reduces cholesterol even on high fat diet
- **Onion and garlic**: Reduce serum cholesterol and TG
- **Embelia ribes (vidanga)**: Dried berries alone or along with amla has hypolipidemic effect
- **Commiphora mukul (guggulu)**: Hypolipidic and cardioprotective
- **Cyperus rotundus (musta)**: Hypolipidemic; improves metabolic activity
- **Spices, flavinoids, red wine**: Natural antioxidants prevent oxidative modification of LDL

**PUFA, in excess, may be harmful**

PUFA can definitely reduce cholesterol level. But there should be moderation. It is known that the diet should contain correct type and quantity; the optimum ratio of omega-6 to omega-3 fatty acids is 4:1. Very high intake of omega-6 oils will cause lowering of HDL, elevation of plasma triglycerides, and will promote platelet aggregation. Vegetable oils (sunflower oil), containing PUFA are rich in omega-6 variety; while ghee and butter are low in omega-6. Omega-3 group is present in fish oils. Normal Indian diet consisting of cereals, pulses and vegetables provides “invisible oils”, which contains about 10 g of PUFA/day (out of which about 2 g is omega-3 and the rest 8 g is omega-6). Further intake of omega-6 oils is unnecessary and may be harmful.

The optimal ratio for omega-6 to omega-3 in diet is 4:1. In an average Indian diet, this is about 30:1. In sunflower oil, this value is 160:1, and therefore, unnecessary addition of such vegetable oils will further deteriorate the condition. Coconut oil, although contains saturated fatty acids, the
The omega ratio is 3:1, and therefore, superior to sunflower oil in this respect.

The general advice against the use of ghee and coconut oil needs re-evaluation. This mis-information arose, when long chain saturated fatty acids (LCSFA) were shown to increase cholesterol level. Since butter and coconut oil also contain saturated fatty acids, people equated them with LCSFA. Now it is known that ghee and coconut oil contain small chain (SCFA) and medium chain fatty acids. The differences in metabolisms of LCFA and SCFA are given in Chapter 13. In summary, ghee and coconut oil, within normal limits, neither decrease nor increase cholesterol levels. But it is to be noted that consumption of ghee (any oil in general), increases the total fat intake as well as calorie intake. That is harmful. Again, moderation is the key.

HYPOLIPOPROTEINEMIAS

1. Abeta lipoproteinemia
All apo-B containing lipoproteins are reduced since microsomal triglyceride transfer protein is defective. Hence TAG is not incorporated into VLDL and chylomicrons (Table 25.3). Beta lipoprotein (LDL) is absent. Fat-soluble vitamins are not absorbed, causing mental and physical retardation. Serum levels of triglycerides, cholesterol and phospholipids are extremely low. Blindness may occur as a result of degenerative changes in retina. Erythrocytes have spiny projections (acanthocytes).

2. Hypo alpha lipoproteinemia
This is inherited as an autosomal dominant trait. Serum HDL is decreased. There is increased risk for coronary artery diseases (Table 25.3).

3. Tangier disease
It was first described in patients from Tangier island in North-West Africa. It is a relatively rare, autosomal dominant condition. It is characterised by a defect in the efflux (flowing out) of cholesterol from cells, and reduction of HDL levels in the blood. The biochemical defect is the absence of “ATP-Binding Cassette Transporter-1” (ABC-1), which is involved in transferring cellular cholesterol to HDL. So, plasma HDL is low and alpha band is not prominent in electrophoresis. Cholesterol esters are accumulated in tissues. Manifestations are large orange yellow tonsils, muscle atrophy, recurrent peripheral neuropathies and atherosclerosis.

HYPERLIPIDEMIAS

The most widely accepted Frederickson's classification is shown in Table 25.4. In all cases of hyperlipidemias, the elevated lipid fraction is either cholesterol or TAG or both. Hence from a clinical and therapeutic point of view, hyperlipidemias are classified into, hypercholesterolemia (Type IIa), hypertriglyceridemia (Type I, IV and V) and combined hyperlipidemia (Type IIb and Type III).
The elevation of lipids in plasma leads to the deposition of cholesterol on the arterial walls, leading to atherosclerosis (see under Coronary Artery Diseases). The coronary and cerebral vessels are more commonly affected. Thromboembolic episodes in these vessels lead to ischemic heart disease and cerebrovascular accidents.

The deposition of lipids in subcutaneous tissue leads to xanthomas. The type of xanthoma depends on the nature of lipid deposited. Eruptive xanthomata are small yellow nodules associated with deposition of triglycerides. They disappear when the lipid level falls. Tuberous xanthomata are yellow plaques containing triglycerides and cholesterol, found mainly over the elbows and knees. Xanthelasma are lipid deposits under the periorbital skin and contain mainly cholesterol. Tendinous xanthomata are found over the tendons. Deposits of lipids in cornea lead to corneal arcus; indicating hypercholesterolemia.

Hyperlipidemias, in the order of highest to lowest incidence, are described below.

### Type II A
*Primary familial hypercholesterolema*

There is elevation of LDL. Patients seldom survive the second decade of life due to ischemic heart disease (Table 25.4). The cause is LDL receptor defect. Receptor deficiency in liver and peripheral tissues will result in the elevation of LDL levels in plasma, leading to hypercholesterolemia. The LDL receptor defect may be due to the following reasons:

1. **LDL receptor deficiency.**
2. **Defective binding** of B-100 to the receptor. A substitution of glutamine for arginine at 3500th amino acid results in poor binding to LDL receptors. This defect is known as B-3500 or familial defective apo-B.

3. **Receptor-LDL complex is not internalised.**
   - Secondary type II hyperlipoproteinemia is seen in hypothyroidism, diabetes mellitus, nephrotic syndrome and cholestasis (Table 25.5).

### Type II B hyperlipoproteinemia

There is elevation of both cholesterol and triglycerides with excessive production of apo-B. Therefore, LDL and VLDL are elevated. The abnormalities are manifested only by the third decade of life.

### Type IV (familial endogenous type)

This is due to overproduction of triglycerides by liver. The VLDL level in plasma is elevated. Cardiac manifestations are seen in the 4th decade of life. It may be associated with diabetes mellitus, obesity and impaired glucose tolerance.

### Type I

It is rare. It is due to lipoprotein lipase deficiency. It usually manifests in young age. A chylomicron band in fasting plasma is the characteristic finding. Hepatomegaly, eruptive xanthoma and abdominal pain are seen (Table 25.4).

### Type III

It is very rare. It is due to increased levels of LDL and IDL. Beta lipoprotein floats on ultra-centrifugation and a broad beta band is observed on electrophoresis (see Table 25.4). Palmar xanthomas and vascular disease are noticed.

### Type V

Chylomicrons and VLDL are increased. Hypertriglyceridemia, usually secondary to other disorders like obesity, excessive alcohol intake, renal failure, pancreatitis, etc. are common (see Table 25.5). Other causes of hyperlipoproteinemias include hepatic lipase defect, LCAT defect and Lp(a) excess and Wolman’s disease (Table 25.6).

Table 25.5. Secondary hyperlipidemias

Table 25.6. Minor causes for hyperlipoproteinemias
Biochemical tests are of immense value in diagnosis and monitoring of liver diseases. These tests are usually referred to as “liver function tests” (LFT). LFTs are the most widely performed biochemical tests in the laboratory. Important liver functions are listed in Table 26.1. Often abnormal liver function will lead to jaundice (Fig. 26.1).

A long list of tests was formerly included under this group. They were classified based on the major functions of liver. (1) Excretion of bile pigments, bile salts, BSP (Bromsulphthalein) and ICG (Indocyanine green). (2) Metabolism of carbohydrates and amino acids. (3) Synthesis of serum proteins, especially albumin and prothrombin. (4) Detoxification of ammonia and hippuric acid synthesis. (5) Serum enzymes, acting as markers of liver damage.

But nowadays, only clinically useful tests are being done. These liver function tests are broadly classified as:

1. Tests to detect hepatic injury:
   a. To detect the disease, whether mild or severe; whether acute or chronic.
   b. To assess the nature of liver injury; hepatocellular or cholestasis.

2. Tests to assess hepatic function.

Problems in interpretation
a. Normal LFT values need not indicate absence of liver disease, because liver has very large reserve capacity.

b. Asymptomatic people may have abnormal LFT results. So interpretation should be based on clinical picture.

**Box 26.1. Major Functions of Liver**

1. Synthetic function
   a. Synthesis of plasma proteins (albumin, coagulation factors, many globulins)
   b. Synthesis of cholesterol
   c. Synthesis of triacyl glycerol
   d. Lipoprotein synthesis

2. Metabolic function
   a. Carbohydrates: glycolysis; glycogen synthesis; glycogen breakdown; gluconeogenesis
   b. Ketogenesis; fatty acid synthesis and breakdown
   c. Protein catabolism
   d. Citric acid cycle, production of ATP

3. Detoxification and excretion
   a. Ammonia to urea
   b. Bilirubin (bile pigment)
   c. Cholesterol
   d. Drug metabolites

4. Homeostasis: Blood glucose regulation

5. Storage function: Vitamin A, D, K, B12

6. Production of bile salts; help in digestion
Box 26.2. Pathogenesis of Ascites

- Scarring of liver
- Increased resistance to blood flow
- Hypoalbuminemia, leading to decreased colloid intravascular pressure, oozing of protein-rich fluid into the intraperitoneal space, increased intraperitoneal colloid pressure
- Decreased central blood pressure
- Decreased renal perfusion, leading to activation of renin angiotensin system, sodium retention, water retention
- Further fluid escapes into the peritoneal cavity

Carbohydrate Metabolism
Glucose may be metabolized through glycolysis, and then to citric acid cycle and oxidative phosphorylation to yield energy, if the cells are in need of ATP. If not, glucose can be stored as glycogen within the liver or it can be converted into more stable storage form as triglycerides. Homeostasis of blood glucose is described in Chapter 24.

Amino Acid Metabolism
Proteins break down in the intestine and absorbed as amino acids which then reach liver by portal vein. There they may be utilized to form proteins of different kinds. Some of them are produced only in the liver, examples are albumin, alpha and beta globulins and coagulation factors I, II, V, VII, IX and X (see Box 26.1). Several proteins of acute phase reaction are produced in the liver, e.g. C-reactive protein (inflammatory diseases).

Lipid Metabolism
Fatty acids will be catabolized to release acetyl CoA. It may be used in the TCA cycle and ETC to release energy or to act as a source of carbon for fatty acid and cholesterol synthesis in healthy individuals. A small portion of acetyl CoA is converted to ketone bodies (acetone, acetoacetic acid and beta hydroxy butyric acid). Dietary lipids are repackaged and secreted into the systemic circulation as lipoproteins. The protein parts of the lipoproteins, apoproteins are synthesized by the liver only. Hence the liver has an important role in the distribution of lipids in the body. Lipoproteins are described in Chapter 12.

Bilirubin Metabolism
The heme present in the hemoglobin and other proteins/enzymes (e.g. cytochromes) are eliminated only through liver (Chapter 21). The lysis of red blood cells releases hemoglobin which splits to release globin and heme. The heme part is catabolized by microsomal heme oxygenase system of reticulo-endothelial system to produce bilirubin. The bilirubin (unconjugated) thus formed is hydrophobic in nature hence it is transported in the blood by binding with albumin to reach the liver. In the liver, it is conjugated with glucuronic acid to form hydrophilic conjugated bilirubin and is excreted in bile into the intestine. Bacterial action (deconjugation and reduction) forms bilinogens (stercobilinogen, mesobilinogen and urobilinogen). About 20% of the urobilinogen is reabsorbed daily from the intestine to enter enterohepatic circulation to get re-excreted into the intestinal lumen (enterohepatic circulation). A small fraction of urobilinogen enters the systemic circulation and gets filtered at the glomerulus and excreted in urine.

Detoxification Functions
Liver plays a central role in detoxifying reactions.

- **Exogenous substances**: Toxic substances entering from gut and parenteral route are mainly detoxified in the liver by different reactions like hydrolysis, hydroxylation, oxidation, carboxylation, reduction and demethylation. The detoxified products are more water soluble and thus easily excreted in urine. The cytochrome P450 enzyme system of hepatocyte is mainly concerned with drug metabolism; conversion of drugs into more soluble forms which in due course conjugate with compounds like glycine, glucuronic acid and glutathione and finally excreted either in urine or through bile.

Endogenous substances: Disposal of bilirubin is already discussed. Ammonia produced from amino acid catabolism is detoxified by the liver to form less toxic urea. The key urea cycle enzymes are located entirely in liver.

Excretory Functions
Substances detoxified by the liver are excreted through bile. About 3 liters of bile is produced daily and out of this 1 liter is excreted and the rest is reabsorbed and circulated in the enterohepatic circulation. The bile contains bile salts, conjugated bilirubin, phospholipids and hormones. Bile acids/bile salts form the major route of cholesterol excretion. The bile reaching the intestine facilitates the digestion and absorption of lipids and fat-soluble vitamins. Major functions of the liver are summarised in Box 26.1.

Clinical Manifestations of Liver Dysfunction
Jaundice
Jaundice is the yellowish discoloration of sclera, skin and mucus membrane. It is characteristic of liver disease but it will occur. When rate of hemolysis is increased leading to elevation of serum bilirubin.

Portal Hypertension
The entire venous drainage of gastrointestinal tract, the spleen, the pancreas and the gallbladder constitutes portal circulation with a pressure of 5 mm of Hg. Any obstruction in the course of portal circulation will cause portal hypertension. Causes:

a. Presinusoidal – e.g. portal vein thrombosis
b. Sinusoidal – cirrhosis
c. Postsinusoidal – hepatic vein thrombosis
Effects of portal hypertension are:
- a. Due to increase in pressure, veins of portal system get dilated (varices). Liver becomes more dependent on arterial blood flow from hepatic artery.
- b. Portosystemic shunting leads to deterioration of the metabolic functions of the liver.
- c. Hyper-estrogenism is manifested as testicular atrophy, gynecomastia and palmar erythema.
- d. Failure of detoxification of ammonia by urea synthesis leads to hyperammonemia and hepatic encephalopathy.
- e. Decrease in albumin synthesis leads to hypoalbuminemia which predispose to oozing of fluid into the peritoneal cavity causing ascites.
- f. Diminished synthesis of clotting factors predisposes to bleeding.
- g. Loss of thrombolytic factors (e.g. antithrombin III) predisposes to hypercoagulability and venous thrombosis.

Ascites
It is due to effusion of serous fluid into the abdominal cavity. It is a common presenting feature of cirrhosis. Most often it accompanies peripheral edema. Ascites may be due to causes not related to any pathology of liver. The biochemical parameter useful to differentiate ascites resulting from portal hypertension and other causes of ascites is the ratio of serum albumin: ascitic fluid albumin. If it is > 1.1, it is diagnostic of portal hypertension as the cause. Box 26.2 explains the pathogenesis of ascites. Box 26.3 gives the indications of liver function tests. A detailed classification of the liver function tests (LFT) is shown in Table 26.1. Important liver function tests are described below:

### I. Markers of Hepatic Dysfunction

#### 1. Measurement of Bilirubin

**Test of excretory function of liver**
Bilirubin is the excretory product formed by the catabolism of heme. It is conjugated by the liver to form bilirubin diglucuronide and excreted through bile (see Chapter 21). Measurements of bilirubin as well as detection of bilirubin and urobilinogen in urine are important tests of liver function.

- i. Normal serum bilirubin level varies from 0.2 to 0.8 mg/dl. The unconjugated bilirubin (bilirubin-albumin complex) (free bilirubin) (indirect bilirubin) varies from 0.2–0.7 mg/dl and conjugated bilirubin (direct bilirubin) 0.1–0.4 mg/dl. A rise in serum bilirubin above 1 mg/dl is abnormal (latent jaundice); but jaundice appears only if the level goes above 2 mg/dl.
ii. The bilirubin is estimated by van den Bergh reaction, where diazotised sulfanilic acid (sulfanilic acid in HCl and sodium nitrite) reacts with bilirubin to form a purple-colored complex, azobilirubin. Normal serum does not give a positive van den Bergh reaction.

iii. When bilirubin is conjugated, the purple color is produced immediately on mixing with the reagent, the response is said to be van den Bergh direct positive.

iv. When the bilirubin is unconjugated, the color is obtained only when alcohol is added, and this response is known as indirect positive.

v. If both conjugated and unconjugated bilirubins are present in increased amounts, a purple color is produced immediately and the color is intensified on adding alcohol. Then the reaction is called biphasic.

vi. In hemolytic jaundice, unconjugated bilirubin is increased. Hence van den Bergh test is indirect positive. In obstructive jaundice, conjugated bilirubin is elevated, and van den Bergh test is direct positive. In hepatocellular jaundice, a biphasic reaction is observed, because both conjugated and unconjugated bilirubins are increased (see Chapter 21).

2. Urinary Bilirubin

i. In all cases of jaundice, urine should be examined for the presence of bile pigments (bilirubin), bile salts and urobilinogen.

ii. Only conjugated bilirubin is soluble in water and is excreted in urine. Hence in prehepatic jaundice, when the unconjugated bilirubin is increased in blood, it does not appear in urine; hence called acholuric jaundice.

iii. But in obstructive jaundice, conjugation of bilirubin is taking place, which cannot be excreted through the normal passage, and so it is regurgitated back into bloodstream; this is then excreted through urine. So in obstructive jaundice, urine contains bilirubin; hence in old literature, it is called choluric jaundice.

3. Urinary Urobilinogen

i. In cases of obstruction, bile is not reaching the intestine and so urobilinogen may be decreased or absent in urine.

ii. In hepatocellular jaundice, urobilinogen is initially elevated, then decreases or disappears when the obstructive stage sets in and reappears when obstruction is cleared.

iii. Urobilinogen is absent in urine, when there is obstruction to bile flow. The first indication of the recovery is the reappearance of urobilinogen in urine.

iv. In hemolytic anemias, urobilinogen is increased.

v. Bilirubin is detected by Fouchet’s test and urobilinogen by Ehrlich’s test. The findings in urine in different types of jaundice are shown in Table 26.2. Table 26.3 shows the classification and causes for jaundice. Table 26.4 gives the tests to distinguish different types of jaundice. Bilirubin synthesis, excretion and jaundice are described in detail in Chapter 21.

4. Urine Bile Salts

Normally bile salts (sodium salts of taurocholic acid and glycocholic acid) are present in the bile; but are not seen in urine. Bile salts in urine are detected by Hay’s test. Positive Hay’s test indicates the obstruction in the biliary passages.

causing regurgitation of bile salts into the systemic circulation leading to its excretion in urine. Obstruction can occur in obstructive jaundice and also in hepatic jaundice due to obstruction of microbiliary channels caused by inflammation.

5. Aminopyrine Excretion Test

Aminopyrine is metabolized by the liver by N-demethylation to give CO₂. When ¹⁴C-labeled aminopyrine is given, the evolution of CO₂ corresponds to functioning liver cell mass. After an overnight fast, 2 µCi of amino (¹⁴C) pyrine and 2 mg unlabelled amino pyrine are administered orally. The breath is allowed to pass through calcium sulfate for drying and then bubbled through a solution of 2 ml ethanol and 1 ml (1M) hyamine hydroxide containing 2 drops of phenolphthalein. The change in color of the indicator indicates absorption of CO₂. Then the activity of ¹⁴CO₂ is measured in a scintillation counter. The ¹⁴CO₂ excretion during the test period is reduced in liver diseases affecting parenchymal cells like cirrhosis, acute and chronic hepatitis and neoplasia.

Causes of Jaundice

i. Causes of jaundice are enumerated in Boxes 26.4 and 26.5. The most common cause for hepatocellular jaundice is infection with hepatitis viruses (viral hepatitis). It may be due to hepatitis A virus (HAV), which is transmitted by the intake of contaminated food and water. Type A disease is usually self-limiting.

ii. Infection by hepatitis B virus (HBV) is transmitted mainly through parenteral contamination by infected blood or blood products. The virus is highly contagious and can be destroyed only by boiling for 20 minutes. It is a DNA virus, which destroys the hepatic cells. The surface antigen (HBs) (also called Australia antigen, because it was first demonstrated in an Australian aborigine settled in USA) is seen in the circulation of patients. For his contributions in the hepatitis prevention, Baruch Blumberg was awarded Nobel prize in 1976.

About 5% of world populations are carriers of HBV. In most cases of hepatitis B infection, complete recovery is possible, but about 1% cases progress to cirrhosis and eventual

</table>
hepatic failure. In another 2-5% cases, the disease goes to a chronic carrier state. About 1% cases go for chronic cirrhosis and eventual hepatic failure. In fact, the most common cause for cirrhosis in developing countries is the hepatitis B virus.

In a small fraction of such cases, development of hepatocellular carcinoma is also noticed. Thus HBV is an oncogenic virus. Medical personnel, including medical students, doctors, nurses and technicians are advised to take the hepatitis B vaccination.

iii. Hepatitis viruses type A, B, C, D, E and G are identified. While A and E are transmitted by oral route; B, C, D and G are transmitted through parenteral route. Box 26.6 gives the serology to define the type of viral hepatitis. Serological markers of hepatitis B infection are shown in Box 26.7.

II. Tests based on Synthetic Function of Liver

1. Serum albumin level

Almost all the plasma proteins except immunoglobulins are synthesised by the liver. Serum albumin (see Chapter 28) is quantitatively the most important protein synthesized by the liver, and reflects the extent of functioning liver cell mass.

Since albumin has a fairly long half-life of 20 days, in all chronic diseases of the liver, the albumin level is decreased. A reversal in A/G ratio is often the rule in cirrhosis, due to hypoalbuminemia and associated hypergammaglobulinemia (see Chapter 28).

Normal albumin level in blood is 3.5 to 5 g/dl; and globulin level is 2.5 to 3.5 g/dl.

The turn-over rates of haptoglobin and transferrin are lesser than albumin; hence they are useful to identify the recent changes in liver functions.

2. Serum globulins

They constitute immunoglobulins produced by B lymphocytes as well as alpha and beta globulins synthesized mainly by hepatocytes. Gamma globulins in the serum are increased in chronic liver diseases (chronic active hepatitis, cirrhosis). In cirrhosis, antibodies against intestinal bacteria are seen, since

Hepatitis D (delta) HBsAg and anti-HDV
Hepatitis E Anti-HEV
the cirrhotic liver cannot clear the bacteria reaching through circulation. Reference limits of serum immunoglobulins are shown in Appendix II. IgG is increased in autoimmune hepatitis. IgM is increased in primary biliary cirrhosis. IgA is increased in alcoholic liver disease. Further details of immunoglobulins are given in Chapter 49.

3. Prothrombin time (PT)
Since prothrombin is synthesized by the liver, it is a useful indicator of liver function. The half-life of prothrombin is 6 hours only; therefore, PT indicates the present function of the liver. PT is prolonged only when liver loses more than 80% of its reserve capacity. Vitamin K deficiency is also a cause for prolonged prothrombin time. In case of liver disease, the PT remains prolonged even after parental administration of vitamin K.

4. Alpha-fetoprotein (AFP)
It is a normal component of fetal blood. It disappears after birth within a few weeks. It is a tumor marker. Mild elevation is suggestive of chronic hepatitis or cirrhosis; drastic increase is seen in hepatocellular carcinoma, germ cell tumors and teratoma of ovary. Elevated AFP in the maternal serum is seen in cases of fetal open neural tube defects and also in cases with multiple fetuses or fetal death. Low AFP is seen in maternal serum in cases of fetal Down syndrome. Immuno assay is employed to test AFP. Reference limits are, up to 1 year < 30 ng/ml and adults (males and nonpregnant females) < 15 ng/ml.

5. Ceruloplasmin (Cp)
It is mainly synthesized by the hepatic parenchymal cells and a small part by lymphocytes. Level of Cp is increased in active hepatitis, biliary cirrhosis, hemochromatosis and obstructive biliary disease. The level is decreased in Wilson’s hepatolenticular degeneration (see Chapter 28).

6. Transthyretin (Prealbumin)
It is produced by the liver. It has a half-life of 2 days only. Hence it is a useful parameter to assess the hepatic function early in the course of liver disorders. Major function of this protein is to transport thyroxine and tri-iodothyronine.

7. Alpha-1 antitrypsin (AAT)
It is an acute phase reactant and is synthesized and secreted by the liver. AAT inactivates serine proteases (elastase and collagenase). Please see Chapter 28. It has got multiple alleles. PiZZ allele is characterized by deficient activity of this enzyme and individuals possessing such allele are prone for developing liver cirrhosis. Low levels are associated with neonatal cholestasis, progressive juvenile cirrhosis in children and micronodular cirrhosis in adults. Low levels are also seen in panlobular emphysema. It is increased in acute trauma, infections or after estrogen therapy and in many malignancies. Reference limits are shown in Appendix II.

8. Haptoglobin
It is synthesized in the liver. It transports free hemoglobin in the plasma to reticulo endothelial system. The free Hb (not bound to the haptoglobin) is freely filtered at the glomerulus and get precipitated in the tubules leading to damage to the kidney. Haptoglobin-bound Hb complex being large cannot be filtered at the glomerulus and thus retained in the circulation. Haptoglobin-bound Hb complex is degraded by the reticuloendothelial system leading to rapid depletion of haptoglobin from circulation in cases of exaggerated hemolysis. Low levels are seen with severe hepatocellular liver disease (deficient synthesis) and in hemolytic disease (increased rate of degradation). Being an acute phase reactant, its levels are high in inflammatory processes, trauma, infections, and myocardial infarction. Reference limits are shown in Appendix II. The turn-over rates of haptoglobin and transferrin are lesser than albumin; hence they are useful to identify the recent changes in liver functions.

9. Serum electrophoresis
Abnormal electrophoretic patterns are shown in Figure 28.1. Prealbumin is reduced in acute hepatitis. Albumin is decreased in cirrhosis. Alpha-1 globulins include glycoproteins and hormone-binding globulins. This band is decreased in hepatocellular disease almost parallel to albumin. It is increased in febrile illnesses and malignancies. Alpha-2 globulins and beta globulins, when increased suggest biliary obstruction. This pattern will help to differentiate biliary cirrhosis from nonbiliary cirrhosis. Gamma-globulins are increased in cirrhosis. The rise in gamma globulin will have wide base, suggestive of polyclonal gammopathy. Moreover, the dip between beta and gamma globulin tends to be bridged.

III. Tests based on Serum Enzymes (Liver Enzyme Panel)
The enzymes used in the assessment of hepatobiliary disease may be divided into two groups: (a) Those indicating hepatocellular damage and (b) those indicating cholestasis (obstruction).

1. Enzymes indicating hepatocellular damage
   i. Liver enzyme panel is described in detail in Chapter 23. Normal serum ALT (alanine amino transferase) is 10-35 IU/L.
   ii. The levels of amino transferases (ALT and AST) in serum are elevated in all liver diseases (Box 26.8).
   iii. Very high levels (more than 1000 units) are seen in acute hepatitis (viral and toxic).
   iv. The degree of elevation may reflect the extent of hepatocellular necrosis. In most cases the lowering of the level of transaminases indicates recovery, but a sudden fall from a very high level may indicate poor prognosis.
   v. Elevation of ALT is more in cases of hepatic disease compared to AST. But AST may be
more than ALT in **alcoholic liver disease**. In alcoholic liver disease, the actual values show only mild elevation; but a ratio of AST/ALT more than 2 is quite suggestive.

**vi. Moderate elevation** of amino transferases often between 100-300 U/L is seen in **alcoholic** hepatitis, autoimmune hepatitis, Wilson’s disease and nonalcoholic chronic hepatitis (Box 26.9).

**vii. Minor elevation** less than 100U/L is seen in chronic viral hepatitis (hepatitis C), fatty liver and in nonalcoholic steatohepatitis (NASH). In chronic hepatitis and cirrhosis of liver, serum ALT poorly correlates with the degree of liver cell damage.

**viii. A normal value need not rule out minor liver diseases.** On the other hand, normal persons may have elevated ALT levels. This is seen especially in obese persons. 1% loss of weight will reduce ALT values by 8%.

**IV. Markers of Obstructive Liver Disease**

1. **Alkaline Phosphatase (ALP)**
   
   **i.** Very high levels of alkaline phosphatase (ALP) are noticed in patients with cholestasis or hepatic carcinoma. The bile duct obstruction induces the synthesis of the enzyme by biliary tract epithelial cells (see Chapter 23).

2. **Gamma Glutamyl Transferase (GGT)**
   
   GGT is clinically important because of its sensitivity to detect **alcohol abuse**. GGT level in alcoholic liver disease roughly parallels the alcohol intake (see Chapter 23). Elevated levels of GGT are observed in parenchymal diseases of the liver, mild elevation of ALP is noticed. But in hepatitis, inflammatory edema produces an obstructive phase, during which ALP level is elevated (Table 26.4).

   **iii.** Very high levels of ALP (10-12 times of upper limit) may be noticed in extrahepatic obstruction (obstructive jaundice) caused by gallstones or by pressure on bile duct by carcinoma of head of pancreas. Intrahepatic cholestasis may be due to virus (infective hepatitis) or by drugs (chlorpromazine). ALP is produced by epithelial cells of biliary canaliculi and obstruction of bile with consequent irritation of epithelial cells leads to secretion of ALP into serum.

   **iv.** Drastically high levels of ALP (10-25 times of upper limit) are seen in **bone diseases** where osteoblastic activity is enhanced. For example, Paget’s disease (osteitis deformans), rickets, osteomalacia, osteoblastoma, metastatic carcinoma of bone and hyperparathyroidism.

   **v.** There are 6 iso-enzymes for ALP. The one, which is inhibited by phenylalanine is of placental origin. It is found in blood in normal pregnancy. An iso-enzyme closely resembling the placental form is characteristically seen in circulation in about 15% cases of carcinoma of lung, liver and gut and named as **Regan iso-enzyme** or carcinoplacental iso-enzyme (see Chapter 23).
in chronic alcoholism, pancreatic disease, myocardial infarction, renal failure, chronic obstructive pulmonary disease and in diabetes mellitus. In liver diseases, GGT elevation parallels that of ALP and is very sensitive of biliary tract disease.

3. Nucleotidase
It is also called nucleotide phosphatase (NTP). The level is increased in hepatobiliary disease and closely parallels the ALP levels (see Chapter 23). S'-nucleotidase elevation is not noticed in childhood and pregnancy as in the case of ALP. Hence estimation is more specific for obstructive liver disease.

4. Special tests
In special circumstances, special tests may be done to confirm the diagnosis. Some examples are: Glutathione-S-transferase activity is a very sensitive indicator of liver function. Alpha fetoprotein (AFP) is a tumor marker. It is described above, under globulins.

V. Tests on the Metabolic Capacity of Liver
1. Blood ammonia
It is an index of urea synthesis by liver. It is a useful test in hepatic encephalopathy; but it has low diagnostic significance. The major source of ammonia in the blood is bacteria of gastrointestinal tract. It is produced by action of intestinal bacterial protease, urease and amino acid oxidase on the intestinal contents. The ammonia is later converted to urea by the liver, but this activity is considerably decreased in hepatic cell damage; or by the development of portocaval shunts causing portal blood to bypass the liver.

The ammonia level is an indicator of the capacity of the liver to eliminate ammonia generated in intestine. Raised ammonia in the serum/plasma is suggestive of cirrhosis and/or development of collateral circulation. It may occur with portocaval anastamosis.

Arterial blood should be used for blood ammonia estimation. Estimation of ammonia may be helpful to exclude or diagnose hepatic failure in patients with unexplained stupor or coma.

In neonates suspected to have urea cycle disorders, ammonia estimation is indicated.

Precautions: Fasting plasma/serum is used for ammonia estimation. Stringent precautions are to be maintained. Vacutainers must be used and the blood withdrawn until it is full. Partial filling allows entry of air. Glutamine in the specimen is a source of ammonia contamination. This can be avoided by the placing the sample immediately in ice and centrifuging to separate plasma or serum and carry out the assay as soon as possible. EDTA or heparin can be used as anticoagulants. Enzymatic assay (with glutamate dehydrogenase) is done by photometry or by ammonia selective electrode. Reference limits of venous ammonia nitrogen are given in Appendix I.

2. Other rare tests
Substances which are selectively metabolised by the liver were used to assess liver function previously, e.g. Galactose tolerance test, Bromsulphthalein excretion test, etc. As these are seldom used nowadays in clinical practice, these tests are not described in this textbook.

3. Immunological tests in liver disease
IgG level is increased in chronic hepatitis, alcoholic and autoimmune hepatitis. It shows a slow and sustained increase in viral hepatitis. IgM shows marked increase in primary biliary cirrhosis and moderate increase in viral hepatitis and cirrhosis. IgA is increased in alcoholic cirrhosis and primary biliary cirrhosis.

Autoantibodies: Autoimmune chronic hepatitis is due to defective suppressor T cells leading to production of autoantibodies against hepatocyte surface antigens (see Table 26.5). Commonly encountered autoantibodies in hepatic autoimmune disorders are:

- Antinuclear antibodies
- Double-stranded DNA
- Smooth muscle (actin) antibody
- Asialoglycoprotein receptor autoantibody
- Anti-LKM1 antibody
- Anti-LKM1 muscle ab
- Anti-LKM1 smooth

VI. Selection of Tests
Liver function tests are the most common group of biochemical tests done to diagnose and monitor the course of liver disease. The increased incidence of infectious diseases like viral hepatitis and leprosporosis require these tests to be done in all patients with unexplained illness.

Several different tests are to be done for overall assessment of the liver function. Table 26.6 gives the different tests and the alterations in different types of liver diseases.

</table>

Most commonly employed liver function tests in clinical practice are serum bilirubin, albumin, ALP, ALT, AST and GGT. Cholesterol level in blood is also increased in obstructive jaundice due to defective excretion through bile. In general ALT and ALP distinguishes the pattern of liver disease. Albumin determines the chronicity and prothrombin time determines the severity of liver dysfunction.

**GASTRIC FUNCTION**

The gastric function is not meant for undergraduates, is not a "must know subject". This is mainly meant for advanced study.

**Mechanism of HCl Secretion**

i. The gastric mucosa has different types of cells: (a) the mucous secreting surface epithelial cells, (b) the oxyntic or parietal cells which secrete acid, and (c) the chief cells or peptic cells that secrete enzymes. The daily volume of gastric secretion is around 2000 ml. The HCl secreted by the parietal cells is of high concentration (0.15 M) with a pH as low as 0.8.

ii. The parietal cells transport protons against a concentration gradient at the extracellular fluid pH of 7.4. It is an energy-requiring process.

iii. The K+ activated ATPase is necessary for the production of HCl (Fig. 26.2). It is located on the luminal side of the plasma membrane.

iv. The H+ ions are generated within the cell by ionization of carbonic acid. The carbonic anhydrase is active in the parietal cells.

v. One molecule of ATP is hydrolyzed for every molecule of H+ secreted (Fig. 26.2). The hydrolysis of ATP is coupled with an exchange of K+ for H+. The hydrogen ions are then secreted into gastric lumen.

vi. Side by side with the H+ to K+ exchange, a bicarbonate to chloride exchange is also taking place. When the bicarbonate level within the cell increases (formed from H2CO3), it is reabsorbed into bloodstream, in exchange for Cl−. The chloride is then secreted into the lumen to form HCl.

vii. This would account for the alkaline tide of plasma and urine, following hydrochloric acid secretion, immediately after meals (Fig. 26.3).

**Regulation of Acid Secretion**

i. Gastrin, the gastrointestinal peptide hormone secreted by G cells, stimulates secretion of HCl. The secretion of gastrin is cut off by acidic pH by a feedback regulatory control (Fig. 26.3).

ii. The most potent stimulus for acid secretion is histamine, which acts through specific H2 receptors on the gastric mucosa.

**Other constituents of gastric secretions**

The major enzyme present in gastric juice is pepsin. Its action on dietary proteins is indicated in Chapter 14. One of the functions of HCl is to activate the zymogen pepsinogen to pepsin by partial proteolysis. In addition, the HCl helps in the absorption of iron and calcium. The gastric juice also contains a glycoprotein required for the absorption of B12, the Castle's intrinsic factor.
Assessment of Gastric Function

In fractional test meal or FTM, the fasting stomach contents are aspirated and the secretion is stimulated by giving test meals. Different samples are collected and the acidity (free and total) of each sample is measured. The FTM is not done nowadays; but the modified version, though rare, is still in use. It is described below.

Pentagastrin Stimulation Test

In the fasting condition, the gastric juice is aspirated through a Ryle’s tube (residual juice). The gastric juice secreted for the next one hour is collected as a single sample (basal secretion). The gastric secretion is now stimulated by giving pentagastrin. It is a synthetic peptide having the biologically active sequence of gastrin. (Pentagastrin has the following structure: Butyl oxycarbonyl - beta Ala - Trp - Met - Asp - Phe - NH₂). Pentagastrin is given in a dose of 6 mg/kg body weight. The gastric secretion is collected every fifteen minutes for the next 1 hour.

Basal acid output (BAO) is the acid output in millimol per hour, in the basal secretion (in the absence of all intentional and avoidable stimulation).

Maximal acid output (MAO) is the acid output in millimol per hour, given by the sum of the acid output of the four 15-minute samples after the stimulation.

Peak acid output (PAO) is the acid output in millimol per hour, given by the sum of the acid output of the 2 consecutive 15-minute samples having the highest acid content. The value is multiplied by 2 to get the value for one hour. Normal values are given in Table 26.7.

Interpretations of Gastric Juice Analysis

i. Zollinger Ellison syndrome. This condition results from a gastrin secreting tumor (gastrinoma of the pancreas). There is no feedback regulation of gastrin secretion. There is very high level of gastric acid output along with elevated serum gastrin levels. In this condition, BAO is >15 mmol/hour (may be as high as 150 mmol/hour) and BAO/PAO ratio is 0.6 or higher.

ii. In chronic duodenal ulcer, BAO, MAO and PAO are significantly elevated. BAO may vary from 4-6 mmol/hr and a BAO/PAO ratio of more than 0.3 indicates increased basal secretory drive. Causes for hyperacidity and hypoacidity are shown in Box 26.10.

Estimation of Free Acidity and Total Acidity

The fasting stomach contents are first withdrawn, then the patient is given a test meal (porridge, rice gruel, black coffee or toast, etc.). Gastric juice is withdrawn at 1/2 an hour intervals for next 2 hours. The free and total acid content of each sample

Box 26.10. Causes for Hyper- and Hypoacidity

Hyperacidity is seen in:
1. Duodenal ulcer
2. Gastric cell hyperplasia
3. Carcinoid tumors
4. Zollinger-Ellison syndrome
5. MEN (multiple endocrine neoplasia)
6. Excessive histamine production as in systemic mastocytosis and basophilic leukemia.

Hypoacidity is seen in:
1. Gastritis
2. Gastric carcinoma
3. Partial gastrectomy
4. Pernicious anemia
5. Chronic iron deficiency anemia.

is measured by titration with N/10 NaOH. The free acidity measures only the HCl, when Topfer's reagent is used as indicator (pK = 3.5). The total acidity includes HCl and other organic acids and tested by phenolphthalein as indicator (pK = 10.5).

Augmented Histamine Test
Histamine, the most potent stimulus of gastric secretion is given and the response in acid secretion is noted. The augmented histamine test (AHT) is done by giving 0.04 mg/kg of histamine subcutaneously, followed by collection of gastric contents. If the hypoacidity does not respond to histamine, it is said to be true hypoacidity or histamine fast achlorhydria.

This is characteristic of pernicious anemia. But in other cases of hypoacidity, gastric acid secretion occurs in response to histamine (false hypoacidity).

Histamine may produce hypotension. As a precaution, an initial dose of antihistamine may be given to block the H1 receptor effects of histamine. Cimetidine blocks H2 histamine receptors of stomach and helps in healing of peptic ulcers.

Tubeless gastric analysis: This avoids the discomfort of passing a stomach tube. It is used only as a screening test. Fasting secretion is stimulated by giving a histaglate. After one hour, a dye bound resin (Azure-A) is given orally. In the presence of HCl, the resin releases the dye. This release is proportional to the surrounding pH. The released dye is absorbed and later excreted through urine. The quantity of dye in urine provides an indication to the presence or absence of HCl.

Other relevant clinical laboratory tests
a. Serum gastrin level may be estimated by radioimmunoassay. In normal cases, the level is usually <10 picomol/L (<200 nanogram/L) and never above 50 pmol/L. In Zollinger Ellison syndrome, the values may be more than 100 pmol/L.
b. Occult blood in gastric juice indicates gastric carcinoma, gastric ulcer or duodenal ulcer.
c. The presence of bile and undigested food indicates the stagnation of food or regurgitation of bile.

d. Gastric ulcers are perpetuated by the infection of Helicobacter pylori. Marshall and Warren were awarded Nobel Prize in 2005 for their discovery of the bacterium *H. pylori* and its role in acid peptic disease. The bacteria produce ammonia, with the help of bacterial urease. So, the organism can escape the attack of acidic gastric juice. *H. pylori* infection is identified by the presence of urease enzyme in gastric biopsies.

### PANCREATIC FUNCTION TESTS

The pancreatic function is not meant for undergraduates, is not a "must know subject". This is mainly meant for advanced study.

The exocrine pancreas secretes about 1000-2500 ml of juice in 24 hours. The fluid is alkaline and contains bicarbonate and enzymes. This secretion is under the control of the hormones, Secretin and cholecystokinin. Secretin is produced under the stimulation of gastric HCl. Secretin produces a secretion with high bicarbonate content. Gastrin stimulates production of cholecystokinin (CCK), which in turn produces pancreatic secretion rich in enzymes. The major enzymes present in pancreatic juice are amylase, lipase and proteolytic enzymes (trypsin, chymotrypsin, carboxypeptidase, elastase) as their zymogens (see Chapter 14).

**Assessment of Pancreatic Function**

**Measurement of pancreatic enzymes:** Amylase or alpha-1,4-glucosidase is the major enzyme which digests starch (see Chapter 23). The serum amylase contains the P (pancreatic) and S (salivary) isoenzymes. These two can be distinguished by the inhibition test. A protein inhibitor, present in alcoholic extracts of wheat will selectively inhibit the S isoenzyme. Normal amylase level in serum is 50-120 units. The level rises within 5 hr of the onset of acute pancreatitis and the level reaches a peak within 12 hours. But the level need not be parallel to the severity of the disease. Within 2-4 days of the attack, the level returns to normal. As the serum amylase level starts falling, urinary amylase level rises. If the sample is collected too early, the serum amylase levels may not show the expected rise. If the sample is collected too late, again serum amylase may be low due to necrosis of the pancreatic tissue. Calculation of clearance ratio will avoid these defects.

\[
CR = \frac{U_{\text{amylase level}} \times \text{Scr}}{S_{\text{amylase level}} \times \text{Ucr}} \times 100
\]

CR is clearance ratio, Scr is serum creatinine level and Ucr is urinary creatinine level. In patients with acute pancreatitis, the ratio varies from 7-15%. The normal ratio is 1-4.4%

Amylase level in blood is mildly increased in cases of cholecystitis, peptic ulcer, diseases of mesentery and obstruction of intestine. A small percentage of patients with acute pancreatitis fails to show any rise. No significant change or only mild elevation is noticed in chronic pancreatitis.

</tbody>
</table>

**Macroamylasemia** is a condition characterized by persistent elevation of serum amylase activity with no apparent clinical symptoms of pancreatic disease. The amylase complexes with immunoglobulins, which prevents renal excretion. Macroamylasemia by itself is not a disease, but it may be an early marker of pancreatic disease.

**Serum lipase** is the major lipolytic enzyme which hydrolyzes glycerol esters of long chain fatty acids. The level in blood is highly elevated in **acute pancreatitis** and this persists for 7-14 days. Thus lipase remains elevated longer than amylase. Moreover, lipase is not increased in salivary diseases. Therefore, lipase estimation has advantage over amylase.

**Other pancreatic enzymes:** A simple screening test for trypic activity of feces may be done using serial dilutions of stool extract. Drops of serially diluted extract are placed on a piece of X-ray film along with a control sample. After an hour at 37°C, the extract is washed off, and the film examined for trypic activity by noting translucency of the film.

**Secretin-cholecystokinin test:** In the fasting condition, the duodenal contents are first aspirated. Then secretin 1 unit/kg body wt is given followed by CCK. Again the duodenal contents are aspirated for 80 min at 10 min intervals. Each sample is analyzed for volume, bicarbonate content and amylase activity. If the bicarbonate secretion is more than 15 mmol/L at 30 min, the secretory capacity is normal. Table 26.8 gives the normal response and abnormal pattern in diseases.

**Lundh test:** The test meal is composed of milk powder, vegetable oil and glucose to make 6% fat, 5% protein and 15% carbohydrate. After aspirating the duodenal contents, 500 ml of fluid meal is given. Then duodenal secretions are collected at 30 min intervals for 2 hrs. The trypic activity of duodenal aspirates are measured. Benzoyl arginine ethyl ester (BAEE) is incubated with the aspirate. The benzoic acid liberated after trypic hydrolysis of the substrate is calculated. In chronic pancreatitis, the trypic activity is decreased, but not in carcinoma of pancreas.

**Indirect tests** of pancreatic function include: (a) Measurement of tumor markers like carcinoembryonic antigen (CEA), alpha fetoprotein (AFP), and pancreatic oncofetal antigen, (b) Fat balance studies, (c) Measurement of leucine amino peptidase which is usually elevated in pancreatic carcinoma.

**Estimation of sweat electrolytes:** In pancreatic fibrocystic disease, sodium and chloride are increased in sweat. The disease is characterized by thick viscous secretion of exocrine glands, including pancreas, salivary, tracheal, bronchial and sweat glands. Pilocarpine is given into the skin to stimulate the secretion of sweat glands. The sweat is absorbed into a filter paper, which is weighed before and after the absorption. The difference in weight of the filter paper gives the weight of the sweat. From the specific gravity and weight, the volume is determined. Then sodium and chloride are eluted from the filter paper and separately determined. Sweat chloride levels of more than 60 mmol/L, on two separate occasions, is diagnostic of cystic fibrosis.

**STUDIES ON MALABSORPTION**

Malabsorption may result from defective digestion or faulty absorption or from both. Reduction of absorptive surface may result from i) celiac disease; ii) gluten sensitive enteropathy; iii) tropical sprue; iv) ideopathic steatorrhea; v) extensive surgical removal of ileum; vi) Crohn's disease or vii) Wipple's disease. Pancreatic disease can lead to defective digestion. The following tests are useful to assess the malabsorption states.

**Fat balance studies:** The estimation of the fat in stool is done. When feces contains split fatty acids, it points to a normal pancreatic function, but defective absorption. On the other hand, if the fat excreted is neutral fat, it is due to defective digestion, and is more in favor of pancreatic disease.

**D-Xylose absorption test:** Xylose is absorbed easily, but not rapidly metabolized. Hence its blood level is an index of the rate of absorption. An oral dose (25 g) of xylose is given to the fasting patient. In normal subjects, more than 23% of the administered dose should be excreted during the five hours, out of which 50% excretion should occur within the first 2 hours. In severe malabsorption, the total excretion is low. In mild malabsorption, it may only be delayed.

**Starch tolerance test:** A usual GTT is done on the first day (see Chapter 24). On the following day, 100 g soluble starch is given and the rise in glucose level is noted. In normal cases, the peak level in the starch test will be at least 80% of the peak level of usual GTT.

**Schilling test:** It is done to note the malabsorption of vitamin B₁₂. One microgram of radiolabelled (⁶⁰Co) vitamin B₁₂ is given orally. Then a flushing dose of non-radiolabelled B₁₂ is given parenterally to saturate-free binding sites and ensure excretion of the labelled B₁₂. If absorption is defective, radioactivity in urine is minimal, which may be enhanced by simultaneous oral administration of intrinsic factor (see Chapter 34, under vitamin B₁₂).
CHAPTER 27

Kidney Function Tests

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Glomerular functions
2. Tubular functions
3. Abnormal constituents of urine
4. Clearance tests: Inulin, Creatinine and Urea
5. Proteinuria
6. Tests for tubular functions

The major functions of the kidneys are to excrete metabolic waste products as well as to maintain water, pH, electrolyte balance, production of calcitriol and hemopoietin (Box.27.1). A decrease in kidney function is due to a reduction in the performance of nephrons. The functional unit of the kidney is the **nephron**, which is composed of the Bowman's capsule with the glomerular tuft of capillaries, the proximal convoluted tubule (PCT), loop of Henle, distal convoluted tubule (DCT) and collecting tubules.

RENAL FUNCTION TESTS
The classification of renal functional tests is shown in Box 27.2.

Glomerular Function
When the blood is perfused through the Bowman's capsule, an ultrafiltrate of the blood is produced in glomerulus, while the cells and proteins are retained in the blood. The sieves of the glomeruli are such that hemoglobin (mol. wt. 67,000 D) is passed through to be excreted in urine, while albumin (mol. wt. 69,000 D) is retained in the blood. Therefore, the earliest manifestation of the abnormal function of the glomeruli is the appearance of albumin in urine.

Glomerular Filtration Rate (GFR)
1. GFR is decreased when BP is below 80 mm of mercury. The GFR is reduced when there is obstruction to the renal flow (calcui, enlarged prostate, etc.). It also decreases with age.
2. The renal blood flow is about 700 ml of plasma or 1200 ml of blood per minute.

Some of the tests mentioned above are done only for detailed study of renal function and not in routine clinical practice. However, they are also described (in small font) considering the high incidence of chronic kidney disease as a complication of widely prevalent diseases like diabetes mellitus, hypertension and misuse of pain killer drugs. The undergraduate students should have a clear idea about the routinely done investigations only.

iii. The glomerular filtration rate (GFR) is 120-125 ml per minute in a person with 70 kg body weight.

iv. Glomerular filtrate formed is about 170 to 180 liters per day, out of which only 1.5 liters are excreted as urine. This means that most of the water content of glomerular filtrate is reabsorbed.

Functions of the Tubules

i. When the glomerular filtrate is formed, it contains almost all the crystalloids of plasma. In the proximal convoluted tubules, about 70% water, Na⁺ and Cl⁻ as well as 100% glucose, amino acids and K⁺ are reabsorbed.

ii. Urea, phosphate and calcium are partially absorbed (Table 27.1).

iii. The major processes occurring in renal tubules are the reabsorption or secretion of solutes and reabsorption of water. Table 27.3 shows the functions of different parts of the renal tubules.

Renal Threshold and Tubular Maximum

i. Compounds whose excretion in urine is dependent on blood level are known as threshold substances. At normal or low plasma levels, they are completely reabsorbed and are not excreted in urine. But when the blood level is elevated, the tubular reabsorptive capacity is saturated, so that the excess will be excreted in urine (Table 27.2).

ii. The renal threshold of a substance is the plasma level above which the compound is excreted in urine.

### Table 27.2. Threshold value of some common substances excreted through urine

</tr>
<tr>
<td>4. Calcium</td>
<td>10 mg/dl</td>
</tr>
</tbody>
</table>

iii. The maximum reabsorptive capacity of the substances is known as the tubular maximum or Tm.

iv. For glucose, the renal threshold is 180 mg/dl and Tm is 375 mg/min. In other words, glucose starts to appear in urine when blood level is more than 180 mg/dl, and all the glucose molecules above 375 mg are excreted in the urine. Table 27.2 gives a list of threshold substances.

v. In abnormal conditions, the renal threshold may be lowered so that even at lower blood levels, compounds are excreted in urine, e.g. renal glycosuria (glucose); and renal tubular acidosis (bicarbonate).

Reabsorption of Solute in Tubules

1. Sodium

   i. In the proximal convoluted tubules, the reabsorption of sodium is by co-transport mechanism, accompanied by glucose, amino acids. These mechanisms are coupled with the activity of sodium-potassium-ATPase. There is passive transport of equivalent amounts of chloride to maintain the electrical neutrality. The net effect is the reabsorption of sodium chloride along with glucose, amino acids, etc.

   ii. The co-transport of glucose is inhibited by ouabain and phlorhizin. The sodium-Pi co-transport system is inhibited by parathyroid hormone and facilitated by calcitriol.

   iii. In addition, Na⁺ to H⁺ exchange system also exists in the PCT. This is an antiport system, where sodium ions
are reabsorbed, in exchange for hydrogen ions. This also achieves a net reabsorption of bicarbonate (Chapter 29). When hydrogen ions are to be conserved, sodium to potassium exchange occurs.

2. Calcium
90% of calcium is reabsorbed from the glomerular filtrate. However, the regulation of calcium balance is achieved at the distal convoluted tubules. The major factors regulating calcium reabsorption are parathyroid hormone and vitamin D (Chapter 35).

3. Uric acid
It is almost completely reabsorbed in the proximal convoluted tubules, by both active and passive carrier mediated processes. The drug, probenecid is secreted by the tubule, and competes with the uric acid for reabsorption. Since probenecid increases uric acid excretion, it is uricosuric. There is also active secretion of uric acid into the tubules. 85% of the excreted uric acid is derived by tubular secretion.

4. Urea
Urea is freely filtered by the glomerulus, but about 40% is reabsorbed actively by the tubules. Rate of reabsorption of urea varies inversely with tubular flow and accounts for elevation of blood urea when renal function is low. The concentration of urea in urine is about 70 times that of plasma. Urea forms 80% of total urinary solutes. Urine is roughly a 2% solution of urea.

5. Creatinine
Creatinine is neither reabsorbed nor secreted. The urinary concentration is about 70% that of plasma.

6. Potassium
About 70% of potassium in the glomerular filtrate is reabsorbed by proximal convoluted tubules. Net secretion of K⁺ occurs at the distal tubules, in exchange for Na⁺ reabsorption, under the effect of aldosterone. However, when the H⁺ concentration is increased, H⁺ ions are exchanged for K⁺. Table 27.4 gives the urinary excretion of solutes under normal conditions.

Reabsorption of Water
i. The osmolality of urine can vary between 60-1200 milliosmol/kg (specific gravity = 1.003 to 1.032), depending on the water intake and state of hydration.

ii. The GFR is about 125 ml/minute. In the proximal convoluted tubules, most of this is reabsorbed. Since Na⁺, Cl⁻ and HCO₃⁻ ions are absorbed, water has to move along with the solutes to maintain the osmolality. Hence, this is called obligatory reabsorption of water.

iii. By the time it reaches the Loop of Henle, the filtrate is only 25 ml/min. Here sodium is again reabsorbed, but water absorption is less so that, urine is hypotonic at this level.

iv. By the time urine reaches distal tubules, the flow rate is reduced to 16 ml/min. Here again water is reabsorbed, but it is under the influence of ADH. Therefore, this is called facultative reabsorption of water.

Box 27.3. Clinical Applications of Diuretics

1. Osmotic diuretics act by interfering with reabsorption of solute so that more water is obligatorily excreted along with the solute. Osmotic diuretics mainly act at the proximal convoluted tubules, e.g. mannitol.

2. When carbonic anhydrase is inhibited, the dissociation of H₂CO₃ to H₂O and CO₂ is not taking place. Net effect is decreased reabsorption of bicarbonate, sodium and water. Thus acetazolamide, a carbonic anhydrase inhibitor, will cause diuresis.

3. The thiazide group of diuretics act on distal convoluted tubules, inhibiting sodium reabsorption and therefore more water is excreted obligatorily.

4. Frusemide acts on the ascending limb of loop of Henle, inhibiting chloride reabsorption along with Na⁺ and water. So, chances of K⁺ depletion are present.

5. Aldosterone antagonists (Spironolactone) and potassium sparing diuretics (amiloride and triamterene) are also used as diuretics both inhibiting sodium reabsorption.

6. In congestive cardiac failure, diuretics form an important part of therapeutics. When the heart is not working properly, water from extravascular space is not returning to vascular compartment causing edema (Chapter 28, under albumin). This extra water may be removed by judicious use of diuretics.
v. ADH secretion, in turn, is controlled by hypothalamic osmoreceptors. The osmolality of plasma is the stimulus for modulating ADH secretion.

vi. Thus, when urine reaches the collecting ducts, the flow rate is only about 1 ml/min, and the urine is hypertonic.

ABNORMAL CONSTITUENTS OF URINE
In clinical biochemistry, urine is tested and report is given on a urine sample. The procedure is called urine analysis or urinalysis. For details of the tests, the student may refer the practical textbook. The routine analysis of urine is the most popular test in hospital practice. The following parameters are usually checked when reporting on a urine sample.

A. Physical Characteristics of Urine
i. Volume: The average output of urine is about 1.5 liters per day. Urine volume may be increased in excess water intake, diuretic therapy, diabetes mellitus and in chronic renal diseases. Urine volume may be decreased in excess sweating, dehydration, edema of any etiology, kidney damage.

ii. Appearance: See Table 27.5.

iii. Odor: Normal urine has a faintly aromatic smell due to presence of volatile organic acids. Urine in diabetic Keto acidosis may have fruity odor due to acetone.

iv. Color: Normal urine is straw-colored (amber-yellow) due to the pigment, urochrome. Presence of bilirubin makes urine yellow in jaundiced patients.

v. Specific gravity: Normal specific gravity of urine is 1.015-1.025. Theoretical extremes are 1.003 to 1.032. The specific gravity will be decreased in excessive water intake, in chronic nephritis, and in diabetes insipidus. It is increased in diabetes mellitus, in nephrosis and in excessive perspiration.
In chronic renal failure, the specific gravity of urine is fixed at 1.010. The earliest manifestation of renal damage may be the inability to produce concentrated urine. A summary of the findings is listed in Table 27.6.

In chronic renal failure, the specific gravity of urine is fixed at 1.010. The earliest manifestation of renal damage may be the inability to produce concentrated urine. A summary of the findings is listed in Table 27.6. The reasons for false positive and false negative tests are shown in Table 27.7.

B. Chemical Characteristics of Urine

1. Reaction to Litmus

The pH of urine varies from 5.5 to 7.5. If diet is rich in proteins, sulfuric and phosphoric acids are produced from amino acids, and the urine becomes acidic. If the diet is rich in vegetables, urine is alkaline because the organic acids (citric and tartaric) present in vegetables are converted to bicarbonate in the body.

2. Proteins

   i. Proteinuria is an important index of renal diseases. In normal urine, protein concentration is very low, which cannot be detected by the usual tests. These proteins are secreted by the tubular epithelial cells.

   ii. The proteinuria is commonly assessed by the **heat and acetic acid test**. Now dipstick test is replacing the old methods. Micro-albuminuria (see last part of this chapter) is detected by radial immunodiffusion or immunoturbidometry methods.

   iii. Measurement of urinary proteins may be carried out to:

      a. Establish the renal disease
      b. Define the nature of renal disease
      c. Define the degree of renal dysfunction, and
      d. Monitor the response to treatment.

Proteinuria is described in detail under Markers of glomerular permeability.

3. Blood

Hematuria is seen in nephritis and postrenal hemorrhage. Hemoglobinuria is due to abnormal amount of hemolysis. Occultest tablets and Hemastix strips are available for rapid testing of blood in urine.

4. Reducing Sugars (Glycosuria)

Benedict’s test is described in Chapter 6. The test may be used as a semiquantitative method for sugar estimation in urine. The approximate concentration of sugar will be 0.5 g/100 ml (green), 1 g% (yellow), 1.5 g% (orange) and 2 g% (red). Many substances may occur in urine which will cause reduction of Benedict’s reagent. These are listed in Chapter 24. Dipstick is now replacing the old Benedict’s test for detection of glucose in urine.

5. Ketone Bodies

They are acetoacetic acid, beta hydroxybutyric acid and acetone. Ketonuria is seen in diabetes mellitus, starvation, persistent vomiting, von Gierke’s disease, etc. Ketone bodies are analyzed by **Rothera’s test**. Test is described in Chapter 11, under ketosis. Nowadays, ketostix strips are available for rapid test for ketone bodies.

6. Bile Salts

Bile salts are present in urine during the early phase of obstructive jaundice (Chapter 26). Their presence is identified by Hay’s test.
7. Bile Pigments
Bilirubin appears in the urine during obstructive jaundice (Chapters 21 and 26). It is detected by Fouchet’s test.

8. Urobilinogen
The oxidation of urobilinogen to urobilin is supposed to be the cause of the deepening of color of urine on standing. In hepatocellular jaundice, urobilinogen is absent in urine. The earliest sign of recovery is the re-appearance of urobilinogen in urine (Chapter 26). It is identified by Ehrlich test or Schlesinger’s test. Normal urine contains only traces of urobilinogen, so that the above two tests are only weakly positive. But, in hemolytic jaundice, where excretion of urobilinogen is increased, these tests will be frankly positive.

In addition to this routine analysis of urine, abnormal metabolites or metabolic intermediates may be tested in specific cases, e.g. amino acids, mucopolysaccharides. The estimation of 24-hour excretion of normal urinary constituent may also be done in specific cases, e.g. calcium in hyperparathyroidism, uric acid in hyperuricemia and phosphate in Fanconi’s syndrome.

Nonprotein Nitrogen (NPN)
These include urea, creatinine and uric acid. The major route of excretion of these compounds is urine. In kidney dysfunction, the levels of these compounds are elevated in plasma. Of the three, creatinine estimation is the most specific and sensitive index of renal function.

Other minor components of NPN are urobilinogen, indican, ammonia and amino acids.

Estimation of NPN along with electrolytes (sodium, potassium) and assessment of acid base balance are used as a panel of tests to indicate abnormalities in kidney function. Normal blood and urine levels of these parameters are shown in Table 27.8.

### MARKERS OF GFR

#### Clearance Tests
Measurement of the clearance is predominantly a test of glomerular filtration rate (GFR). See Figure 27.1. Measurement of glomerular filtration rate (GFR) provides the most useful general index for the assessment of the severity of renal damage. A decrease in the renal function is due to the loss of functional nephrons, rather than a decrease in the function of individual nephron. The relation between clearance value and GFR is shown in Table 27.9 and Figure 27.1.

GFR is the product of filtration rate in single nephrons and the number of nephrons in both kidneys. Substantial kidney damage occurs before GFR is decreased.

GFR is also affected by age, sex, body size, protein intake and pregnancy. Normal GFR for young adults is 120-130 ml/minute/1.73 m². GFR is constant in a normal individual, but may vary even with normal kidney function. A decline with age is significant and more than 25% of people older than 70 years may have a GFR less than 60 ml/minute. This may be due to decline with age or any systemic disease that may be coexisting.

GFR cannot be measured directly, it is estimated from the clearance of a filtration marker.

### Definition

i. Clearance is defined as the volume of blood or plasma completely cleared of a substance per unit time and is expressed as milliliter per minute.

ii. It is expressed as milliliter of plasma per minute (not as g or mg).

iii. Clearance estimates the amount of plasma that must have passed through the glomeruli per minute with complete removal of that

**Chapter 27: Kidney Function Tests**

Bilirubin appears in the urine during obstructive jaundice (Chapters 21 and 26). It is detected by Fouchet’s test.

In hepatocellular jaundice, urobilinogen is absent in urine. The earliest sign of recovery is the re-appearance of urobilinogen in urine (Chapter 26). It is identified by Ehrlich test or Schlesinger’s test. Normal urine contains only traces of urobilinogen, so that the above two tests are only weakly positive. But, in hemolytic jaundice, where excretion of urobilinogen is increased, these tests will be frankly positive.

In addition to this routine analysis of urine, abnormal metabolites or metabolic intermediates may be tested in specific cases, e.g. amino acids, mucopolysaccharides. The estimation of 24-hour excretion of normal urinary constituent may also be done in specific cases, e.g. calcium in hyperparathyroidism, uric acid in hyperuricemia and phosphate in Fanconi’s syndrome.

Nonprotein Nitrogen (NPN)
These include urea, creatinine and uric acid. The major route of excretion of these compounds is urine. In kidney dysfunction, the levels of these compounds are elevated in plasma. Of the three, creatinine estimation is the most specific and sensitive index of renal function.

Other minor components of NPN are urobilinogen, indican, ammonia and amino acids.

Estimation of NPN along with electrolytes (sodium, potassium) and assessment of acid base balance are used as a panel of tests to indicate abnormalities in kidney function. Normal blood and urine levels of these parameters are shown in Table 27.8.
substance to account for the substance actually appearing in the urine.

\[
\text{Clearance} = \frac{\text{mg of substance excreted per minute}}{\text{mg of substance per ml of plasma}}
\]

It is calculated by using the formula:

\[
C = \frac{U \times V}{P}
\]

where \( U \) = concentration of the substance in urine; \( P \) = concentration of the substance in plasma or serum and \( V \) = the ml of urine excreted per minute. The value is expressed as ml/minute.

If the substance is freely filtered across the capillary wall, and neither secreted nor reabsorbed, then its clearance is equal to glomerular filtration rate. A substance which meets these requirements is an ideal filtration marker. If the substance is also secreted by the tubules, the clearance exceeds GFR. For those which are reabsorbed by tubules, clearance is less than GFR (Fig.27.1).

Exogenous markers are inulin, \(^{51}\text{Cr}\)-labelled EDTA, \(^{99}\text{Tec}\)-labelled EDTA, etc. These are not used in clinical practice, since it involves administration of extraneous compounds.

Endogenous markers are urea and creatinine. None of these markers are ideal, but creatinine is the best out of all of them.

**Creatinine Clearance Test**

1. **Importance of Creatinine Clearance**
   
   i. Creatinine is a waste product, formed from creatine phosphate (Fig. 15.5). This conversion is spontaneous, non-enzymatic, and is dependent on total muscle mass of the body. It is not affected by diet, age or exercise. Women and children excrete less creatinine than men, because of their smaller muscle mass. 98% of creatine pool is in muscle. About 1.6% is converted to creatinine per day which is rapidly excreted (see Box 27.4).
   
   ii. Since the production is continuous, the blood level will not fluctuate much, making creatinine an ideal substance for clearance test.
   
   iii. Creatinine excretion is constant in a particular person. Hence the urine creatinine is sometimes used to check whether the 24 hr urine sample does actually contain total urine volume or not. This is important when urine is collected from children and mentally retarded persons.
   
   iv. In order to circumvent the difficulty of urine collection, nowadays it is customary to express urinary concentration of other substances per gram of creatinine rather than per 24 hrs urine.

2. **Reference Values of Creatinine**

   - Adult males, 0.7-1.4 mg/dl
   - Adult females, 0.6-1.3 mg/dl
   - Children, 0.4-1.2 mg/dl

   The kidney reserve is such that about 50% kidney function must be lost before creatinine level in blood is raised. Serum level usually parallels the severity of the disease.
Chapter 27; Kidney Function Tests

Box 27.4. Advantages and Disadvantages of using Creatinine Clearance Test as a GFR Marker

**Advantages**
1. Extra-renal factors will rarely interfere.
2. Conversion of creatine phosphate to creatinine is spontaneous, non-enzymatic.
3. As the production is continuous, the blood level will not fluctuate. Blood may be collected at any time.
4. It is not affected by diet or exercise.

**Disadvantages**
1. Creatinine is filtered by glomeruli, and actively excreted by the tubules. Of the total excretion, about 10% is tubular component. When the GFR is reduced, the secretion component is increased, and will viciate the results. The creatinine clearance is said to overestimate GFR by about 10-20 ml/mt.
2. When GFR is severely reduced, extra-renal excretion increases. Then the major route becomes the degradation by intestinal bacterial flora.
3. Very early stages of decrease in GFR may not be identified by creatinine clearance (creatinine blind area).
4. Other pre-renal, renal and post-renal causes will influence creatinine clearance (see under urea clearance).

**Creatinine level more than 1.5 mg/dl indicates impairment of renal function.** Creatinine is quantitated by Jaffe’s reaction where creatinine gives an orange color with alkaline picrate. Test kit based on specific enzymatic reaction is also available.

3. Procedure for Creatinine Clearance Test
Give 500 ml of water to the patient, to promote good urine flow. After about 30 minutes, ask to empty the bladder and discard the urine. Exactly after 60 minutes, again void the bladder and collect the urine, and note the volume. Take one blood sample. Creatinine level in blood and urine are tested and calculated.

Uncorrected clearance = (U/P) x V

where U is the urine creatinine concentration, P is the plasma creatinine concentration and V is the urine flow in ml/min (The 24 hrs urine collection is not necessary for the creatinine clearance test).

It is useful to correct the clearance value with body surface area. This is important, especially in children, and persons with short or tall frame. Creatinine clearance corrected for surface area could be calculated as

\[
\frac{U \times V \times 1.73}{P \times A}
\]

Reference values for creatinine level in blood and the creatinine clearance are shown in Table 27.10. When corrected for surface area, the creatinine clearance value will become comparable between males, females and children, which is about 100 ml/min/1.73 sq meter.

4. Interpretation of Creatinine Clearance
i. A decreased creatinine clearance is a very sensitive indicator of reduced glomerular filtration rate. Factors which will alter the creatinine level are indicated in Table 27.11.
ii. Clearance value up to 75% of the average normal value may indicate adequate renal function. In older people, the clearance is decreased.

iii. The importance of creatinine clearance is in the early detection of functional impairment of kidney without overt signs and symptoms. Changes in plasma creatinine which may not apparently indicate abnormal function may show gross changes in the value of clearance. For example, suppose the plasma creatinine level is 1 mg/dl and the clearance is 100 ml/minute. A rise in plasma creatinine by another mg (=2 mg/dl) will decrease the clearance value by 50%. Other substances will not show such a drastic drop in the clearance values.

iv. The test is very helpful in long-term monitoring of patients with renal insufficiency (ups and downs) under a protein restricted diet.

5. Estimated GFR (eGFR)
A simpler technique of estimating creatinine clearance and thereby GFR is by using serum creatinine level. This would eliminate the need for timed urine collections. A commonly used formula is Cockcroft-Gault equation.

\[ Ccr = \frac{(140-\text{age in years}) \times \text{weight in kg} (0.85 \text{ in females})}{72} \times \text{Pcr} \text{ in mg/dl} \]

The factor 0.85 is used in females assuming that they have 15% less muscle mass. The issue of overestimation cannot be eliminated by this calculation.

A more recent equation used in the MDRD (Modification of Diet in Renal Disease) study is more accurate. This equation directly estimates GFR.

\[ \text{The estimated GFR (eGFR) (ml/min/1.73 m^2)} = \frac{186 \times (\text{Creatinine/88.4}) - 1.154 \times (\text{Age}) - 0.203 \times 0.742 \text{ (if female)}}{1} \]

eGFR can only be used accurately in patients with chronic kidney disease and neither in healthy individuals, nor in children and obese people. The accuracy of plasma creatinine estimation is a major deciding factor in both equations.

6. Creatinine coefficient
It is the urinary creatinine expressed in mg/kg body weight. The value is elevated in muscular dystrophy. Normal range is 20–28 mg/kg for males and 15–21 mg/kg for females.

Cystatin C as a filtration marker
It is a marker which has advantages over serum creatinine. Cystatin C is a 13 kD (120 amino acids) non-glycosylated protein. Normal blood level of cystatin is 0.8 to 1.2 mg/L. It is seen in high concentrations in biological fluids, such as breast milk, tears and saliva. It is expressed in virtually all organs of the body. It is the most abundant extracellular Cysteine protease inhibitors.

Creatinine is the most widely used biomarker of kidney function. But sometimes, it is inaccurate in detecting mild renal impairment. The tubular secretion contributes approximately 10% of the total creatinine excretion by the kidney, and this contribution can increase as GFR decreases. Serum creatinine does not increase until the GFR has moderately decreased. This insensitivity to moderate decreases in GFR is called creatinine blind GFR area (40–70 ml/min/1.73 m²). So, serum creatinine may not be a good parameter for determination of GFR, especially at lower levels of glomerular function.

On the other hand, Cystatin C is produced at a constant rate and is freely filtered by kidney glomeruli. It is completely reabsorbed; but degraded in the tubules; thus making it an excellent GFR marker. The blood levels are not dependent on age, sex, muscle mass or inflammatory processes. It is sensitive to changes in the so-called creatinine blind area of GFR(40–70 ml/min/ 1.73 m²). So, serum level of cystatin is a better test for kidney function (GFR) than serum creatinine levels. Since there is no tubular secretion of Cystatin C, it is extremely sensitive to minor changes in GFR in the earliest stages of chronic kidney diseases.

Chronic kidney disease (CKD)
GFR < 60 ml/min/1.73 m² for 3 months or more with or without kidney damage indicates CKD. GFR calculated from serum creatinine and MDRD equation is used to grade CKD (Table 27.12)

Urea Clearance Test

1. Importance of Urea Clearance
The urea clearance is less than GFR, because urea is partially reabsorbed (Fig. 27.1). Urea clearance is the number of ml of blood which contains the urea excreted in a minute by kidneys.

2. Procedure
Allow the patient to have a normal breakfast. At 9 am give a cup of water and the patient is instructed to...
void the bladder, and urine is discarded. At 10 am bladder is completely emptied and the volume of urine is measured and the urine urea is estimated. A blood sample is taken and blood urea is also estimated.

3. Maximum Urea Clearance

The urea clearance is calculated by the formula

\[ \frac{U \times V}{P} \]

where \( U \) = mg of urea per ml of urine; \( P \) = mg of urea per ml of plasma and \( V \) = ml of urine excreted per minute. This is called maximum urea clearance and the normal value is found to be 75 ml/minute.

4. Standard Urea Clearance

But the clearance value is decreased when \( V \), the volume of urine, is less than 2 ml/minute. Then it is called standard urea clearance, where the normal value is found to be 54 ml/minute, and is calculated as:

\[ \frac{U \times \sqrt{V}}{P} \]

5. Interpretation of Urea Clearance Value

i. If the value is below 75% of the normal, it is considered to be abnormal. The values fall progressively with failing renal function.

ii. The clearance value may be abnormal even though the plasma urea values are within normal limits. The plasma urea values will start to rise only when the clearance value falls below 50% of the normal.

iii. Urea is normally reabsorbed from renal tubules and therefore tubular function also affects urea clearance. Hence, creatinine clearance test is more preferred.

iv. Urea is freely filtered by the glomerulus and passively reabsorbed in both PCT and DCT. Urea clearance is less than GFR (Fig. 27.1).

Blood Urea Level

1. Normal Serum Urea Level

i. Normal value is 20 to 40 mg/dl. Estimation of urea is done by enzymatic method using urease and glutamate dehydrogenase.

ii. Serum urea is sometimes expressed in terms of its nitrogen, because nitrogenous substances were analyzed by Kjeldahl method. Such expression of Urea-N or blood urea nitrogen (BUN) is very common in USA. Molecular weight of urea is 60 and each g.mol of urea contains 28 g of nitrogen. Thus a serum concentration of 28 mg/dl of BUN is equivalent to 60 mg/dl of urea or 10 mmol/L of urea. BUN can be converted into urea by multiplying the figure by 2.14.

2. Interpretation of Blood Urea Value

Urea is the end-product of protein metabolism (Chapter 14). The serum concentration of urea generally increases as the age advances. The lower range is usually seen in young adults and the upper limit is normal for elderly people. Therefore a value of 40 mg/dl in a patient of 25 years may be considered as suspicious, while the same value in a person of 60 years can be considered as perfectly normal. Causes for increased blood urea are enumerated in Box 27.5.

3. Renal Diseases

i. Serum urea is increased in all forms of kidney diseases. In acute glomerulonephritis values may be as high as 300 mg/dl.

ii. In early stages of nephrosis, serum urea may be normal, but in late stages serum urea increases along with decreasing renal functions.

iii. In malignant hypertension and in chronic pyelonephritis, the values may reach very high levels. Pre-renal and post-renal causes are shown in Box 27.5.
**4. Decreased Blood Urea**

Urea concentration in serum may be low in late pregnancy, in starvation, in diet grossly deficient in proteins and in hepatic failure.

**Azotemia**

Increase in the blood levels of NPN is referred to as azotemia and is the hallmark of kidney failure. BUN/Creatinine ratio can be used as a discriminator between pre-renal and post-renal azotemia. A normal adult on a normal diet has a ratio between 12-20 mg BUN/mg of creatinine. Lower ratios denote acute renal tubular necrosis, low protein intake, starvation and severe liver disease. High plasma urea with normal creatinine and high BUN/creatinine ratio indicates pre-renal azotemia. High ratios with high urea and creatinine suggests post-renal obstruction or pre-renal azotemia superimposed on CKD.

**Uremic syndrome**

It is the terminal manifestation of renal failure. The effects of a group of toxins contribute to this situation. Increased urea will lead to carbamoylation of proteins; increased uric acid causes uremic pericarditis; excess polyols is the basis of peripheral neuropathy; Beta -2 microglobulin is the reason for renal amyloidosis. When renal function fails, the assessment of residual renal function is done by a variety of tests (Box 27.6).

**Inulin clearance**

Inulin is a polysaccharide of fructose. It is not appreciably metabolized by the body. It is neither absorbed nor secreted by the tubules. Therefore, inulin clearance is a measure of GFR. The value of GFR as measured by inulin clearance is 125 ml/minute. About 100 ml of sterile 10% solution of inulin is given as slow intravenous drip within 2 hours. Urine specimen formed during this period is collected totally. Blood sample is taken at the middle of the test. Inulin is estimated by resorcinol giving a red color. The test needs continuous infusion of inulin so as to keep the plasma level adequate. Since it involves administration of an extraneous compound, this procedure is not used routinely.

\[
\text{inulin clearance (GFR)} = 125 \text{ ml/min and urea clearance} = 75 \text{ ml/min. Therefore,}
\]

\[
\frac{\text{inulin clearance minus urea clearance}}{\text{glomerular filtration rate}} = \frac{125 - 75}{125} = 0.4
\]

In other words, 40% of urea present in the glomerular filtrate is reabsorbed in the tubules.

**Box 27.6. Parameters for Residual Renal Function**

- **Excretory function**: NPN – Plasma levels of urea, creatinine, uric acid
- **Endocrine function**: Hemoglobin, calcium and phosphate
- **Homeostasis**: pH and electrolytes; sodium, potassium, bicarbonate and Chloride

**MARKERS OF GLOMERULAR PERMEABILITY**

The glomerulus acts as a selective filter of the blood passing through its capillaries. Passage of macromolecules is restricted based on their charge, size and shape. Molecules smaller than 5 kD, such as urea, glucose, creatinine and electrolytes are freely filtered by the glomerulus. The glomerular membrane is such that albumin (mol.wt. 69 kD) is retained in the blood, but free hemoglobin (mol.wt. 67 kD) is filtered and excreted in urine.

The low molecular weight proteins are freely filtered, reabsorbed and catabolized by renal tubular cells. Normal urinary protein excretion is less than 150 mg/24 hours, made up of mostly albumin (5 mg/L), Tamm Horsfall glycoprotein and alpha-1 microglobulin (5 mg/L). The urine protein estimations are done by immunochromat methods. The appearance of significant quantities of proteins like albumin indicates increased glomerular permeability.

**Proteinuria**

It may be of the following types:

a. **Increase in filtered load due to glomerular damage and vascular permeability**- This is called glomerular proteinuria.

b. **Increased circulating concentration of low molecular weight proteins**- (Overflow proteinuria)

c. **Decrease in reabsorptive capacity due to tubular damage**- (Tubular proteinuria).

**1. Glomerular proteinuria**

The glomeruli of kidney are not permeable to substances with molecular weight more than 69,000 and so plasma proteins are absent in normal urine. When glomeruli are damaged or diseased, they become more permeable and plasma proteins may...
325

appear in urine. The smaller molecules of albumin pass through damaged glomeruli more readily than the heavier globulins. Albuminuria is always pathological. Large quantities (a few grams per day) of albumin are lost in urine in nephrosis. Small quantities are seen in urine in acute nephritis, strenuous exercise and pregnancy.

Overnight first voided sample (early morning urine-EMU) may be used for the measurement of protein. An EMU is preferred since it rules out the possibility of orthostatic albuminuria. Protein creatinine ratio is calculated to decide whether the patient has nephrotic range proteinuria (>3.5) or not. The calculation of ratios is found to give better predictability of chronic kidney disease (CKD).

Detection limit with Dipstick is 200-300 mg/L. 300 mg/day = Benign proteinuria 300 mg -1000 mg = Pathological proteinuria > 1000 mg/day = Glomerular proteinuria

Indications for quantitation are shown in Box 27.7.

2. Micro-albuminuria
It is also called minimal albuminuria or pauci-albuminuria. It is identified, when small quantity of albumin (30-300 mg/day) is seen in urine. The test is not indicated in patients with overt proteinuria (+ve dipstick). Early morning midstream sample is preferred.

Micro albuminuria is an early indication of nephropathy in patients with diabetes mellitus and hypertension. Hence, all patients who are known diabetics and hypertensive should be screened for microalbuminuria. It is an early indicator of onset of nephropathy. The test should be done at least once in an year.

It is expressed as albumin-creatinine ratio; normal ratio being

Patients showing higher values on more than one occasions are considered to have microalbuminuria. Confirmed by overnight urine collection and calculation of albumin excretion rate. A value more than 20 microgram/minute confirms microalbuminuria. Administration of ACE inhibitors decreases the rate of microalbuminuria.

The selectivity of the membrane provides an assessment of glomerular damage. Protein selectivity index is the relative proportion of higher to lower molecular weight protein (see Box 27.8). Micro-albuminuria is detected by radial immunodiffusion or by enzyme linked immunosorbent methods.

3. Overflow Proteinuria
When small molecular weight proteins are increased in blood, they overflow into urine. For example, hemoglobin having a molecular weight of 67,000 can pass through normal glomeruli, and therefore, if it exists in free form (as in hemolytic conditions), hemoglobin can appear in urine (hemoglobinuria).
Similarly, myoglobinuria is seen following muscle crush injury.

Yet another example is the Bence-Jones proteinuria. In about 20% cases of multiple myeloma (plasmacytoma), the light chains of immunoglobulins are produced abnormally. Being of smaller molecular weight, they are excreted in urine. These are called Bence-Jones Proteins (monoclonal light chains produced by plasmacytomas) (Chapter 49). When the urine is heated, at 45°C they start precipitating, at 60°C there is maximum precipitation, at 80°C these proteins start re-dissolving, and will form a clear solution at 100°C. The precipitate re-forms on cooling. It is also detected by immunoprecipitation.

4. Tubular Proteinuria
This occurs when functional nephrons are reduced, GFR is decreased and remaining nephrons are over-working. The tubular reabsorption mechanism is impaired, so low molecular weight proteins appear in urine. They are Retinol binding protein (RBP) and alpha-1 microglobulin (Protein HC). Both are synthesized in liver and are readily filtered by the glomerulus. Tubular damage results in the release of intracellular components to the urinary tract and may be used as markers of tubular damage e.g. beta-D-glucosaminidase, lysozyme.

5. Nephron Loss Proteinuria
In CKD, there is a decrease in the number of functioning nephrons. The compensatory rise in glomerular filtration by other nephrons increases the filtered load of proteins. Even if there are no glomerular permeability changes, tubular proteinuria is seen.

6. Urogenic proteinuria
This is due to inflammation of lower urinary tract, when proteins are secreted into the tract. Accumulation of proteins in tubular lumen can trigger inflammatory reaction.

TESTS FOR TUBULAR FUNCTION

1. Specific Gravity of Urine
The simplest test of tubular function is the measurement of the specific gravity (SG) of urine. This is an indication of osmolality.

Specific gravity depends on the concentration of solutes, whereas osmolality depends on the number of osmotically active particles. Hence in cases of proteinuria, the specific gravity is elevated considerably, but osmolality is only mildly elevated.

In moderate forms of kidney damage, the blood level of urea and creatinine may be within the normal limits. The inability to excrete the waste products may be counterbalanced by large urine output. Thus the earliest manifestation of renal disease may be difficulty in concentrating the urine.

2. Measurement of Osmolality
The osmolality of urine samples vary widely from (60 milliosmol/kg to 1200 milliosmol/kg). A random urine sample may have an osmolality around 600 mosmls/kg and it increases to 850 after 12 hours fluid restriction. Simultaneous measurements of plasma and urine osmolality and calculation of the ratio of osmolality of urine/plasma is more helpful. Normally the ratio varies from 3-4.5. The normal value of plasma osmolality is 285–300 mosm/kg. Osmolality is measured with an osmometer based on the depression of the freezing point of the sample. Patients with deficiency of ADH (Central diabetes insipidus) or a decreased response to ADH (Nephrogenic diabetes insipidus) will excrete urine with osmolality less than 300 mosmols/kg (Table 27.13).

3. Concentration Test
i. The patient is allowed no food or water after a meal at 6 pm. The next day at 7 AM, the bladder is emptied and specimen is discarded. A second specimen is collected at 8 am and the specific gravity is measured.

ii. If the specific gravity is more than 1.022 (osmolality exceeds 850 milliosmol/kg), the patient has adequate renal function.

iii. In normal persons, the SG may be as high as 1.032. During the concentration test osmolality should exceed 750 milliosmol/kg.

iv. As the disease progresses the urine specific gravity is fixed at and around 1.010 (300 milliosmol/kg)). It is then called isosthenuria.

v. The measurement of the volume of urine excreted during the day and the night is another simple index of tubular function. Normally night volume is only half of the day volume. But an increased excretion of urine at night or nocturia is an early indication of tubular dysfunction.

6. Fractional excretion of bicarbonate

\[ \text{FE}_{\text{HCO}_3} = \frac{(\text{Urine \ [HCO}_3^-] \times \text{Plasma \ [Creatinine]})/\text{(Plasma \ [HCO}_3^-] \times \text{Urine \ [Creatinine])}}{\times 100. \ \text{Normal \ FE}_{\text{HCO}_3} \text{is} < 15\%}. \]  

A level of > 20% confirms Type 2 (proximal) renal tubular acidosis.

7. Fractional Excretion of Sodium (FENa)

It is the sodium clearance as a % of creatinine clearance. It is calculated as \( \frac{\text{UNa}}{\text{PNa} \times \text{Ucr}} \times \text{Pcr} \times 100 \)

When tubular conservation of Na is lost, FENa increases to greater than 3% of Ccr. FeNa is <35% in pre-renal and >50% in acute tubular necrosis. During hypovolemia, FeNa decreases to less than 1% of Ccr. A spot urine sample drawn at the same time is used for sodium and creatinine estimation.

8. Fractional Excretion of Phosphate (FE_{PO_4})

It is used in the diagnosis of hypophosphatemia (e.g., X-linked hypophosphatemic rickets).

\[ \text{Fractional phosphate excretion (FE}_{\text{PO}_4} = \frac{\text{C}}{\text{C}} = \left(\frac{\text{Serum \ [Creatinine] \times \text{Urine \ [Phosphate]}}}{\text{(Urine \ [Creatinine] \times \text{Urine \ [Phosphate])}}}\right) \]

**Fractional tubular reabsorption of phosphate (TRP)** is calculated as \( 1 - \text{FE}_{\text{PO}_4} \)

**Tubular maximum for phosphate reabsorption (TmP/GFR)** can be calculated as

- If TRP < 0.86, \( \text{TmP/GFR} = \text{TRP} \times \text{Plasma P} \).
- If TRP > 0.86, \( \text{TmP/GFR} = \{0.30 \times \text{TRP}/(1 - (0.8 \times \text{TRP}))\} \times \text{Plasma Phosphate} \).

Adult normal range for TmP/GFR is 0.80-1.35 mmol/L.

Higher normal values are seen in children and infants. Low values are classically seen in X-linked hypophosphatemic rickets and in osteogenic osteomalacia. Both disorders are due to over-production or failure of inactivation of phosphatonin, a phosphaturic hormone.

TmP/GFR is increased in hypopopara-thyroidism. TmP/GFR is decreased in hyperpara-thyroidism Reduced phosphate reabsorption seen in hyper calcuiuric stone formers as well as in other primary and secondary disorders of renal tubular function.

A summary of renal function tests is shown in Table 27.14.

### Immunological Tests in Renal Diseases

Tests done include:

1. Complement components
2. Immunoglobulins and serum electrophoresis for para-proteinemias
3. Cryoglobulins
4. Anti-neutrophil cytoplasmic antibodies (ANCA)
5. Anti-GBM antibody
6. Free light chain assay with kappa: lambda ratio
Findings of complement tests are shown in Table 27.15. Indications of testing complement are:

1. Acute nephritis syndrome
2. Renal failure with skin/neurological involvement
3. Suspected SLE
4. Endocarditis
5. Cryoglobulinemia

Cryoglobulinemia
These are immunoglobulins precipitated on cooling, and redissolving on warming. Box 27.9 shows the conditions in which cryoglobulinemia are associated. Test for cryoglobulinemia is done in:

1. Renal failure with unexplained hypocomplementemia or positive rheumatoid factor
2. Renal failure in association with skin and neurological involvement
3. Unexplained renal failure and proteinuria in patients
4. Raynaud-like symptoms due to complexes blocking blood vessels

Anti-Neutrophil Cytoplasmic Antibody (ANCA)
Auto-antibodies directed against enzymes present in cytoplasm of human neutrophils. They are seen in all patients with small vessel vasculitis like Wegener's granulomatosis, microscopic polyangiitis and crescentic glomerulonephritis. Negative ANCA does not rule out vasculitis, and false positive may also occur. Immunofluorescence is used to detect these antibodies. It is positive in small vessel vasculitis. Non-specific ANCA elevation may be seen in systemic infections and other auto-immune diseases.

Anti-Glomerular Basement Membrane Antibody
Anti-GBM antibody is seen in acute nephritic syndrome as well as in Goodpasture’s syndrome, where autoantibody against type IV collagen is found in the glomerular basement membrane and lungs. It causes rapidly progressive GN and lung hemorrhage. A negative test does not rule out disease, and renal biopsy may be needed.
Total blood volume is about 4.5 to 5 liters in adult human being. If blood is mixed with an anticoagulant and centrifuged, the cell components (RBC and WBC) are precipitated. The supernatant is called plasma. About 55-60% of blood is made up of plasma.

i. If blood is withdrawn without anticoagulant and allowed to clot, after about 2 hours liquid portion is separated from the clot. This defibrinated plasma is called serum, which lacks coagulation factors including prothrombin and fibrinogen.

ii. Total protein content of normal plasma is 6 to 8 g/100 ml.

iii. The plasma proteins consist of albumin (3.5 to 5 g/dl), globulins (2.5-3.5 g/dl) and fibrinogen (200-400 mg/dl). The albumin:globulin ratio is usually between 1.2:1 to 1.5:1.

iv. Almost all plasma proteins, except immunoglobulins are synthesized in liver. Plasma proteins are generally synthesized on membrane-bound polyribosomes. Most plasma proteins are glycoproteins.

v. In laboratory, separation can be done by salts. Thus, fibrinogen is precipitated by 10% and globulins by 22% concentration of sodium sulphate. Ammonium sulphate will precipitate globulins at half saturation and albumin at full saturation.

vi. In clinical laboratory, total proteins in serum or plasma of patients are estimated by Biuret method (Chapter 4). Albumin is quantitated by Bromo cresol green (BCG) method, in which the dye is preferentially bound with albumin, and the color is estimated colorimetrically.

**ELECTROPHORESIS**

In clinical laboratory, electrophoresis is employed regularly for separation of serum proteins. The term electrophoresis refers to the movement of charged particles through an electrolyte when subjected to an electric field. The details are given in Chapter 54. Normal and abnormal electrophoretic patterns are shown in Figures 28.1 and 28.2.

**Normal Patterns and Interpretations**

i. In agar gel electrophoresis, normal serum is separated into 5 bands. Their relative concentrations are given below:

![Serum electrophoretic patterns](image)

**Fig. 28.1. Serum electrophoretic patterns**
**Abnormal Patterns in Clinical Diseases**

Various abnormalities can be identified in the electrophoretic pattern (Fig. 28.1).

1. **Chronic infections:** The gamma globulins are increased, but the increase is smooth and wide-based.

2. **Multiple myeloma:** In para-proteinemias, a sharp spike is noted and is termed as M-band. This is due to monoclonal origin of immunoglobulins in multiple myeloma (Fig. 28.2).

3. **Fibrinogen:** Instead of serum, if plasma is used for electrophoresis, the fibrinogen will form a prominent band in the gamma region, which may be confused with the M-band.

4. **Primary immune deficiency:** The gamma globulin fraction is reduced.

5. **Nephrotic syndrome:** All proteins except very big molecules are lost through urine, and so alpha-2 fraction (containing macroglobulin) will be very prominent.

6. **Cirrhosis of liver:** Albumin synthesis by liver is decreased, with a compensatory excess synthesis of globulins by reticulo-endothelial system. So albumin band will be thin, with a wide beta fraction; sometimes beta and gamma fractions are fused.

7. **Chronic lymphatic leukemia:** Gamma globulin fraction is reduced.

8. **Alpha-1-antitrypsin deficiency:** The alpha-1 band is thin or even missing.

**ALBUMIN**

i. The name is derived from the white precipitate formed when egg is boiled (Latin, albus = white). Albumin constitutes the major part of plasma proteins.

ii. It has one polypeptide chain with 585 amino acids. It has a molecular weight of 69,000 D. It is elliptical in shape.

iii. It is synthesized by hepatocytes; therefore estimation of albumin is a liver function test (Chapter 26). Albumin is synthesized as a precursor, and the signal peptide is removed as it passes through endoplasmic reticulum.

iv. Albumin can come out of vascular compartment. So albumin is present in CSF and interstitial fluid.

v. Half-life of albumin is about 20 days. Liver produces about 12 g of albumin per day, representing about 25% of total hepatic protein synthesis.

**Half-life:** Each plasma protein has a characteristic half-life in circulation; e.g. half-life of albumin is 20 days, and that of haptoglobin is 5 days. The half-life is studied by labeling the pure protein with radioactive chromium (\(^{51}\)Cr). A known quantity of the labeled protein is injected into a normal person, and blood samples are taken at different time intervals. Half-life of a protein in circulation may be drastically reduced when proteins
Chapter 28; Plasma Proteins

Functions of Albumin

1. Colloid osmotic pressure of plasma
   i. The total osmolality of serum is 278-305 m osmol/kg (about 5000 mm Hg). But this is produced mainly by salts, which can pass easily from intravascular to extravascular space. Therefore, the osmotic pressure exerted by electrolytes inside and outside the vascular compartments will cancel each other. But proteins cannot easily escape out of blood vessels, and therefore, proteins exert the ‘effective osmotic pressure’. It is about 25 mm Hg, and 80% of it is contributed by albumin. The maintenance of blood volume is dependent on this effective osmotic pressure.
   ii. According to Starling’s hypothesis, at the capillary end the blood pressure (BP) or hydrostatic pressure expels water out, and effective osmotic pressure (EOP) takes water into the vascular compartment (Fig. 28.3).
   iii. At arterial end of the capillary, BP is 35 mm Hg and EOP is 25 mm; thus water is expelled by a pressure of 10 mm Hg. At the venous end of the capillary, EOP is 25 mm and BP is 15 mm, and therefore water is imbibed with a pressure of 10 mm. Thus the number of water molecules escaping out at arterial side will be exactly equal to those returned at the venous side and therefore blood volume remains the same.
   iv. If protein concentration in serum is reduced, the EOP is correspondingly decreased. Then return of water into blood vessels is diminished, leading to accumulation of water in tissues. This is called edema.

2. Transport Function
   Albumin is the carrier of various hydrophobic substances in the blood. Being a watery medium, blood cannot solubilize lipid components.
   i. Bilirubin and nonesterified fatty acids are specifically transported by albumin.
   ii. Drugs (sulpha, aspirin, salicylate, dicoumarol, phenytoin),
   iii. Hormones: steroid hormones, thyroxine
   iv. Metals: Albumin transports copper. Calcium and heavy metals are non-specifically carried by albumin. Only the unbound fraction of drugs is biologically active.

3. Buffering action
   All proteins have buffering capacity. Because of its high concentration in blood, albumin has maximum buffering capacity (Chapter 29). Albumin has a total of 16 histidine residues which contribute to this buffering action.

4. Nutritional function
   All tissue cells can take up albumin by pinocytosis. It is then broken down to amino acid level. So albumin may be considered as the transport form of essential amino acids from liver to extrahepatic cells. Human albumin is clinically useful in treatment of liver diseases, hemorrhage, shock and burns.

Clinical Applications

1. Blood brain barrier
   Albumin–fatty acid complex cannot cross blood–brain barrier and hence fatty acids cannot be taken up by brain. The bilirubin from albumin may be competitively replaced by drugs like aspirin. Being lipophilic, unconjugated bilirubin can cross the blood brain barrier and get deposited in brain. The brains of young children are susceptible; free bilirubin deposited in brain leads to kernicterus and mental retardation (Chapter 21).

2. Drug interactions
   When two drugs having high affinity to albumin are administered together, there may be competition for the available sites, with consequent displacement of one drug. Such an effect may lead to clinically
significant drug interactions, e.g. phenytoin – dicoumarol interaction.

3. **Protein-bound calcium**
   Calcium level in blood is lowered in hypo-albuminemia. Thus, even though total calcium level in blood is lowered, ionized calcium level may be normal, and so tetany may not occur (Chapter 35). Calcium is lowered by 0.8 mg/dl for a fall of 1 g/dl of Albumin.

4. **Therapeutic use**
   Human albumin is therapeutically useful to treat burns, hemorrhage and shock.

5. **Edema**
   Hypo-albuminemia will result in tissue edema (see Starling’s law).
   - **Malnutrition**, where albumin synthesis is depressed (generalized edema)
   - **Nephrotic syndrome**, where albumin is lost through urine (facial edema)
   - **Cirrhosis** of liver (mainly ascites), where albumin synthesis is less and it escapes into ascitic fluid.
   - **Chronic congestive cardiac failure**: Venous congestion will cause increased hydrostatic pressure and decreased return of water into capillaries and so pitting edema of feet may result.

6. **Normal value**
   Normal level of Albumin is 3.5–5 g/dl. Lowered level of albumin (hypo-albuminemia) has important clinical significance.

7. **Hypo-albuminemia**
   - **Cirrhosis of liver**: Synthesis is decreased.
   - **Malnutrition**: Availability of amino acids is reduced and albumin synthesis is affected.
   - **Nephrotic syndrome**: Permeability of kidney glomerular membrane is defective, so that albumin is excreted in large quantities.
   - **Albuminuria**: Presence of albumin in urine is called albuminuria. It is always pathological. Large quantities (a few grams per day) of albumin are lost in urine in nephrotic syndrome. Small quantities are lost in urine in acute nephritis, and other inflammatory conditions of urinary tract. Detection of albumin in urine is done by heat and acetic acid test (see Chapter 27). In micro-albuminuria or minimal albuminuria or pauci-albuminuria, small quantity of albumin (30-300 mg/d) is seen in urine (Paucity = small in quantity).
   - **Protein losing enteropathy**: Large quantities of albumin is lost from intestinal tract.
   - **Analbuminemia** is a very rare condition, where defective mutation in the gene is responsible for absence of synthesis.

   **Albumin-Globulin Ratio**
   In hypo-albuminemia, there will be a compensatory increase in globulins which are synthesized by the reticulo-endothelial system. Albumin-globulin ratio (A/G ratio) is thus altered or even reversed. This again leads to edema.

   **Hypoproteinemia**
   Since albumin is the major protein present in the blood, any condition causing lowering of albumin will lead to reduced total proteins in blood (hypoproteinemia).

   **Hyper-gamma-globulinemias**
   1. **Low albumin level**
      When albumin level is decreased, body tries to compensate by increasing the production of globulins from reticulo-endothelial system.

   2. **Chronic infections**
      Gamma globulins are increased, but the increase is smooth and wide based (Fig. 28.1).

   3. **Multiple myeloma**
      Drastic increase in globulins is seen in para-proteinemias, when a sharp spike is noted in electrophoresis. This is termed as M-band because of the monoclonal origin of immunoglobulins (Figs 28.1 and 28.2). The monoclonal origin of immunoglobulins is seen in multiple myeloma (Chapter 49). Monoclonal gammopathies are characterized by the presence of a monoclonal protein which can be detected by serum protein electrophoresis and typed by immunofixation electrophoresis. The light chains are produced in excess which is excreted in urine as Bence Jones proteins (BJP) when their serum level increases. Multiple myeloma is the most common type of monoclonal gammopathy. Free light chain assay along with kappa and lambda ratio in serum and urine is found to be very useful in early diagnosis, monitoring the response to treatment and prediction of prognosis.
Blood is a watery medium; so lipids and lipid soluble substances will not easily dissolve in the aqueous medium of blood. Hence, such molecules are carried by specific carrier proteins. Their important features are summarized in Table 28.1.

1. **Albumin**: It is an important transport protein, which carries bilirubin, free fatty acids, calcium and drugs (see above).

2. **Pre-albumin or Transthyretin**: It is so named because of its faster mobility in electrophoresis than albumin. It is more appropriately named as **Transthyretin** or **Thyroxine binding pre-albumin (TBPA)**, because it carries thyroid hormones, thyroxin (T₄) and tri-iodo thyronine (T₃). Its half-life in plasma is only 1 day.

3. **Retinol binding protein (RBP)**: It carries vitamin A (Chapter 33). It is a low molecular weight protein, and so is liable to be lost in urine. To prevent this loss, RBP is attached with pre-albumin; the complex is big and will not pass through kidney glomeruli. It is an acute phase protein.

4. **Thyroxine binding globulin (TBG)**: It is the specific carrier molecule for thyroxine and tri-iodo thyronine. TBG level is increased in pregnancy; but decreased in nephrotic syndrome.

5. **Transcortin**: It is also known as **Cortisol binding globulin (CBG)**. It is the transport protein for cortisol and corticosterone.

6. **Haptoglobin**: Haptoglobin (for hemoglobin), **Hemopexin** (for heme) and **Transferrin** (for iron) are important to prevent loss of iron from body.

---

Polymorphism
The term polymorphism is applied when the protein exists in different phenotypes in the population; but only one form is seen in a particular person. Haptoglobin, transferrin, ceruloplasmin, alpha-1-antitrypsin and immunoglobulins exhibit polymorphism. For example, haptoglobin (Hp) exists in three forms, Hp1–1, Hp2–1, and Hp2–2. Two genes, designated Hp1 and Hp2 are responsible for these polymorphic forms. Their functional capabilities are the same. These polymorphic forms are recognized by electrophoresis or by immunological analysis. Study of polymorphism is useful for genetic and anthropological studies.

ACUTE PHASE PROTEINS
The level of certain proteins in blood may increase 50 to 1000 folds in various inflammatory and neoplastic conditions. Such proteins are acute phase proteins. Important acute phase proteins are described below:

1. C-Reactive Protein (CRP)
So named because it reacts with C-polysaccharide of capsule of pneumococci. CRP is a beta-globulin and has a molecular weight of 115-140 kD. It is synthesized in liver. It can stimulate complement activity and macrophage phagocytosis. When the inflammation has subsided, CRP quickly falls, followed later by ESR (erythrocyte sedimentation rate). CRP level, especially high sensitivity C-reactive protein level in blood has a positive correlation in predicting the risk of coronary artery diseases (Chapter 25).

2. Ceruloplasmin
i. Ceruloplasmin is blue in color (Latin, caeruleus = blue). It is an alpha-2 globulin with molecular weight of 160,000 Daltons. It contains 6 to 8 copper atoms per molecule.

ii. Ceruloplasmin is mainly synthesized by the hepatic parenchymal cells and a small portion by lymphocytes and macrophages. After the formation of peptide part (apo-Cp) copper is added by an intracellular ATPase and carbohydrate side chains are added to make it a glycoprotein (holo-Cp). The normal plasma half-life of holo-Cp is 4-5 days.

iii. Ceruloplasmin is also called Ferroxidase, an enzyme which helps in the incorporation of iron into transferrin (Chapter 35). It is an important anti-oxidant in plasma.

iv. Ninety per cent of copper content of plasma is bound with ceruloplasmin, and 10% with albumin. Copper is bound with albumin loosely, and so easily exchanged with tissues. Hence transport protein for copper is Albumin.

v. Lowered level of ceruloplasmin is seen in Wilson’s disease, malnutrition, nephrosis, and cirrhosis.

vi. Ceruloplasmin is an acute phase protein. Increased plasma Cp levels are seen in active hepatitis, biliary cirrhosis, hemochromatosis, and obstructive biliary disease, pregnancy, estrogen therapy, inflammatory conditions, collagen disorders and in malignancies. Drugs increasing the ceruloplasmin level are estrogen and contraceptives.

Reference blood levels of ceruloplasmin are:
Adults Males- 22-40 mg/dl
Females 25-60 mg/dl
Females on oral contraceptives: 27-66 mg/dl
Pregnancy 30-120 mg/dl

Wilson’s Disease
a. Level is reduced to less than 20 mg/dl in Wilson’s hepatolenticular degeneration. It is an inherited autosomal recessive condition. Incidence of the disease is 1 in 50,000.

b. The basic defect is a mutation in a gene encoding a copper binding ATPase in cells, which is required for excretion of copper from cells. So, copper is not excreted through bile, and hence copper toxicity. Please also see Chapter 35, under copper metabolism.

c. Increased copper content in hepatocyte inhibits the incorporation of copper to apo-ceruloplasmin. So ceruloplasmin level in blood is decreased.

Clinical features
a. Accumulation in liver leads to hepatocellular degeneration and cirrhosis.

b. Deposit in brain basal ganglia leads to lenticular degeneration and neurological symptoms.

c. Copper deposits as green or golden pigmented ring around cornea; this is called Kayser-Fleischer ring.

d. Treatment consists of a diet containing low copper and injection of D-penicillamine which excretes
copper through urine. Since zinc decreases copper absorption, zinc is useful in therapy.

3. **Alpha-1 Anti-trypsin (AAT)**
   It is otherwise called *alpha-anti-proteinase* or *protease inhibitor*. It inhibits all serine proteases (proteolytic enzymes having a serine at their active center), such as plasmin, thrombin, trypsin, chymotrypsin, elastase, and cathepsin. Serine protease inhibitors are abbreviated as Serpins.

   AAT is synthesized in liver. It is a glycoprotein with a molecular weight of 50 KD. It forms the bulk of molecules in serum having alpha-1 mobility. Normal serum level is 75-200 mg/dl. AAT deficiency causes the following conditions:

   **Emphysema**: The incidence of AAT deficiency is 1 in 1000, and is one of the commonest inborn errors. The total activity of alpha1-AT is reduced in these individuals. Bacterial infections in lung attract macrophages which release elastase. In the alpha 1-AT deficiency, unopposed action of elastase will cause damage to lung tissue, leading to emphysema. About 5% of emphysema cases are due to alpha1-AT deficiency.

   **Nephrotic syndrome**: AAT molecules are lost in urine, and so AAT deficiency is produced.

4. **Alpha-2-Macroglobulin (AMG)**
   AMG is a tetrameric protein with molecular weight of 725 kD. It is the major component of alpha-2 globulins. It is synthesized by hepatocytes and macrophages. AMG inactivates all proteases, and is an important *in vivo anti-coagulant*. AMG is the carrier of many growth factors such as platelet derived growth factor (PDGF). Normal serum level is 130-300 mg/dl. Its concentration is markedly increased (up to 2-3 g/dl) in *Nephrotic syndrome*, where other proteins are lost through urine.

**Negative Acute Phase Proteins**

During an inflammatory response, some proteins are seen to be decreased in blood; those are called negative acute phase proteins. Examples are *albumin, transthyretin (pre-albumin), retinol binding protein and transferrin*.

Transferrin is a specific iron binding protein (see Chapter 35). It has a half-life of 7-10 days and is used as a better index of protein turnover than albumin.
Plasma contains many enzymes (Chapter 23), protein hormones (Chapter 45) and immunoglobulins (Chapter 49). A comprehensive list of reference values for the substances present in blood is given in the Appendix II.

CLOTTING FACTORS
The word coagulation is derived from the Greek term, "coagulare" = to curdle. The biochemical mechanism of clotting is a typical example of cascade activation.

The coagulation factors are present in circulation as inactive zymogen forms. They are converted to their active forms only when the clotting process is initiated. This would prevent unnecessary intravascular coagulation. Activation process leads to a cascade amplification effect, in which one molecule of preceding factor activates 1000 molecules of the next factor. Thus within seconds, a large number of molecules of final factors are activated. The clotting process is schematically represented in Fig. 28.4 and the characteristics of coagulation factors are shown in Table 28.2.

Several of these factors require calcium for their activation. The calcium ions are chelated by the gamma carboxyl group of glutamic acid residues of the factors, prothrombin, VII, IX, X, XI and XII. The gamma carboxylation of glutamic acid residues is dependent on vitamin K (Chapter 33), and occurs after synthesis of the protein (post-translational modification).

Prothrombin
It is a single chain zymogen with a molecular weight of 69,000 D. The plasma concentration is 10-15
mg/dl. The prothrombin is converted to thrombin by Factor Xa, by the removal of N-terminal fragment.

**Thrombin**

It is a serine protease with molecular weight of 34,000 D. The Ca²⁺ binding of prothrombin is essential for anchoring the prothrombin on the surface of platelets. When the terminal fragment is cleaved off, the calcium binding sites are removed and so, thrombin is released from the platelet surface.

**Fibrinogen**

The conversion of fibrinogen to fibrin occurs by cleaving of Arg-Gly peptide bonds of fibrinogen. Fibrinogen has a molecular weight of 3,40,000 D and is synthesized by the liver. Normal fibrinogen level in blood is 200-400 mg/dl. The fibrin monomers formed are insoluble. They align themselves lengthwise, aggregate and precipitate to form the clot. Fibrinogen is an **acute phase protein**.

**Prothrombin Time (PT)**

PT evaluates the extrinsic coagulation pathway, so that if any of the factors synthesized by the liver (factors I, II, V, VII, IX and X) is deficient prothrombin time will be prolonged. It is the time required for the clotting of whole blood (citrated or oxalated) after addition of calcium and tissue thromboplastin. So, fibrinogen is polymerized to fibrin by thrombin.

PT is commonly assessed by the "one stage" prothrombin time of Quick (named after the inventor). The results are expressed either in seconds or as a ratio of the plasma prothrombin time to a control plasma time. The normal control PT is 9-11 seconds. A prolongation of 2 seconds is considered as abnormal. Values more than 14 seconds indicate impending hemorrhage. The PT is prolonged if any of the concerned factors are deficient. The present techniques express the prothrombin level as a ratio as INR (Internationalized ratio).

**Liver dysfunction** of acute onset will be reflected as prolonged prothrombin time. Out of 13 clotting factors, 11 are synthesized by the liver. Their synthesis is dependent on availability of vitamin K and normal hepatocellular function.

Prolonged PT may be the initial supportive laboratory parameter to diagnose an acute liver disease. Persistent and progressing prolonged PT is suggestive of fulminant liver failure.

PT measurements are useful to differentiate cholestasis and severe hepatocellular disease. When prolonged PT result is obtained; give vitamin K by intramuscular injection and after 4 hours recheck PT. If the PT becomes normal after vitamin K injection (which is needed for post-translational modification of prothrombin) the diagnosis of cholestasis can be made. If the PT is prolonged, the possibility is severe hepatocellular disease.

**Fibrinolysis**

Unwanted fibrin clots are continuously dissolved in vivo by plasmin, a serine protease. Its inactive precursor is plasminogen (90 kD). It is cleaved into two parts to produce the active plasmin. Plasmin, in turn, is inactivated by alpha-2-antiplasmin.

**Tissue plasminogen activator** (TPA) is a serine protease present in vascular endothelium. TPA is released during injury and then binds to fibrin clots. Then TPA cleaves plasminogen to generate plasmin, which dissolves the clots.

**Urokinase** is another activator of plasminogen. Urokinase is so named because it was first isolated from urine. Urokinase is produced by macrophages, monocytes and fibroblasts. **Streptokinase**, isolated from streptococci is another fibrinolytic agent.

**Clinical significance**

Thrombosis in coronary artery is the major cause of myocardial infarction (heart attack). If TPA, urokinase or streptokinase is injected intravenously in the early phase of thrombosis, the clot may be dissolved and recovery of patient is possible.

**ABNORMALITIES IN COAGULATION**

**Hemophilia A (Classical Hemophilia)**

This is an inherited **X-linked** recessive disease affecting males and transmitted by females. Male children of hemophilia patients are not affected; but female children will be carriers, who transmit the disease to their male offspring (Fig. 28.5). This is due to the deficiency of factor VIII (anti-hemophilic globulin) (AHG). It is the commonest of the inherited coagulation defects.
There will be prolongation of clotting time. Hence, even trivial wounds such as tooth extraction will cause excessive loss of blood. Patients are prone to internal bleeding into joints and intestinal tract.

Until recently the treatment consisted of administration of AHG, prepared from pooled sera every three months. Since this was not generally available, the usual treatment was to transfuse blood periodically, which may lead to eventual iron overload, hemochromatosis (Chapter 35). Several hemophilia patients, receiving repeated transfusions became innocent victims of AIDS. Pure AHG is now being produced by recombinant technology and is the treatment of choice.

**Hemophilia B or Christmas Disease**

It is due to factor IX deficiency. The Christmas disease is named after the first patient reported with this disease. Similar deficiencies of factors X and XI are also reported. In these diseases, the manifestations will be similar to classical hemophilia.

**Other Disorders**

Acquired hypofibrinogenemia or afibrinogenemia may occur as a complication of premature separation of placenta or abruptio placenta. Proteolytic thromboplastic substances may enter from placenta to maternal circulation which sets off the clotting cascade (disseminated intravascular coagulation or DIC). But the clots are usually degraded immediately by plasminolysis. Continuation of this process leads to removal of all available prothrombin and fibrinogen molecules leading to profuse postpartum hemorrhage.

In some cases of carcinoma of pancreas, trypsin is released into circulation leading to intravascular coagulation. This may be manifested as fleeting thrombophlebitis. Trousseau diagnosed his own fatal disease as cancer of pancreas when he developed thrombophlebitis. The combination of carcinoma of pancreas, migratory thrombophlebitis and consumption coagulopathy is termed as Trousseau’s triad.

**Anticoagulants**

They are mainly two types: 1. Acting in vitro to prevent coagulation of collected blood, and 2. Acting in vivo to prevent and regulate coagulation.

The first group of anticoagulant removes calcium which is essential for several steps on clotting. Oxalates, citrate and EDTA belong to this group.

Heparin and antithrombin III are the major in vivo anticoagulants. The heparin-antithrombin complex exerts an inhibitory effect on the serine protease which activates the clotting factors. Alpha-2 macroglobulin has anticoagulant activity.

Heparin is also used as an anticoagulant for in vitro system, e.g. in dialysis and in thrombo-embolic diseases. It is also used in the treatment of intravascular thrombosis. Since vitamin K is essential for coagulation, antagonists to vitamin K are used as anticoagulants, especially for therapeutic purposes, e.g. Dicoumarol and Warfarin (see Chapter 33, under Vitamin K).
Hydrogen ions (H⁺) are present in all body compartments. Maintenance of appropriate concentration of hydrogen ion (H⁺) is critical to normal cellular function. The acid-base balance or pH of the body fluids is maintained by a closely regulated mechanism. This involves the body buffers, the respiratory system and the kidney. Some common definitions are given in Box 29.1. Functions of hydrogen ions include:

1. The gradient of H⁺ concentration between inner and outer mitochondrial membrane acts as the driving force for oxidative phosphorylation.
2. The surface charge and physical configuration of proteins are affected by changes in hydrogen ion concentration.

### ACIDS AND BASES

**Definition**

The electrolyte theory of dissociation was proposed by Arrhenius (Nobel Prize, 1903). According to the definition proposed by Bronsted, acids are substances that are capable of donating protons and bases are those that accept protons. Acids are proton donors and bases are proton acceptors. A few examples are shown below.

<table>
<thead>
<tr>
<th>Acids</th>
<th>Bases</th>
</tr>
</thead>
<tbody>
<tr>

<td>H⁺ + A⁻</td>
</tr>
<tr>
<td>HCl</td>
<td>H⁺ + Cl⁻</td>
</tr>
<tr>
<td>H₂CO₃</td>
<td>H⁺ + HCO₃⁻</td>
</tr>
</tbody>
</table>

#### Weak and Strong Acids

i. The extent of dissociation decides whether they are strong acids or weak acids. Strong acids dissociate completely in solution, while weak acids ionize incompletely, for example,

- HCl → H⁺ + Cl⁻ (Complete)
- H₂CO₃ ↔ H⁺ + HCO₃⁻ (Partial)

### Acid-Base Balance and pH

<td>1</td>
<td></td>
<td>Strong alkali</td>
</tr>
</tbody>
</table>
In a solution of HCl, almost all the molecules dissociate and exist as H+ and Cl– ions. Hence the concentration of H+ is very high and it is a strong acid.

But in the case of a weak acid (e.g. acetic acid), it will ionize only partially. So, the number of acid molecules existing in the ionized state is much less, may be only 50%.

The dissociation constant (Ka) of an acid is given by the formula

\[ [H^+] [A^-] \]

\[ Ka = \frac{[H^+][A^-]}{[HA]} \]

where Ka is the dissociation constant.

To make it easier, Sorensen expressed the H+ concentration as the negative of the logarithm (logarithm to the base 10) of hydrogen ion concentration, and is designated as the pH. Therefore,

\[ pH = -\log[H^+] = \log[H^+] \]

Thus the pH value is inversely proportional to the acidity. Lower the pH, higher the acidity or hydrogen ion concentration while higher the pH, the acidity is lower (Table 29.1).

At a pH of 1, the hydrogen ion concentration is 10 times that of a solution with a pH 2 and 100 times that of a solution with a pH of 3 and so on. The pH 7 indicates the neutral pH, when the hydrogen ion concentration is 100 nanomoles/liter. The pH meter is described in Chapter 48.

### The Effect of Salt upon the Dissociation

i. The relationship between pH, pKa, concentration of acid and conjugate base (or salt) is expressed by the Henderson-Hasselbalch equation,

\[ pH = pKa + \log \frac{[base]}{[acid]} \] or \[ pH = pKa + \log \frac{[salt]}{[acid]} \]

When [base] = [acid]; then pH = pKa

ii. Therefore, when the concentrations of base and acid are the same, then pH is equal to pKa. Thus, when the acid is half ionized, pH and pKa have the same values.

### BUFFERS

#### 1. Definition

Buffers are solutions which can resist changes in pH when acid or alkali is added.

---

---

---
2. Composition of a Buffer
Buffers are of two types:

a. Mixtures of weak acids with their salt with a strong base or
b. Mixtures of weak bases with their salt with a strong acid. A few examples are given below:
   i. $\text{H}_2\text{CO}_3/\text{NaHCO}_3$ (Bicarbonate buffer)
      (carbonic acid and sodium bicarbonate)
   ii. $\text{CH}_3\text{COOH}/\text{CH}_3\text{COO}^-\text{Na}$ (Acetate buffer)
       (acetic acid and sodium acetate)
   iii. $\text{Na}_2\text{HPO}_4/\text{NaH}_2\text{PO}_4$ (Phosphate buffer)

3. Factors Affecting pH of a Buffer
The pH of a buffer solution is determined by two factors:

a. The value of pK: The lower the value of pK, the lower is the pH of the solution.

b. The ratio of salt to acid concentrations: Actual concentrations of salt and acid in a buffer solution may be varying widely, with no change in pH, so long as the ratio of the concentrations remains the same.

4. Factors Affecting Buffer Capacity
   i. On the other hand, the buffer capacity is determined by the actual concentrations of salt and acid present, as well as by their ratio.
   ii. Buffering capacity is the number of grams of strong acid or alkali which is necessary for a change in pH of one unit of one liter of buffer solution.
   iii. The buffering capacity of a buffer is defined as the ability of the buffer to resist changes in pH when an acid or base is added.

5. How do Buffers Act?
   i. Buffer solutions consist of mixtures of a weak acid or base and its salt.
   ii. To take an example, when hydrochloric acid is added to the acetate buffer, the salt reacts with the acid forming the weak acid, acetic acid and its salt. Similarly when a base is added, the acid reacts with it forming salt and water. Thus changes in the pH are minimized.

   \[
   \text{CH}_3\text{–COOH} + \text{NaOH} \rightarrow \text{CH}_3\text{–COONa} + \text{H}_2\text{O} \\
   \text{CH}_3\text{–COONa} + \text{HCl} \rightarrow \text{CH}_3\text{–COOH} + \text{NaCl}
   \]

   iii. The buffer capacity is determined by the absolute concentration of the salt and acid.

6. Application of the Equation
   i. The pH of a buffer on addition of a known quantity of acid and alkali can, therefore, be predicted by the equation.
   ii. Moreover, the concentration of salt or acid can be found out by measuring the pH.
   iii. The Henderson-Hasselbalch’s equation, therefore, has great practical application in clinical practice in assessing the acid-base status, and predicting the limits of the compensation of body buffers.

7. Effective Range of a Buffer
A buffer is most effective when the concentrations of salt and acid are equal or when pH = pKa. The effective range of a buffer is 1 pH unit higher or lower than pKa. Since the pKa values of most of the acids produced in the body are well below the physiological pH, they immediately ionize and add H⁺ to the medium. This would necessitate effective buffering. Phosphate buffer is effective at a wide range, because it has 3 pKa values.

ACID-BASE BALANCE
Normal pH
The pH of plasma is 7.4 (average hydrogen ion concentration of 40 nanomoles/liter). In normal life, the variation of plasma pH is very small. The pH of plasma is maintained within a narrow range of 7.38 to 7.42. The pH of the interstitial fluid is generally 0.5 units below that of the plasma.

Acidosis
If the pH is below 7.38, it is called acidosis. Life is threatened when the pH is lowered below 7.25. Acidosis leads to CNS depression and coma. Death occurs when pH is below 7.0.

Alkalosis
When the pH is more than 7.42, it is alkalosis. It is very dangerous if pH is increased above 7.55.
Alkalosis induces neuromuscular hyperexcitability and tetany. Death occurs when the pH is above 7.6.

Volatile and Fixed Acids

i. During the normal metabolism, the acids produced may be volatile acids like carbonic acid or nonvolatile (fixed) acids like lactate, keto acids, sulfuric acid and phosphoric acid.

ii. The metabolism produces nearly 20,000 milli equivalents (mEq) of carbonic acid and 60-80 mEq of fixed acids per day.

iii. The lactate and keto acids are produced in relatively fixed amounts by normal metabolic activity, e.g. 1 mol of glucose produces 2 mols of lactic acid.

iv. The dietary protein content decides the amount of sulfuric and phosphoric acids. The sulfoproteins yield sulfuric acid and phosphoproteins and nucleoproteins produce phosphoric acid. On an average about 3 g of phosphoric acid and about 3 g sulfuric acid are produced per day.

v. The carbonic acid, being volatile, is eliminated as CO₂ by the lungs. The fixed acids are buffered and later on the H⁺ are excreted by the kidney. The mechanisms of regulation of pH are inter-related (Box 29.2).

1. BUFFERS OF THE BODY FLUIDS

Buffers are the first line of defense against acid load. These buffer systems are enumerated in Table 29.2. The buffers are effective as long as the acid load is not excessive, and the alkali reserve is not exhausted. Once the base is utilized in this reaction, it is to be replenished to meet further challenge.

1-A. Bicarbonate Buffer System

i. The most important buffer system in the plasma is the bicarbonate-carbonic acid system (NaHCO₃/H₂CO₃). It accounts for 65% of buffering capacity in plasma and 40% of buffering action in the whole body.

ii. The base constituent, bicarbonate (HCO₃⁻), is regulated by the kidney (metabolic component).

iii. While the acid part, carbonic acid (H₂CO₃), is under respiratory regulation (respiratory component).

iv. The normal bicarbonate level of plasma is 24 mmol/liter. The normal pCO₂ of arterial blood is 40 mm of Hg. The normal carbonic acid concentration in blood is 1.2 mmol/L. The pKa for carbonic acid is 6.1. Substituting these values in the Henderson-Hasselbalch’s equation,

\[
pH = pKa + \log \frac{[HCO_3^-]}{[H_2CO_3]}
\]

\[
7.4 = 6.1 + \log \frac{24}{1.2} = 6.1 + \log 20 = 6.1 + 1.3
\]

v. Hence, the ratio of HCO₃⁻ to H₂CO₃ at pH 7.4 is 20 under normal conditions. This is much higher than the theoretical value of 1 which ensures maximum effectiveness.

vi. The bicarbonate carbonic acid buffer system is the most important for the following reasons:

a. Presence of bicarbonate in relatively high concentrations.

b. The components are under physiological control, CO₂ by lungs and bicarbonate by kidneys.
1-B. Alkali Reserve

Bicarbonate represents the alkali reserve and it has to be sufficiently high to meet the acid load. If it was too low to give a ratio of 1, all the \( \text{HCO}_3^- \) would have been exhausted within a very short time; and buffering will not be effective. So, under physiological circumstances, the ratio of 20 (a high alkali reserve) ensures high buffering efficiency against acids.

1-C. Phosphate Buffer System

It is mainly an intracellular buffer. Its concentration in plasma is very low. The pKa value is 6.8. So applying the equation,

\[
\text{pH} (7.4) = \text{pKa} (6.8) + \log \frac{[\text{salt}]}{[\text{acid}]}
\]

or \( 0.6 = \log \frac{[\text{salt}]}{[\text{acid}]} \)

Antilog of 0.6 = 4; hence the ratio is 4. This is found to be true under physiological condition.

The phosphate buffer system is found to be effective at a wide pH range, because it has more than one ionizable group and the pKa values are different for both.

\[
\begin{align*}
\text{pKa} &= 1.96 \\
\text{H}_3\text{PO}_4 &\rightarrow \text{H}^+ + \text{H}_2\text{PO}_4^- \\
\text{pKa} &= 6.8 \\
\text{H}_2\text{PO}_4^- &\rightarrow \text{H}^+ + \text{HPO}_4^{2-} (\text{Na}_2\text{HPO}_4/\text{NaH}_2\text{PO}_4) \\
\text{pKa} &= 12.4 \\
\text{HPO}_4^{2-} &\rightarrow \text{H}^+ + \text{PO}_4^{3-}
\end{align*}
\]

In the body, \( \text{Na}_2\text{HPO}_4/\text{NaH}_2\text{PO}_4 \) is an effective buffer system, because its pKa value is nearest to physiological pH.

1-D. Protein Buffer System

Buffering capacity of protein depends on the pKa value of ionizable side chains. The most effective group is histidine imidazole group with a pKa value of 6.1. The role of the hemoglobin buffer is considered along with the respiratory regulation of pH.

1-E. Relative Capacity of Buffer Systems

In the body, 52% buffer activity is in tissue cells and 6% in RBCs. Rest 43% is by extracellular buffers. In plasma and extracellular space, about 40% buffering action is by bicarbonate system; 1% by proteins and 1% by phosphate buffer system (Fig. 29.1).

1-F. Buffers Act Quickly, But Not Permanently

Buffers can respond immediately to addition of acid or base, but they do not serve to eliminate the acid from the body. They are also unable to replenish the alkali reserve of the body. For the final elimination of acids, the respiratory and renal regulations are very essential.

2. RESPIRATORY REGULATION OF pH

2-A. The Second Line of Defense

i. This is achieved by changing the pCO\(_2\) (or carbonic acid, the denominator in the equation). The CO\(_2\) diffuses from the cells into the extracellular fluid and reaches the lungs through the blood.

ii. The rate of respiration (rate of elimination of CO\(_2\)) is controlled by the chemoreceptors in the respiratory center which are sensitive to changes in the pH of blood.

iii. When there is a fall in pH of plasma (acidosis), the respiratory rate is stimulated resulting in hyperventilation. This would eliminate more CO\(_2\), thus lowering the H\(_2\)CO\(_3\) level (Box 29.3).

iv. However, this cannot continue for long. The respiratory system responds to any change in pH immediately, but it cannot proceed to completion.

2-B. Action of Hemoglobin

i. The hemoglobin serves to transport the CO\(_2\) formed in the tissues, with minimum change in pH. (See isohydric transport, Chapter 22).

ii. Side by side, it serves to generate bicarbonate or alkali reserve by the activity of the carbonic anhydrase system (Chapter 22).
The activity of the carbonic anhydrase (also called carbonate dehydratase) increases in acidosis and decreases with decrease in H+ concentration.

3. RENAL REGULATION OF pH

An important function of the kidney is to regulate the pH of the extracellular fluid. Normal urine has a pH around 6; this pH is lower than that of extracellular fluid (pH = 7.4). This is called acidification of urine. The pH of the urine may vary from as low as 4.5 to as high as 9.8, depending on the amount of acid excreted. The major renal mechanisms for regulation of pH are:

A. Excretion of H+ (Fig. 29.2)

B. Reabsorption of bicarbonate (recovery of bicarbonate) (Fig. 29.3)

C. Excretion of titratable acid (net acid excretion) (Fig. 29.4)

D. Excretion of NH₄⁺ (ammonium ions) (Fig. 29.5).

3-A. Excretion of H⁺; Generation of Bicarbonate

i. This process occurs in the proximal convoluted tubules (Fig. 29.2).

ii. The CO₂ combines with water to form carbonic acid, with the help of carbonic anhydrase. The H₂CO₃ then ionizes to H⁺ and bicarbonate.

iii. The hydrogen ions are secreted into the tubular lumen; in exchange for Na⁺ reabsorbed. These Na⁺ ions along with HCO₃⁻ will be reabsorbed into the blood.

iv. There is net excretion of hydrogen ions, and net generation of bicarbonate. So this mechanism serves to increase the alkali reserve.
3-B. Reabsorption of Bicarbonate

i. This is mainly a mechanism to conserve base. There is no net excretion of H⁺ (Fig. 29.3).

ii. The cells of the PCT have a sodium hydrogen exchanger. When Na⁺ enters the cell, hydrogen ions from the cell are secreted into the luminal fluid. The hydrogen ions are generated within the cell by the action of carbonic anhydrase.

iii. The hydrogen ions secreted into the luminal fluid is required for the reabsorption of filtered bicarbonate.

iv. Bicarbonate is filtered by the glomerulus. This is completely reabsorbed by the proximal convoluted tubule, so that the urine is normally bicarbonate free.

v. The bicarbonate combines with H⁺ in tubular fluid to form carbonic acid. It dissociates into water and CO₂. The CO₂ diffuses into the cell, which again combines with water to form carbonic acid.

vi. In the cell, it again ionizes to H⁺ that is secreted into lumen in exchange for Na⁺. The HCO₃⁻ is reabsorbed into plasma along with Na⁺.

vii. Here, there is no net excretion of H⁺ or generation of new bicarbonate. The net effect of these processes is the reabsorption of filtered bicarbonate which is mediated by the Sodium-Hydrogen exchanger. But this mechanism prevents the loss of bicarbonate through urine.

3-C. Excretion of H⁺ as Titratable Acid

i. In the distal convoluted tubules net acid excretion occurs. Hydrogen ions are secreted by the distal tubules and collecting ducts by hydrogen ion-ATPase located in the apical cell membrane. The hydrogen ions are generated in the tubular cell by a reaction catalyzed by carbonic anhydrase. The bicarbonate generated within the cell passes into plasma.

ii. The term titratable acidity of urine refers to the number of milliliters of N/10 NaOH required to titrate 1 liter of urine to pH 7.4. This is a measure of net acid excretion by the kidney.

iii. The major titratable acid present in the urine is sodium acid phosphate. As the tubular fluid passes down the renal tubules more and more H⁺ are secreted into the luminal fluid so that its pH steadily falls. The process starts in the proximal tubules, but continues up to the distal tubules.

iv. Due to the Na⁺ to H⁺ exchange occurring at the renal tubular cell border, the Na₂HPO₄ (basic phosphate) is converted to NaH₂PO₄ (acid phosphate) (Fig. 29.4). As a result, the pH of tubular fluid falls.

v. The acid and basic phosphate pair is considered as the urinary buffer. The maximum limit of acidification is pH 4.5. This process is inhibited by carbonic anhydrase inhibitors like acetazolamide.

3-D. Excretion of Ammonium Ions

i. Predominantly occurs at the distal convoluted tubules. This would help to excrete H⁺ and reabsorb HCO₃⁻ (Fig. 29.5).

ii. This mechanism also helps to trap hydrogen ions in the urine, so that large quantity of acid may be excreted with minor changes in pH. The excretion of ammonia helps in the elimination of hydrogen ions without appreciable change in the pH of the urine.

iii. The Glutaminase present in the tubular cells can hydrolyze glutamine to ammonia and glutamic acid. The NH₃ (ammonia) diffuses into the luminal fluid and combines with H⁺ to form NH₄⁺ (ammonium ion). The glutaminase activity is increased in acidosis. So large quantity of H⁺ ions are excreted as NH₄⁺ in acidosis.

iv. Since it is a positively charged ion, it can accompany negatively charged acid anions; so Na⁺ and K⁺ are conserved (Fig. 29.5).

v. Normally, about 70 mEq/L of acid is excreted daily; but in condition of acidosis, this can rise to 400 mEq/day.
vi. The enhanced activity of glutaminase and increased excretion of $\text{NH}_4^+$ takes about 3-4 days to set in under conditions of acidosis. But once established, it has high capacity to eliminate acid.

vii. Ammonia is estimated in urine, after addition of formaldehyde. The titratable acidity plus the ammonia content will be a measure of acid excreted from the body. Maximum urine acidity reached is 4.4. A summary of buffering of acid load in the body is shown in Table 29.3.

**Box 29.5. Steps to the Clinical Assessment of Acid-Base Disturbances**

1. Assess pH (normal 7.4); pH <7.38 is acidemia and >7.42 is alkalemia
2. Serum bicarbonate level: See Box 29.6.
3. Assess arterial pCO$_2$: See Box 29.6.
4. Check compensatory response: Compensation never overcorrects the pH.
   If pH is <7.4, acidosis is the primary disorder.
   If pH is >7.4, alkalosis is primary.
5. Assess anion gap.
6. Assess the change in serum anion gap/change in bicarbonate.
7. Assess if there is any underlying cause.
8. Reduction in pH reduces the contractility of actin and myosin in muscles.
9. The electrical properties of excitable cells are also affected by changes in pH.

Intracellular buffers are depicted in Figure 29.2. The major tissues involved in cellular buffering are bone and skeletal muscle. The buffering of acid is achieved by the exchange of $\text{H}^+$ that enters into the cells for $\text{Na}^+$ or $\text{K}^+$ ions.

**Relationship of pH with $\text{K}^+$ Ion Balance**

i. When there is increase in $\text{H}^+$ in extracellular fluid (ECF), there may be exchange of $\text{H}^+$ with $\text{K}^+$ from within the cells. Net effect is an apparent increase in ECF potassium level (hyperkalemia).

ii. In general, metabolic acidosis is associated with hyperkalemia and metabolic alkalosis with hypokalemia.

iii. However, in renal tubular acidosis, due to failure to excrete hydrogen ions, potassium is lost in urine; then hypokalemia results.

iv. Sudden hypokalemia may develop during the correction of acidosis. $\text{K}^+$ may go back into the cells, suddenly lowering the plasma $\text{K}^+$. Hence, it is important to maintain the $\text{K}^+$ balance during correction of acidosis.

**Factors Affecting Renal Acid Excretion**

1. Increased filtered load of bicarbonate
2. Decrease in ECF volume
3. Decrease in plasma pH
4. Increase in pCO$_2$ of blood
5. Hypokalemia
6. Aldosterone secretion

**CELLULAR BUFFERS**

Cytoplasmic pH varies from 6.8 to 7.3. Intracellular pH modulates a variety of cell functions:

1. The activity of several enzymes is sensitive to changes in pH.
DISTURBANCES IN ACID-BASE BALANCE

Acidosis is the clinical state, where acids accumulate or bases are lost. A loss of acid or accumulation of base leads to alkalosis. The body cells can tolerate only a narrow range of pH. The extreme ranges of pH are between 7.0 and 7.6, beyond which life is not possible. Box 29.4 shows the conditions in which acid-base parameters are to be checked. Box 29.5 shows the steps to the clinical assessment of acid base status. Box 29.6 summarizes the abnormal findings.

Classification of Acid-Base Disturbances

1. Acidosis (Fall in pH)
   a. Respiratory acidosis: Primary excess of carbonic acid.
   b. Metabolic acidosis: Primary deficit of bicarbonate (See Box 29.6)

2. Alkalosis (Rise in pH)
   a. Respiratory alkalosis: Primary deficit of carbonic acid.
   b. Metabolic alkalosis: Primary excess of bicarbonate (See Box 29.6).

3. Compensatory responses
   Each of the above disturbances will be followed by a secondary compensatory change in the counteracting variable, e.g. a primary change in bicarbonate involves an alteration in pCO₂. Depending on the extent of the compensatory change there are different stages (see Table 29.3). In actual clinical states, patients will have different states of compensation (Box 29.7). The compensatory (adaptive) responses are:
   a. A primary change in bicarbonate involves an alteration in pCO₂. The direction of the change is the same as the primary change and there is an attempt at restoring the ratio to 20 and pH to 7.4.
   b. Adaptive response is always in the same direction as the primary disturbance. Primary decrease in arterial bicarbonate involves a reduction in arterial blood pCO₂ by alveolar hyperventilation.
   c. Similarly, a primary increase in arterial pCO₂ involves an increase in arterial bicarbonate by an increase in bicarbonate reabsorption by the kidney.
   d. The compensatory change will try to restore the pH to normal. However, the compensatory change cannot fully correct a disturbance.

   e. Clinically, acid-base disturbance states may be divided into:
      i. Uncompensated
      ii. Partially compensated
      iii. Fully compensated (Table 29.4).

Box 29.7. Acid-base Disturbances. Expected Renal and Respiratory Compensations

| Metabolic acidosis: | Expect pCO₂ to be reduced by 1 mm Hg for every 1 mmol/L drop in bicarbonate. |
| Metabolic alkalosis: | Expect pCO₂ to be increased by 0.6 mm Hg for every 1 mmol/L rise in bicarbonate. |
| Acute respiratory acidosis: | Expect 1 mmol/L increase in bicarbonate per 10 mm Hg rise in pCO₂. |
| Chronic respiratory acidosis: | Expect 3.5 mmol/L increase in bicarbonate per 10 mm Hg rise in pCO₂. |
| Acute respiratory alkalosis: | Expect 2 mmol/L decrease in bicarbonate per 10 mm Hg fall in pCO₂. |
| Chronic respiratory alkalosis: | Expect 4 mmol/L decrease in bicarbonate per 10 mm Hg fall in pCO₂. |
4. Mixed Responses

i. If the disturbance is pure, it is not difficult to accurately assess the nature of the disturbance (Box 29.7). In mixed disturbances, both HCO$_3^-$ and H$_2$CO$_3$ levels are altered (Fig. 29.6).

ii. The adaptive response always involves a change in the counteracting variable; e.g. a primary change in bicarbonate involves an alteration in pCO$_2$.

iii. Adaptive response is always in the same direction as the primary disturbance.

iv. Depending on the extent of the compensatory change there are different stages. Looking at the parameters, the stage of the compensation can be identified (Table 29.4).

Chemical Pathology of Acid-Base Disturbances

Metabolic Acidosis

i. It is due to a primary deficit in the bicarbonate, resulting from an accumulation of acid or depletion of bicarbonate.

ii. When there is excess acid production, the bicarbonate is used up for buffering. Depending on the cause, the anion gap is altered.

1. Anion Gap

i. The sum of cations and anions in ECF is always equal, so as to maintain the electrical neutrality. Sodium and potassium together account for 95% of the cations whereas chloride and bicarbonate account for only 86% of the anions (Fig. 29.7). Only these electrolytes are commonly measured.

ii. Hence there is always a difference between the measured cations and the anions. The

Fig. 29.6. Bicarbonate diagram

Fig. 29.7. Gamblegram showing cations on the left and anions on the right side. Such bar diagrams were first depicted by Gamble, hence these are called Gamble grams.
unmeasured anions constitute the anion gap. This is due to the presence of protein anions, sulphate, phosphate and organic acids.

iii. The anion gap is calculated as the difference between \((Na^+ + K^+)\) and \((HCO_3^- + Cl^-)\). Normally this is about 12 mmol/liter.

2-A. High Anion Gap Metabolic Acidosis (HAGMA)

i. A value between 15 and 20 is accepted as reliable index of accumulation of acid anions in metabolic acidosis (HAGMA) (Table 29.5). However, the gap is artificially increased when the cations are decreased (hypokalemia, hypocalcemia, hypomagnesemia). It is artificially altered when there is hypoalbuminemia (decrease in negatively charged protein), hypergammaglobulinemia (increase in positively charged protein) and rarely when other cations are increased (hyperkalemia, hypercalcemia, hypermagnesemia).

ii. Renal failure: The excretion of \(H^+\) as well as generation of bicarbonate are both deficient. The anion gap increases due to accumulation of other buffer anions.

iii. Diabetic ketoacidosis (Chapter 11).

iv. Lactic acidosis: Normal lactic acid content in plasma is less than 2 mmol/L. It is increased in tissue hypoxia, circulatory failure, and intake of biguanides (Box 29.8). Lactic acidosis causes a raised anion gap (Box 29.8), whereas diarrhea causes a normal anion gap acidosis (Table 29.6).

Suppose 5 mmol/L lactic acid has entered in blood; this is buffered by bicarbonate, resulting in 5 mmol/L of sodium lactate and 5 mmol/L of carbonic acid. The carbonic acid is dissociated into water and carbon dioxide, which is removed by lung ventilation. The result is lowering of bicarbonate by 5 mmol and presence of 5 mmol of unmeasured anion (lactate), with no changes in sodium or chloride. So, anion gap is increased. In contrast, diarrhea results in the loss of bicarbonate. NaCl is reabsorbed more from kidney tubules to maintain the extracellular volume, resulting in the increase in serum chloride. This chloride compensates for the fall in bicarbonate. So, diarrhea results in hyperchloremic, normal anion gap, metabolic acidosis.

2-B. Normal Anion Gap Metabolic Acidosis (NAGMA)

When there is a loss of both anions and cations, the anion gap is normal, but acidosis may prevail. Causes are described in Table 29.6.
i. Diarrhea: Loss of intestinal secretions lead to acidosis. Bicarbonate, sodium and potassium are lost.

ii. Hyperchloremic acidosis may occur in renal tubular acidosis, acetazolamide (carbonic anhydrase inhibitor) therapy, and ureteric transplantation into large gut (done for bladder carcinoma).

a. Renal tubular acidosis may be due to failure to excrete acid or reabsorb bicarbonate.

b. Chloride is elevated since electrical neutrality has to be maintained.

c. In ureteric transplantation, the chloride ions are reabsorbed in exchange for bicarbonate ions lost, leading to hyperchloremic acidosis.

d. Acetazolamide therapy results in metabolic acidosis because HCO₃⁻ generation and H⁺ secretion are affected.

iii. Urine anion gap (UAG) is useful to estimate the ammonium excretion. It is calculated as

\[ \text{UAG} = \text{UNa} + \text{UK} – \text{UCl} \]

The normal value is –20 to –50 mmol/L. In metabolic acidosis, the NH₄Cl excretion increases, and UAG becomes –75 or more. But in RTA, ammonium excretion is defective, and UAG has positive value. Causes for RTA are enumerated in Box 29.9.

3. Decreased Anion Gap is Seen in

Hypoalbuminemia
Multiple myeloma (paraproteinemia)
Bromide intoxication
Hypercalcemia

4. Osmolal Gap
This is the difference between the measured plasma osmolality and the calculated osmolality, which may be calculated as

\[ 2 \times [\text{Na}] + [\text{glucose}] + [\text{urea}] \]

The normal osmolal gap is <10 mOsm. A high osmolal gap (> 25) implies the presence of unmeasured osmoles such as alcohol, methanol, ethylene glycol, etc. Acute poisoning should be considered in patients with a raised anion gap metabolic acidosis and an increased plasma osmolal gap. Poisoning with methanol and ethylene glycol should be considered. They are metabolized to formic acid and oxalic acids correspondingly. Methanol will produce blindness. Ethylene glycol will lead to oxalate crystalluria and renal failure.

|                                           | Marfan’s syndrome                                |

| Type IV                                    | Impaired aldosterone secretion                   |

| iii. Urine anion gap (UAG) is useful to estimate the ammonium excretion. It is calculated as UAG = UNa + UK – UCl |
|                                                                 | The normal value is –20 to –50 mmol/L. In metabolic acidosis, the NH₄Cl excretion increases, and UAG becomes –75 or more. But in RTA, ammonium excretion is defective, and UAG has positive value. Causes for RTA are enumerated in Box 29.9. |

### 3. Decreased Anion Gap is Seen in

Hypoalbuminemia
Multiple myeloma (paraproteinemia)
Bromide intoxication
Hypercalcemia

### 4. Osmolal Gap
This is the difference between the measured plasma osmolality and the calculated osmolality, which may be calculated as

\[ 2 \times [\text{Na}] + [\text{glucose}] + [\text{urea}] \]

The normal osmolal gap is <10 mOsm. A high osmolal gap (> 25) implies the presence of unmeasured osmoles such as alcohol, methanol, ethylene glycol, etc. Acute poisoning should be considered in patients with a raised anion gap metabolic acidosis and an increased plasma osmolal gap. Poisoning with methanol and ethylene glycol should be considered. They are metabolized to formic acid and oxalic acids correspondingly. Methanol will produce blindness. Ethylene glycol will lead to oxalate crystalluria and renal failure.
5. Compensated Metabolic Acidosis

i. Decrease in pH in metabolic acidosis stimulates the respiratory compensatory mechanism and produces hyperventilation—Kussmaul respiration to eliminate carbon dioxide leading to hypocapnia (Hypocarbia). The pCO₂ falls and this would attempt to restore the ratio towards 20 (partial compensation).

ii. Renal compensation: Increased excretion of acid and conservation of base occurs. Na-H exchange, NH₄⁺ excretion and bicarbonate reabsorption are increased. As much as 500 mmol acid is excreted per day. The reabsorption of more bicarbonate also helps to restore the ratio to 20.

iii. Renal compensation sets in within 2 to 4 days. If the ratio is restored to 20, the condition is said to be fully compensated. But unless the cause is also corrected, restoration of normalcy cannot occur.

iv. Associated hyperkalemia is commonly seen due to a redistribution of K⁺ and H⁺. The intracellular K⁺ comes out in exchange for H⁺ moving into the cells. Hence care should be taken while correcting acidosis which may lead to sudden hypokalemia. This is more likely to happen in treating diabetic ketoacidosis by giving glucose and insulin together.

v. Changes in albumin level or changes in the negative charge on the protein molecules can give altered Anion Gap (AG) values. Therefore when pH increases the AG may show an increase and in hypoalbuminemia AG will show a decrease. In order to overcome these difficulties a new term “Strong ion gap” (SIG) has been introduced, which is the corrected AG.

Clinical Features of Metabolic Acidosis
The respiratory response to metabolic acidosis is to hyperventilate. So there is marked increase in respiratory rate and depth of respiration; this is called as Kussmaul respiration. The acidosis is said to be dangerous when pH is <7.2 and serum bicarbonate is <10 mmol/L. In such conditions, there is depressed myocardial contractility.
Treatment of Metabolic Acidosis
Treatment is to stop the production of acid. In ketoacidosis, treatment is to give intravenous fluids, insulin and potassium replacement. Oxygen is given in patient with lactic acidosis. In all cases, potassium abnormalities should be carefully looked into and treated.

**Bicarbonate Requirement:** The amount of bicarbonate required to treat acidosis is calculated from the base deficit. In cases of acidosis, \( \text{mEq of base needed} = \text{body wt in Kg} \times 0.2 - \text{base excess in mEq/L} \).

Metabolic Alkalosis

i. **Primary excess of bicarbonate** is the characteristic feature. Alkalosis occurs when a) excess base is added, b) base excretion is defective or c) acid is lost. All these will lead to an excess of bicarbonate, so that the ratio becomes more than 20. Important causes and findings are given in Table 29.7. This results either from the loss of acid or from the gain in base.

ii. Loss of acid may result from severe vomiting or gastric aspiration leading to loss of chloride and acid. Therefore, *hypochloremic* alkalosis results.

iii. **Hyperaldosteronism** causes retention of sodium and loss of potassium.

iv. **Hypokalemia** is closely related to metabolic alkalosis. In alkalosis, there is an attempt to conserve hydrogen ions by kidney in exchange for \( K^+ \). This potassium loss can lead to hypokalemia.

Subclassification of metabolic alkalosis

i. In **Chloride responsive** conditions, urinary chloride is less than 10 mmol/L. It is seen in prolonged vomiting, nasogastric aspiration or administration of diuretics.

ii. In **Chloride resistant** condition, urine chloride is greater than 10 mmol/L; it is seen in hypertension, hyperaldosteronism, severe potassium depletion and *Cushing's syndrome.*

iii. Due to the exogenous base which is often iatrogenic.

**Clinical Features of Metabolic Alkalosis**
The respiratory center is depressed by the high pH leading to *hypoventilation*. This would result in accumulation of \( \text{CO}_2 \) in an attempt to lower the \( \text{HCO}_3^-/\text{H}_2\text{CO}_3 \) ratio. However, the compensation is limited by the hypoxic stimulation of respiratory center, so that the increase in \( \text{PaCO}_2 \) is not above 55 mm Hg (Box 29.10).

The renal mechanism is more effective which conserves \( \text{H}^+ \) and excretes more \( \text{HCO}_3^- \). However, complete correction of alkalosis will be effective only if potassium is administered and the cause is removed (Table 29.8).

Increased neuromuscular activity is seen when pH is above 7.55. Tetany results even in the presence of normal serum calcium.

**Respiratory Acidosis**

i. **A primary excess of carbonic acid** is the cardinal feature. It is due to \( \text{CO}_2 \) retention as a result of hypoventilation. The ratio of bicarbonate to carbonic acid will be less than 20. Depending on whether the condition is of acute or chronic onset, the extent of compensation varies.

ii. **Acute** respiratory acidosis may result from *bronchopneumonia* or status asthmaticus.

iii. Depression of respiratory center due to overdose of sedatives or *narcotics* may also lead to hypercapnia.

iv. **Chronic** obstructive lung disease will lead to chronic respiratory acidosis, where the fall in pH will be minimal. The findings in chronic and acute respiratory acidosis are summarized in Table 29.8.

Excess carbonic acid is buffered by hemoglobin and protein buffer systems. This could cause a slight

| Metabolic acidosis, \( \text{pCO}_2 \) | 15 mm of Hg |
| Metabolic alkalosis, \( \text{pCO}_2 \) | 50 mm of Hg |
| Respiratory acidosis, bicarbonate | 32 mmol/L |
| Respiratory alkalosis, bicarbonate | 15 mmol/L |

**Clinical Features of Respiratory Acidosis**

\( N \) = normal; ↓ = decreased; ↑ = increased
rise in bicarbonate. Kidneys respond by conserving base (HCO$_3^-$) and excreting H$^+$ as NH$_4^+$. Chronic cases will be well compensated unlike acute cases. In respiratory acidosis, bicarbonate level is increased (not decreased).

Clinically, there is decreased respiratory rate, hypotension and coma. Hypercapnia may lead to peripheral vasodilation, tachycardia and tremors. The findings in chronic and acute respiratory acidosis are summarized in Table 29.8. The renal compensation occurs, generating more bicarbonate and excreting more H$^+$.

Respiratory Alkalosis
i. A primary deficit of carbonic acid is described as the respiratory alkalosis.

B. Metabolic Acidosis
i. High anion gap
   - Diabetic ketoacidosis
   - Lactic acidosis
   - Renal failure

ii. Normal anion gap
   - Renal tubular acidosis
   - (hyperchloremic)
   - CA inhibitors
   - Diarrhea
   - Addison's disease

B. Metabolic Alkalosis
- Severe vomiting
- Cushing syndrome
- Milk alkali syndrome
- Diuretic therapy (potassium loss)

Hyperventilation will result in washing out of CO$_2$. So, bicarbonate : carbonic acid ratio is more than 20.

ii. Causes are hysterical hyperventilation, raised intracranial pressure and brain stem injury.

iii. Early stage of salicylate poisoning causes respiratory alkalosis due to stimulation of respiratory center. But later, it ends up in metabolic acidosis due to accumulation of organic acids, lactic and keto acids.

iv. Other causes include lung diseases (pneumonia, pulmonary embolism).

v. The pCO$_2$ is low, pH is high and bicarbonate level increases. But bicarbonate level falls, when compensation occurs. Compensation occurs immediately in acute stages. In prolonged chronic cases renal compensation sets in. Bicarbonate level is reduced by decreasing the reclamation of filtered bicarbonate.

vi. Clinically, hyperventilation, muscle cramps, tingling and paraesthesia are seen. Alkaline pH will favor increased binding of calcium to proteins, resulting in a decreased ionized calcium, leading to paraesthesia. Causes of acidosis and alkalosis are enumerated in Box 29.11.

Assessment of Acid–Base Parameters
i. The assessment of acid-base status is usually done by the arterial blood gas (ABG) analyzer, which
measures pH, pCO₂, and pO₂ directly, by means of electrodes. Arterial blood is used to measure the acid-base parameters.

ii. In the absence of a blood gas analyzer, venous blood may be collected under paraffin (to eliminate contact with air). Bicarbonate is estimated by titration to pH 7.4. From the values of Na⁺, K⁺, Cl⁻, and HCO₃⁻, the anion gap is calculated. Most of the critical care analyzers estimate the blood gas, electrolytes, and calculate the anion gap.

For clinical assessment, instead of Henderson-Hasselbalch equation, a modified version, **Henderson equation** is used.

\[
H^+ (\text{nmol/L}) = \frac{24 \times \text{pCO}_2 \text{ in mm of Hg}}{\text{HCO}_3^-}
\]

24 in the equation is a constant and takes into account pK and gas solubility. From the H⁺ concentration thus obtained, the pH may be calculated. A change in pH unit by 0.01 represents a change in H⁺ by 1 nanomol/L, from the normal value of 40 nanomol/L.

For example,

\[
\begin{align*}
H^+ &= 50 \text{ nanomol/L} = 7.4 - (10 \times .01) = 7.3 \\
H^+ &= 30 \text{ nanomol/L} = 7.4 + (10 \times .01) = 7.5
\end{align*}
\]

**Arterial Oxygen Saturation (SaO₂)**

It is measured by pulse oximeter. SaO₂ assesses oxygenation, but will give no information about the respiratory ventilation. A small drop in SaO₂ represents a large drop in pO₂. Increased ventilation will lower the pCO₂, leading to respiratory alkalosis. Decreased ventilation will raise the pCO₂ and lead to a respiratory acidosis.

**Normal Serum Electrolyte Values**

Please see Box 29.12. Students should always remember these values. Upper and lower limits are shown in Box 29.10. The causes of acid-base disturbances are shown in Box 29.11. Some examples of abnormalities are given in Table 29.9.

**Related Topics**

Renal mechanisms and renal function tests are described in Chapter 27. Metabolisms of sodium, potassium, and chloride are described in Chapter 30.
The reader will be able to answer questions on the following topics:
1. Intake and output of water
2. Osmolality of extracellular fluid
3. Electrolyte composition of body fluids
4. Regulation of sodium and water balance
5. Renin-Angiotensin system
6. Isotonic/hypotonic/hypertonic contraction, ECF
7. Isotonic/hypotonic/hypertonic expansion, ECF
8. Sodium metabolism
9. Potassium metabolism
10. Chloride metabolism

The maintenance of extracellular fluid volume and pH are closely interrelated. The body water compartments are shown in Box 30.1. Body is composed of about 60-70% water. Distribution of water in different body water compartments depends on the solute content of each compartment. Osmolality of the intra- and extracellular fluid is the same, but there is marked difference in the solute content.

**Intake and Output of Water**
During oxidation of food stuffs, 1g carbohydrate produces 0.6 ml of water, 1g protein releases 0.4 ml water and 1 g fat generates 1.1 ml of water. Intake of 1000 kcal produces 125 ml water (Table 30.1).

**Box 30.1. The Body Water Compartments**
- Total body water (42 L) (60% of body weight)
  - Intracellular (28 L) (40% body wt)
  - Extracellular (14 L) (20% body wt)
- Intravascular (4%) (2.8 L)
- Extravascular (16%) (11.2 L)

</tbody>
</table>

The major factors controlling the intake are thirst and the rate of metabolism.

The thirst center is stimulated by an increase in the osmolality of blood, leading to increased intake.

The renal function is the major factor controlling the rate of output. The rate of loss through skin is influenced by the weather, the loss being more in hot climate (perspiration) and less in cold climate. Loss of water through skin is increased to 13% for each degree rise in centigrade in body temperature during fever.

Osmolality of Extracellular Fluid

i. Osmolarity means osmotic pressure exerted by the number of moles per liter of solution.

ii. Osmolality is the osmotic pressure exerted by the number of moles per kg of solvent.

iii. Crystalloids and water can easily diffuse across membranes, but an osmotic gradient is provided by the non-diffusible colloidal (protein) particles. The colloid osmotic pressure exerted by proteins is the major factor which maintains the intracellular and intravascular fluid compartments. If this gradient is reduced, the fluid will extravasate and accumulate in the interstitial space leading to edema.

iv. Albumin is mainly responsible in maintaining this osmotic balance (Chapter 28). The composition of each body fluid compartment is shown in Figure 30.1 and Table 30.2).

v. Since osmolality is dependent on the number of solute particles, the major determinant factor is the sodium. Therefore, sodium and water balance are dependent on each other and cannot be considered separately.

vi. The osmolality of plasma varies from 285 to 295 mosm/kg (see Table 30.3). It is maintained by the kidney which excretes either water or solute as the case may be.

vii. Plasma osmolality can be measured directly using the osmometer or indirectly as the concentration of effective osmoles. It may be roughly estimated for clinical purpose by the formula:

\[
\text{Osmolality} = [\text{Na}^+ (280)] + [\text{glucose} (5)] + [\text{Urea} (5)] - 10; \\
\text{all values being calculated in mmol/L. The factor 2 in the above equation is to account for ionization of sodium and negative anions accompanying.}
\]

viii. The difference in measured osmolality and calculated osmolality may increase causing an Osmolar Gap, when abnormal compounds like ethanol, mannitol, neutral and cationic amino acids, etc. are present.

Effective Osmolality

i. It is the term used for those extracellular solutes that determine water movement across the cell membrane. Permeable solutes such as urea and alcohol, enter into the cell and achieve osmotic equilibrium. Although there is increase in osmolality, there is no shift in water.

ii. On the other hand, if impermeable solutes like glucose, mannitol, etc. are present in ECF, water shifts from ICF to ECF and extracellular osmolality is increased.

iii. So, for every 100 mg/dl increase in glucose, 1.5 mmol/L of sodium is reduced (dilutional hyponatremia). Hence, the plasma sodium is a reliable index of total and effective osmolality in the normal and clinical situations. See summary in Box 30.2.

Box 30.2. Summary of ECF and ICF

1. At equilibrium, the osmolality of extracellular fluid (ECF) and intracellular fluid (ICF) are identical.
2. Solute content of ICF is constant.
3. Sodium is retained only in the ECF.
4. Total body solute divided by total body water gives the body fluid osmolality.
5. Total intracellular solute divided by plasma osmolality will be equal to the intracellular volume.

Regulation of Sodium and Water Balance

The major regulatory factors are the hormones (aldosterone, ADH) and the renin angiotensin system.
Aldosterone secreted by the zona glomerulosa of the adrenal cortex regulates the Na\(^+\) → K\(^+\) exchange and Na\(^+\) → H\(^+\) exchange at the renal tubules. The net effect is the sodium retention.

**Anti-Diuretic Hormone (ADH)**
When osmolality of the plasma rises, the osmoreceptors of hypothalamus are stimulated, resulting in ADH secretion. ADH will increase the water reabsorption by the renal tubules. Therefore, proportionate amounts of sodium and water are retained to maintain the osmolality.

When osmolality decreases, ADH secretion is inhibited. When ECF volume expands, the aldosterone secretion is cut off.

**Renin-Angiotensin System**
When there is a fall in ECF volume, renal plasma flow decreases and this would result in the release of renin by the juxtaglomerular cells (Box 30.3). The factors which stimulate renin release are:

a. Decreased blood pressure
b. Salt depletion
c. Prostaglandins.

The inhibitors of renin release are:

a. Increased blood pressure
b. Salt intake

**Box 30.3. Renin and Rennin are Different**
Kidney secretes Renin; it is involved in fluid balance and hypertension.
Rennin is a proteolytic enzyme seen in gastric juice, especially in children.

**Clinical Significance**
Angiotensin-converting enzyme (ACE) is a glycoprotein present in the lung. ACE-inhibitors are useful in treating edema and chronic congestive cardiac failure. Various peptide analogues of Angiotensin-II (Saralasin) and antagonists of the converting enzyme (Captopril) are useful to treat renin-dependent hypertension. Angiotensin-I is inactive; II and III are active.

Autoregulation
Angiotensin-II increases blood pressure by causing vasoconstriction of the arterioles. It stimulates aldosterone production by enhancing conversion of corticosterone to aldosterone. It also inhibits renin release from the juxtaglomerular cells. The events thus leading to maintenance of sodium and water balance as well as ECF volume are summarized in Figure 30.2.

Atrial natriuretic peptides are secreted in response to the stimulation of atrial stretch receptors. They inhibit renin and aldosterone secretion and eliminate sodium. Table 30.4 gives the physiological stimuli involved in the control of sodium and water balance.

Inherited hypertension: Among the causes of secondary hypertension are a group of disorders with a Mendelian inheritance pattern. The mechanism in every case is the upregulation of sodium reabsorption in the distal nephron, with accompanying expansion of extracellular volume. In one group, the mutations involve the Na-transport machinery in distal convoluted tubule (DCT) cell. Examples include Liddle’s syndrome, with an activating mutation of epithelial Na channel (ENaC); Gordon’s syndrome, with mutations in two regulatory kinases; and apparent mineralocorticoid excess (AME), with an inactivating mutation in the glucocorticoid-metabolizing 11beta-hydroxysteroid dehydrogenase type 2 enzyme (11HD2). In another group, abnormal adrenal steroid production leads to inappropriate stimulation of the mineralocorticoid receptor (MR) in the distal nephron. The pathophysiology may involve inappropriate production of aldosterone [in glucocorticoid-remediable aldosteronism (GRA)], or cortisol (in familial glucocorticoid resistance). Plasma renin activity (PRA) is the appropriate screening tool for all types of inherited hypertension.

Disturbances in Fluid and Electrolyte Balance
Assessment of fluid and electrolyte balance is summarized in Box 30.5. Abnormalities in fluid and electrolyte balance can be expressed in terms of tonicity. When the effective osmolality is increased, the body fluid is called hypertonic and when osmolality is decreased the body fluid is called hypotonic. A classification is given in Table 30.5.

Clinical effects of increased effective osmolality are due to dehydration of cells. A patient may be comatose when serum sodium increases up to 170 mmol/L rapidly; but remains conscious if it occurs gradually, even if serum sodium increases up to 190 mmol/L. A sudden reduction of effective osmolality may cause brain cells to swell leading to headache, vomiting and medullary herniation.

Some important clinical features of electrolyte imbalance are shown in Box 30.6. Different types of abnormalities due to disturbances in fluid and electrolyte balance are given below:

1. Isotonic Contraction of ECF
Results from the loss of fluid that is isotonic with plasma. The most common cause is loss of gastrointestinal fluid, due to:
a. Small intestinal fistulae
b. Small intestinal obstruction and paralytic ileus where fluid accumulates in the lumen
c. Recovery phase of renal failure.
   Since equivalent amounts of sodium and water are lost, the plasma sodium is often normal. For this reason, patient may not feel thirsty. Hemoconcentration is seen. In severe cases, hypotension may occur. Hypovolemia will reduce renal blood flow and may cause renal circulatory insufficiency, oliguria and uremia.
   Compensatory mechanisms will try to restore the volume. Renin-aldosterone system is activated, and selective sodium reabsorption occurs. ADH secretion leads to reabsorption of equivalent amounts of water.

2. Hypotonic Contraction
There is predominant sodium depletion. The causes are
a. Infusion of fluids with low sodium content like dextrose.
   When low sodium containing fluids are infused, the hypo-osmolarity will inhibit ADH secretion resulting in water loss. Since only the excess fluid is lost, the plasma sodium tends to return to normal. Thus, osmolality is restored, but at the expense of the volume. Therefore, in postoperative cases, care should be taken to adequately replace sodium by giving sufficient quantity of normal saline.

b. Deficiency of aldosterone in Addison's disease. The decreased sodium retention lowers the osmolality and inhibits ADH secretion, resulting in contraction of ECF volume. The hypovolemia stimulates ADH secretion, causing further hemodilution and hyponatremia.

3. Hypertonic Contraction
It is predominantly water depletion.
   a. The commonest cause is diarrhea, where the fluid lost has only half of the sodium concentration of the plasma.
   b. Vomiting and excessive sweating can also cause a similar situation.
   c. Diabetes insipidus is a very rare cause.
   d. Hypernatremia is present with a high plasma osmolality. But the volume depletion will reduce renal blood flow and stimulates aldosterone secretion leading to further sodium retention and aggravating hypertension.
   e. The increase in osmolality will stimulate thirst and increase in the water intake. ADH secretion occurs and urine volume decreases.

4. Isotonic Expansion
Water and sodium retention is often manifested as edema and occurs secondary to hypertension or cardiac failure. Hemodilution is the characteristic finding. Secondary hyperaldosteronism may result from any cause leading to a reduced plasma volume in spite of a high ECF volume. This often results from hypoalbuminemia (edema in nephrotic syndrome, protein malnutrition, etc.). In these cases, the water retention causes ADH secretion. The intravascular volume cannot be restored since the low colloid osmotic pressure tends to drive the fluid out into the extravascular space, aggravating the edema. The ECF volume can be restored only by correcting the cause.

5. Hypotonic Expansion
Predominant water excess results only when the normal homeostatic mechanisms fail. There is water retention either due to glomerular dysfunction or ADH excess. The water excess will lower the osmolality. Hypernatremia persists due to the inhibition of aldosterone secretion by the expanded ECF volume. Inhibition of ADH secretion and excretion of large volumes of dilute urine can improve the situation. Cellular overhydration can result in unconsciousness or death.

6. Hypertonic Expansion
It can occur in cases of Conn's syndrome and Cushing's syndrome. The excess mineralocorticoid would produce sodium retention. Resultant increase in the plasma osmolality is expected to increase the ADH secretion, and thereby to restore the osmolality. However, continued effect of aldosterone will cause sodium retention. There is associated hypokalemia which often leads to metabolic alkalosis. Extracellular hypertonicity may lead to brain cell dehydration, leading to coma and death.

SODIUM (Na+)
Sodium level is intimately associated with water balance in the body. Sodium regulates the extracellular fluid volume. Total body sodium is about 4000 mEq. About 50% of it is in bones, 40% in extracellular fluid and 10% in soft tissues. Sodium is the major cation of extracellular fluid.

   Sodium pump is operating in all the cells, so as to keep sodium extracellular. This mechanism is ATP dependent (Chapter 2). Sodium (as sodium bicarbonate) is also important in the regulation of acid-base balance (Chapter 29).

   Normal level of Na+ in plasma is 136-145 mEq/L and in cells 12 mEq/L.

   Normal diet contains about 5-10 gm of sodium, mainly as sodium chloride. The same amount of sodium is daily excreted through urine. However, body can conserve sodium to such an extent that on a sodium-free diet urine does not contain sodium. Ideally dietary sodium intake should be lower than potassium, but processed foods have increased sodium intake.

   Normally kidneys are primed to conserve sodium and excrete potassium. When urine is formed, original glomerular filtrate (175 liters per day) contains sodium 800 gm/day, out of which 99% is reabsorbed. Major quantity (80%) of this is reabsorbed in proximal convoluted tubules. This is an active process. Along with sodium, water is also reabsorbed. Sodium reabsorption is primary and water is absorbed secondarily.

   Sodium excretion is regulated at the distal tubules. Aldosterone increases sodium reabsorption in distal tubules. Antidiuretic hormone (ADH) increases reabsorption of water from tubules.

   Different mechanisms are: (a) Sodium hydrogen exchanger located in the proximal convoluted...
tubules and ascending limb; (b) Sodium chloride cotransporter in the distal tubules (ascending limb); (c) Sodium channels in the collecting duct; and (d) Sodium potassium exchanger in the distal tubule. These are explained in Chapter 29, under renal regulation of pH.

The rate of sodium excretion is directly affected by the rate of filtration of sodium which is decided by the renal plasma flow and blood pressure (acting through atrial natriuretic peptide). The amount reabsorbed is under the control of aldosterone.

**Edema**

In edema, along with water, sodium content of the body is also increased. When diuretic drugs are administered, they increase sodium excretion. Along with sodium, water is also eliminated. **Sodium restriction** in diet is, therefore, advised in congestive cardiac failure and in hypertension.

In the early phases of congestive cardiac failure, hydrostatic pressure on venous side is increased; so water is primarily retained in the body. This causes dilution of sodium concentration, which triggers aldosterone secretion. This is known as **secondary aldosteronism**. Thus sodium is retained, along with further retention of water. This vicious cycle is broken when aldosterone antagonists are administered as drugs.

**Box 30.7. Causes of Hypernatremia**

1. Cushing's disease
2. Prolonged cortisone therapy
3. In pregnancy, steroid hormones cause sodium retention in the body.
4. In dehydration, when water is predominantly lost, blood volume is decreased with apparent increased concentration of sodium.
5. Exchange transfusion with stored blood
6. Primary hyperaldosteronism
7. Elderly patients with poor water intake, and inability to express thirst
8. Excessive intake of salt
9. Drugs:
   - Ampicillin
   - Tetracycline
   - Anabolic steroids
   - Oral contraceptives
   - Loop diuretics
   - Osmotic diuretics

**Hypernatremia**

Increased sodium in blood is known as hypernatremia. Symptoms of hypernatremia include dry mucus membrane, fever, thirst and restlessness. Causes of hypernatremia are enumerated in Box 30.7.

**Hyponatremia**

Decreased sodium level in blood is called hyponatremia. Clinical signs and symptoms of hyponatremia include dehydration, drop in blood pressure, drowsiness, lethargy, confusion, abdominal cramps, oliguria, tremors and coma. However, hyponatremia is often asymptomatic. Causes of hyponatremia are shown in Box 30.8, most important causes being vomiting, diarrhea, and adrenal insufficiency.

**Box 30.8. Causes of Hyponatremia**

1. Vomiting
2. Diarrhea
3. Burns
4. Addison's disease (adrenal insufficiency)
5. Renal tubular acidosis (tubular reabsorption of sodium is defective).
6. Chronic renal failure, nephrotic syndrome
7. Congestive cardiac failure
8. Hyperglycemia and ketoacidosis
9. Excess non-electrolyte (glucose) IV infusion
10. SIADH and defective ADH secretion
11. Pseudo- or dilutional hyponatremia
   - Hyperproteinemia, e.g. myeloma
   - Mannitol
12. Drugs:
   - ACE inhibitors
   - Lithium
   - NSAIDs
   - Vasopressin and oxytocin
   - Chlorpropamide

**Hyponatremia due to water retention** is the commonest biochemical abnormality observed in clinical practice. Hyponatremic patients without edema have water overload and they can be treated by water restriction. Hyponatremia with edema is due to both water and sodium overload and will have to be treated by diuretics and fluid restriction.

**SIADH** (Syndrome of inappropriate secretion of anti-diuretic hormone) is a condition with hyponatremia; normal glomerular filtration rate, and normal serum urea and creatinine concentration. Urine flow rate is less than 1.5 L/day. Symptoms are proportional to the rate of fall of sodium and not to the
**Box 30.9. Diagnostic Criteria for SIADH**

- a. Hyponatremia (<135 mmol/L)
- b. Decreased osmolality (<270 mOsm/kg)
- c. Urine sodium >20 mmol/L
- d. Urine osmolality >100 mOsm/kg.

Absolute value. Diagnostic criteria for SIADH are shown in Box 30.9.

**Hypertonic hyponatremia:** Normal body sodium and additional drop in measured sodium due to presence of osmotically active molecules in serum which cause a shift of water from intracellular to extracellular compartment, e.g. Hyperglycemia can cause a drop in serum sodium level of 1.6 mmol/L for every 100 mg increase in glucose above 100mg/dl. When glucose level exceeds 400 mg/dl this drop will also increase to 2.4 mmol/L for every 100mg increment of glucose above 400 mg/dl. The high level of glucose increases the osmolality leading to hypertonic hyponatremia. A similar effect is seen during mannitol infusion also.

**Normotonic hyponatremia:** Severe hyper-lipidemia and paraproteinemia can lead to low measured serum sodium levels with normal osmolality since plasma water fraction falls. This pseudohyponatremia is seen when sodium is measured by flame photometry, but not with ion selective electrode.

**Hypotonic hyponatremia:** It always reflects the inability of kidneys to handle the excretion of water to match oral intake.

*Treatment* of hyponatremia depends on cause, duration and severity. In acute hyponatremia, rapid correction is possible; but in chronic cases too rapid correction may increase mortality by neurological complications. Effects of administered sodium should be closely monitored, but only after allowing sufficient time for distribution of sodium, a minimum of 4 to 6 hours. Water restriction, increased salt intake, furosemide and anti-ADH drugs are the basis of treatment for hyponatremia.

The correction of hyponatremia and hypertonicity is to be done with care to prevent sudden overhydration and water intoxication. In cases of acute hyponatremia, correction can be quicker. But chronic cases should be treated slowly to prevent cerebral edema. Rapid correction can also cause herniation and permanent neurologic deficit. Appropriate quantity of water should be replaced at a rate so that serum sodium reduction is less than 10 mmol/L in 24 hours.

Serum concentration of sodium is generally measured directly by a **flame photometer or by ion selective electrodes.** When assayed in serum containing hyperlipidemia or hyper globulinemia, there may be an apparent decrease in sodium concentration. In hyperglycemia, serum sodium concentration is reduced by 1.6 mEq/L per 100 mg/dl glucose, because of the shifts of water into extracellular fluid.

**POTASSIUM (K⁺)**

Total body potassium is about 3500 mEq, out of which 75% is in skeletal muscle. Potassium is the major intracellular cation, and maintains intracellular osmotic pressure.

The depolarization and contraction of heart require potassium. During transmission of nerve impulses, there is sodium influx and potassium efflux; with depolarization. After the nerve transmission, these changes are reversed.

The intracellular concentration gradient is maintained by the Na⁺-K⁺ ATPase pump. The relative concentration of intracellular to extracellular potassium determines the cellular membrane potential. Therefore, minor changes in the extracellular potassium level will have profound effects on cardiovascular and neuromuscular functions. The variations in extracellular potassium levels by redistribution (exchange with cellular potassium) are decided by the sodium-potassium pump.

At rest, membranes are more permeable to potassium than other ions. Potassium channel proteins form specific pores in the membrane, through which potassium ions can pass through by facilitated diffusion. Since the protein anions cannot accompany the potassium, further efflux is prevented by the negative potential developing on the intracellular face of the plasma membrane.

**Requirement**

Potassium requirement is 3-4 g per day.

**Sources**

Sources rich in potassium, but low in sodium are banana, orange, apple, pineapple, almond, dates, beans, yam and potato. Tender coconut water is a very good source of potassium.

**Normal Level**

*Plasma potassium level is 3.5-5 mEq/L.* The cells contain 160 mEq/L; so precautions should be taken to prevent hemolysis when taking blood for potassium estimation. The K⁺ in serum is estimated directly by flame photometry or by using an ion selective electrode. Excretion of potassium is mainly through urine. Aldosterone and corticosteroids increase the excretion of K⁺. On the other hand, K⁺ depletion will inhibit aldosterone secretion.

**Potassium excretion**

90% of excess potassium is excreted through kidneys and the rest 10% through GIT. Kidney can lower renal excretion
to 5-10 mmol per day or increase excretion to 450 mmol per day depending on the potassium intake. The majority of the filtered K+ (500 mmol) is reabsorbed in the proximal tubule. The control of secretion occurs in the cortical collecting duct. The exchange of potassium for sodium at the renal tubules is a mechanism to conserve sodium and excrete potassium. This is controlled by aldosterone. Aldosterone and corticosteroids increase the excretion of K+. On the other hand, K+ depletion will inhibit aldosterone secretion.

Yet another factor which influences the potassium level is the hydrogen ion concentration. When there is an increase in hydrogen ion concentration of extracellular fluid, there is a redistribution of potassium and hydrogen between cells and plasma. Hydrogen ions are conserved at the expense of potassium ions and vice versa depending on hydrogen ion concentration. This may lead to a depletion or retention of potassium. (See Chapter 29).

Urinary potassium excretion varies from 30-100 mmol/day, depending on the intake as well as on the amount of hydrogen ions excreted and acid base status. Renal adaptation maintains potassium balance till the GFR drops to 20ml/mt. In chronic renal failure, hyperkalemia is seen since the failing kidney is unable to handle the potassium load.

**Box 30.10. Causes of Hypokalemia**

1. **Increased renal excretion**
   - Cushing’s syndrome
   - Hyperaldosteronism
   - Hyper reninism, renal artery stenosis
   - Hypomagnesemia
   - Renal tubular acidosis
   - Adrenogenital syndrome
   - 17 alpha hydroxylase deficiency
   - 11 beta hydroxylase deficiency

2. **Shift or redistribution of potassium**
   - Alkalosis
   - Insulin therapy
   - Thyrotoxic periodic paralysis
   - (abnormal Na-K-ATPase)
   - Hypokalemic periodic paralysis
   - (abnormal calcium channels)

3. **Gastrointestinal loss**
   - Diarrhea, vomiting, aspiration
   - Deficient intake or low potassium diet
   - Malabsorption
   - Pyloric obstruction

4. **Intravenous saline infusion in excess**

5. **Drugs**
   - Insulin
   - Salbutamide
   - Osmotic diuretics
   - Thiazides, acetazolamide
   - Corticosteroids

**Box 30.11. Causes of Hyperkalemia**

1. **Decreased renal excretion of potassium**
   - Obstruction of urinary tract
   - Renal failure
   - Deficient aldosterone (Addison’s)
   - Severe volume depletion (heart failure)

2. **Entry of potassium to extracellular space**
   - Increased hemolysis
   - Tissue necrosis, burns
   - Tumor lysis after chemotherapy
   - Rhabdomyolysis, crush injury
   - Excess potassium supplementation
   - Malignant hypertension

3. **Redistribution of potassium to extracellular**
   - Metabolic acidosis
   - Insulin deficiency (diabetes mellitus)
   - Tissue hypoxia

4. **Transmembrane shift**

5. **Pseudohyperkalemia**
   - Factitious (K+ leaches out when blood is kept for a long time before separation)
   - Improper blood collection (hemolysis)
   - Thrombocytosis (>400 million/ml)
   - Leukocytosis (>11 million/ml)

6. **Hyperkalemic periodic paralysis**

7. **Drugs**
   - Spiranolactone
   - ACE inhibitors
   - Beta blockers
   - Cyclosporine
   - Digoxin

**Hypokalemia**

This term denotes that plasma potassium level is below 3 mmol/L. A value less than 3.5 mmol/L is to be viewed with caution. Mortality and morbidity are high. Box 30.10 shows the causes of hypokalemia.

**Signs and symptoms:** Hypokalemia is manifested as muscular weakness, fatigue, muscle cramps, hypotension, decreased reflexes, palpitation, cardiac arrhythmias and cardiac arrest. ECG waves are flattened, **T wave is inverted**, ST segment is lowered with AV block. This may be corrected by oral feeding of orange juice. Potassium administration has a beneficial effect in hypertension.

**Redistribution** of potassium can occur following insulin therapy. For diabetic coma, the standard treatment is to give **glucose and insulin**. This causes entry of glucose and potassium into the cell.
and hypokalemia may be induced. K⁺ should be supplemented in such cases.

Redistribution is also seen in alkalosis, where the potassium moves into the cell in exchange for H⁺.

Renal loss of potassium is seen in acute tubular necrosis, renal tubular acidosis and metabolic alkalosis. In metabolic alkalosis, potassium is exchanged with H⁺, in an attempt to conserve H⁺.

In turn, hypokalemia can lead to metabolic alkalosis; this is observed in diuretic therapy, and prolonged vomiting, where K⁺ is lost in exchange for H⁺. Non-renal losses are seen in diarrhea.

Diuretics used for congestive cardiac failure may cause K⁺ excretion; hence potassium supplementation is the standard treatment along with diuretics.

Hyperkalemia
Plasma potassium level above 5.5 mmol/L is known as hyperkalemia. Since the normal level of K⁺ is kept at a very narrow margin, even minor increase is life-threatening.

In hyperkalemia, there is increased membrane excitability, which leads to ventricular arrhythmia and ventricular fibrillation. Hyperkalemia is characterized by flaccid paralysis, bradycardia and cardiac arrest. ECG shows elevated T wave, widening of QRS complex and lengthening of PR interval.

Causes of hyperkalemia are shown in Box 30.11. True potassium excess results from decreased urinary output, increased hemolysis and tissue necrosis. Decreased potassium excretion can occur in mineralocorticoid deficiency, Addison’s disease and potassium sparing diuretics (spironolactone). Potassium channel mutations lead to long-QT syndrome, and cardiac arrhythmias.

Redistribution occurs in metabolic acidosis, insulin deficiency and tissue hypoxia (Table 30.6).

Pseudohyperkalemia is seen in hemolysis, thrombocytosis, leukocytosis or polycythemia; in these conditions, potassium from within the cells will leak out into plasma when the sample is collected. Box 30.13 shows the conditions in which potassium estimations are required.

CHLORIDE (Cl⁻)
Intake, output and metabolism of sodium and chloride run in parallel. The homeostasis of Na⁺, K⁺ and Cl⁻ are inter-related. Chloride is important in the formation of hydrochloric acid in gastric juice (Chapter 26). Chloride ions are also involved in chloride shift (Chapter 22).

Chloride concentration in plasma is 96-106 mEq/L and in CSF, it is about 125 mEq/L. Chloride concentration in CSF is higher than any other body fluids. Since CSF protein content is low, Cl⁻ is increased to maintain Donnan membrane equilibrium.

Excretion of Cl⁻ is through urine, and is parallel to Na⁺. Renal threshold for Cl⁻ is about 110 mEq/L. Daily excretion of Cl⁻ is about 5-8 gm/day.

Box 30.13. When should Potassium Level be Checked?

1. Cardiac diseases
2. Administration of drugs such as diuretics, ACE inhibitors, NSAIDs
3. Diabetic ketoacidosis
4. Receiving large volume of IV fluids
5. Fluid loss (burns, total parenteral nutrition, diarrhea)
6. Renal impairment
7. Weakness of unknown etiology
Hyperchloremia is seen in—
1. Dehydration
2. Cushing’s syndrome. Mineralocorticoids cause increased reabsorption from kidney tubules.
3. Severe diarrhea leads to loss of bicarbonate and compensatory retention of chloride.
4. Renal tubular acidosis.

Table 30.6. Redistribution of serum potassium

<table>

<td>Increased osmolality</td>
</tr>
</tbody>
</table>

Causes for Hypochloremia
1. Excessive vomiting. HCl is lost, so plasma Cl⁻ is lowered. There will be compensatory increase in plasma bicarbonate. This is called hypochloremic alkalosis.
2. Excessive sweating.
3. In Addison's disease, aldosterone is diminished, renal tubular reabsorption of Cl⁻ is decreased, and more Cl⁻ is excreted.

Chloride channels
The CFTR (Cystic Fibrosis Transmembrane Conductance Receptor) chloride conducting channel is involved in Cystic fibrosis. In Cystic Fibrosis, a point mutation in the CFTR gene results in defective chloride transport. So water moves out from lungs and pancreas. This is responsible for the production of abnormally thick mucus. This will lead to infection and progressive damage and death at a young age.
**Milk**

Milk is the only food for the growth of young ones of all mammals. The milk is secreted by the mammary glands. Milk holds a unique place as an almost complete natural food from the point of view of nutrition. The major nutrients lacking in milk are iron, copper and vitamin C. The composition of milk is given in Table 31.1.

**Lactose Synthesis**

Synthesis of lactose in mammary gland is catalyzed by lactose synthase. A galactose unit is transferred from UDP-galactose to glucose.

\[
\text{Epimerase} \quad \text{Lactose synthase} \\
\text{UDP glucose} \rightarrow \text{UDP galactose} \rightarrow \text{Lactose} + \text{Glucose}
\]

The lactose synthase has 2 subunits, a catalytic subunit which is a galactosyl transferase and a modifier subunit that is alpha lactalbumin.

The activity of galactosyl transferase in mammary gland is modified by alpha lactalbumin, so that the galactose residue is transferred to glucose. (Galactosyl transferase in other tissues has the function of catalysing the attachment of galactose to N-acetyl glucosamine units on glycoproteins).

The level of the modifier subunit is under the control of prolactin. Following parturition, the prolactin level rises, and modifier subunit also increases. This would result in the formation of the full enzyme, lactose synthase; then synthesis of lactose occurs. Lactase deficiency is described in Chapter 9; see also Box 31.1.

Net energy content (kilocal /100 ml) of milk of different species is as follows: Human 71, Cow's 69, Buffalo's 117, and Goat's 84.

Human milk has higher carbohydrate content than cow's milk while protein content is less. To humanize cow's milk, protein is to be diluted and carbohydrate is to be added. Thus, to one cup of cow's milk, add half a cup of water and two teaspoons of sugar. This will make it comparable to human milk.

**Lipids in Milk**

The white color of milk is due to the emulsified fat and the calcium caseinate. The lipids of milk are dispersed as small globules. The fatty acids are mainly saturated, but 50% of them are medium chain fatty acids. Medium chain fatty acids are easily digested, absorbed and metabolized (see Chapter 13). The fatty acid make up of milk is butyric acid (4 carbon) 10%; lauric acid (C12) 20%; myristic acid (C14) 20%; palmitic acid (C16) 20%; stearic acid (C18) 15% and oleic acid (C18, 1 double bond) 15%. The yellow color of butter is due to the beta carotenes.

**Proteins in Milk**

A comparison of protein content in milk of different species is shown in Table 31.1. The protein content is generally proportional to the requirement for growth. For example, the

</tbody>
</table>
time for doubling the body weight of a newborn human being is 180 days, but in the rabbit, it is only 6 days. As the growth rate is more in the young rabbit, the rabbit milk also has higher percentage of protein content.

About 80% protein of cow’s milk is casein. It is a phosphoprotein. The phosphate groups are added to the hydroxyl groups of serine or threonine residues. If milk is acidified and pH lowered to 4.6, the casein is precipitated (iso-electric precipitation).

The supernatant whey contains the rest of proteins. The proteins in the whey are lactalbumin, lactoglobulin and lysozyme. In human milk, the casein forms only about 40% of milk proteins, and the rest 60% is present in the whey. IgA (140 mg/dl) has the highest concentration among the immunoglobulins. IgM and IgG are also present in small amounts.

**Minerals in Milk**

Milk has a high content of calcium, phosphorus, sodium and potassium; but is poor in iron and copper. Hence young infants fed exclusively on milk may develop iron deficiency anemia. Semisolid diet should be started in children after 3 months of age, so that anemia may be prevented. A comparison of the mineral content of human and bovine milk is shown in Table 31.2.

**Colostrum (Colostral Milk)**

It is secreted during the first few days after parturition. Colostrum coagulates on heating, whereas fresh milk does not. This coagulum forms a surface film containing casein and calcium salts. Colostrum is mildly laxative, which helps to remove meconium from the intestinal tract of the infant. The change from colostrum to milk occurs within a few days after the initiation of lactation.

The proteins present in colostrum are predominantly immunoglobulins. In the case of cow, these immunoglobulins are readily absorbed by the calf, and give protection to the young animal. However, in human beings there is no definite evidence for absorption of antibodies by the suckling infant.

**CEREBROSPINAL FLUID (CSF)**

The CSF is found within the subarachnoid space and ventricles of the brain, as well as around the spinal cord. The fluid originates in the choroid plexus and returns to the blood in the vessels of the lumbar region.

The total volume of fluid is about 125 ml. It is a transudate or ultrafiltrate of plasma. The composition of the fluid is given in Table 31.3. CSF has the chloride concentration higher than the plasma. This is in accordance with the Gibbs-Donnan equilibrium (see Chapter 1). Because the concentrations of non-diffusible anions like proteins are lower in CSF than in the plasma, as a compensation, the chloride ions are increased.
Biochemical Analysis of CSF

The protein concentration is usually 10-30 mg/dl, out of which about 20 mg/dl is albumin, and globulin is about 5-10 mg/dl.

In bacterial infections of the meninges, the protein concentration is increased. But in such cases, the neutrophil cell count is also increased.

In viral infections, the protein concentration is not significantly increased, but mononuclear cells are abundant.

In brain tumors, albumin level is raised, but cell count is normal; this is called albuminocytological dissociation.

Electrophoresis of CSF

Normal CSF shows 60% albumin, 8% gamma globulins and 32% other globulins. The electrophoretic pattern is abnormal when IgG synthesis in brain is increased. Oligoclonal bands are found in such conditions.

In multiple sclerosis, the characteristic finding is an increase in globulin levels, especially IgG fraction. Serum protein concentration is also measured and the IgG index is calculated as:

\[
\text{IgG index} = \frac{\text{CSF IgG} \times \text{Serum albumin}}{\text{Serum IgG} \times \text{CSF albumin}}
\]

In multiple sclerosis, the index is increased, showing an absolute increase in IgG level. The cause is believed to be the increased synthesis of IgG in CNS.

Glucose Level in CSF

Normal level of glucose in CSF is 50-70 mg/dl, which is lower than the plasma level. Hence estimation of plasma glucose along with CSF glucose is always done to avoid misinterpretation due to a change in the plasma glucose. Elevated levels are seen in diabetes mellitus. In bacterial meningitis, however, the glucose level is far lower when compared to the plasma, because it is metabolized by bacteria. The diagnostic findings in different diseases are given in Table 31.3.

AMNIOTIC FLUID

Amniocentesis is the process by which amniotic fluid is collected for analysis. Examination of amniotic fluid is of importance in prenatal diagnosis. The normal composition of amniotic fluid is given in Table 31.4.

Lung Maturity

The lung maturity is assessed by measuring the lecithin-sphingomyelin (L/S) ratio, which is an index of the surfactant (surface tension lowering complex) concentration in amniotic fluid. In late pregnancy, the cells lining the fetal alveoli start synthesizing dipalmitoyl-lecithin so that the concentration of lecithin increases, whereas that of sphingomyelin remains constant. As a result, as the fetal lung matures, the lecithin sphingomyelin (L/S) ratio rises. An L/S ratio of 2 is taken usually as a critical value.

Hemolytic diseases: The measurement of bilirubin in amniotic fluid by direct spectrophotometry is useful in early detection of hemolytic disease of the newborn.

Measurement of AFP: Alpha fetoprotein (AFP) estimation in the amniotic fluid is important in prenatal detection of neural tube defects. AFP is described in Chapter 51. Elevated levels in both the amniotic fluid and the maternal serum are strongly suggestive of neural tube defects of fetus.

Other metabolites: Estimation of cholinesterase iso-enzyme (fast moving band) in amniotic fluid confirms open neural tube defects when tested before 22-24 weeks of gestation. Other abnormal metabolites estimated in amniotic fluid include phenylalanine (to detect phenyl ketonuria) and methyl malonic acid in suspected cases of inborn errors of metabolism.

CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:

1. Prenatal diagnosis
2. AFP, hCG, uE3, DIA, PAPP-A
3. Newborn screening
4. Investigations for metabolic disorders
5. Pre-analytical variables
6. Anticoagulants and preservatives
7. Quality control in the laboratory
8. Accuracy, precision, specificity, sensitivity
9. Total quality management
10. Quality control charts
11. External quality assurance

PRENATAL DIAGNOSIS

About 2% of livebirths are associated with a genetic defect. In addition, genetic disorders are also a major cause of pregnancy loss as well as perinatal mortality and morbidity. Taking a detailed family history is very important in prenatal genetic evaluation, permitting the counselor or physician to identify problems for which a couple may be at risk (See Box 32.1). One of the most important of these is a three-generation family history analysis (pedigree analysis). Details to be obtained include miscarriage, neonatal or early life death, consanguinity as well as specific information of mental retardation, anemia and congenital anomalies.

Amniocentesis

Prenatal diagnosis of inborn errors of metabolism can be made by enzymatic assays of cultured amniocytes. Diagnosis of these disorders is offered only when couples are at substantial risk, e.g. if the couple already had a child affected by an inherited disorder, if one of the parents is affected by an autosomal or X-linked dominant disorder or when carrier testing reveals that both parents carry a recessive trait.

Chorionic Villi Sampling (CVS)

The most common indications for CVS are advanced maternal age, or a biochemical or genetic disorder indicated by molecular markers. CVS has the advantage of early diagnosis, allowing earlier intervention. The genetic make up of the placenta is identical to that of the fetus. For this reason, chorionic villi may be utilized to determine the chromosomal, enzymatic, or molecular genetic status of the fetus.

Cytogenetics and Molecular Cytogenetics

Samples include amniocentesis, transabdominal and transcervical chorionic villus sampling (CVS), fetal blood sampling and fetal skin biopsy. Cytogenetic analysis may be done with fluorescence in situ hybridization (FISH) for common chromosomal aneuploidies involving chromosomes 13, 18, 21, X, and Y. Other molecular cytogenetic tests permit evaluation and further characterization of more subtle abnormalities, including microdeletions, marker chromosomes, translocations, deletions, inversions, and subtelomeric deletions. Microarrays (DNA chips) with genomic clones are being developed and hold promise for providing a replacement for FISH for microdeletion syndromes and subtelomere analysis.

Biochemical Screening

They are cheap, easy, quick and reliable. But they do not give definitive answer. On the other hand diagnostic tests are performed only on “risk” population, they are generally expensive; but will give definitive answer.

Maternal Serum Screening

Prenatal screening has become standard obstetric practice in all pregnancies at risk. Four analytes—alpha-fetoprotein

Box 32.1. Common Medical Indications for a Referral to a Genetic Counselor

1. Advanced maternal age (greater than 35 years)
2. Positive maternal serum screening
3. Patient or family member with a known mendelian disorder
4. Prior pregnancy with a chromosomal disorder
5. Family history of mental retardation or birth defect
6. Fetal anomalies or markers by sonogram
7. Recurrent pregnancy loss/stillbirth
8. Infertility
9. Ethnic-based carrier screening
10. Consanguinity
(AFP), human chorionic gonadotropin (hCG), unconjugated estriol (uE3), and inhibin—are estimated. The triple screen (AFP, hCG, uE3) is done during the second trimester between 14 and 18 weeks. Neural tube defects, trisomy 21 and trisomy 18 are detected. Each laboratory has to use its own data to establish median values for each marker (analyte) for each week of gestation. Ideally the median is to be calculated with results from 200 samples.

Alpha fetoprotein (AFP) is the major serum protein of the fetus synthesized by the fetal liver and yolk sac. There is a steady increase in AFP level in maternal serum from 10th week of gestation and reaches a peak by 25 weeks of gestation in unaffected pregnancy. Then the maternal serum alpha fetoprotein (MSAFP) steadily declines until term. In fetal serum and amniotic fluid, the AFP level reaches a peak by 9th week of gestation and then slowly falls till term. In NTD, the AFP is increased but in chromosomal aneuploidy it is decreased.

Human Chorionic Gonadotropin (hCG) is a glycoprotein hormone produced during normal pregnancy by the trophoblast and placenta. hCG appears in maternal serum by 6 to 8 weeks and reaches a peak by 10 weeks. By the second trimester it falls to a constant level by 18 to 20 weeks. hCG is a heterodimer having alpha and beta subunits of which the beta subunit is specific for hCG. A marked increase of about twice the normal value was found in pregnancies with trisomy 21 during the second trimester. Free beta hCG was increased during the 1st trimester in pregnancies with trisomy 21 during the second trimester. Total hCG was found to be a poor marker in the first trimester, but an adequate marker during the second trimester. Free beta hCG on the other hand is higher from 10 to 18 weeks.

Hence the present suggestion is to combine the markers of first and second trimester in maternal serum. The suggested protocol for screening is given in Box 32.2. Follow-up of patients with screen positive is shown in Box 32.3.

X-linked Disorders
Ornithine carbamoyl transferase deficiency, Hunter disease, hypophosphatemic rickets and Fabry’s disease are X-linked. Biochemical methods are seldom completely accurate in identifying X-linked carriers (females) because of the randomness of the X inactivation that sometimes may lead to a normal biochemical result. Hence, activity levels may not correlate with clinical expression. Males, on the other hand, have only one X chromosome and they are either hemizygote normal with activity within the normal range. Some X-linked disorders are lethal in utero in males and severely or completely impair reproduction in females. Microphthalmia with linear skin defects syndrome and Rett syndrome are such disorders.

Biochemical Genetics
Biochemical tests for diagnosis of inherited metabolic disorders consist of identification of abnormal metabolites or abnormal levels of metabolites or the defective or deficient gene product. Fetal tissues (chorionic villi and fetal liver biopsy) or cells (trophoblasts, amniotic fluid cells, fetal erythrocytes, and leukocytes) are used for analysis of the enzyme or other protein primarily involved.

Testing of leukocytes or cultured skin fibroblasts from the parents, the index case and unaffected siblings can provide valuable information on the respective values of different genotypes within a particular family. It may prove to be a
reliable means for identification of carriers among members of the extended family.

**Enzyme Assays**
Direct demonstration of abnormality or deficiency of the gene (molecular techniques) or gene product (biochemical techniques) is the preferred diagnostic approach. Prenatal detection of citrullinemia and argininosuccinic aciduria and characterization of the mutant enzyme (argininosuccinate synthase and argininosuccinate lyase, respectively) are carried out in trophoblast or amniotic fluid cell cultures by measuring the incorporation of 14C from citrulline into arginine residues of newly synthesized protein.

Cystinosis, an autosomal recessive lysosomal storage disease, can be diagnosed prenatally by pulse labeling of cultured cells with [35S] cysteine from chorionic villi. Many families prefer diagnosis at birth and immediate initiation of therapy if the child is affected. This is done by measuring the cysteine content of the placenta or the cord blood leukocytes.

Molecular genetics techniques like Q-RT-PCR, Southern blotting, linkage analysis as well as mutation analysis and a variety of PCR-based techniques have been used.

**NEWBORN SCREENING**
Screening newborn infants for phenylketonuria (PKU) was the first, large-scale genetic screening initiative to be widely adopted. High-risk individuals should be detected by a simple, inexpensive test with high sensitivity (the proportion of affected infants with a positive screening test), specificity (the proportion of unaffected infants with a negative test), and predictive efficiency (ratio of true-positive to false-positive tests). For screening tests for PKU, see Chapter 17, under phenylketonuria.

**Box 32.2. Suggested Protocol for Screening**
1. Measurements of NT and PAPP-A are made in the first trimester, but not interpreted or acted upon until the second trimester.
2. In the second trimester, a second serum sample is drawn and quadruple test performed.
3. Results for all the six tests, NT, PAPP-A, AFP, uE3, hCG and DIA are combined into a single risk estimate for interpretation in the second trimester.
4. 85% detection rate for DS with only 1% false positive is achieved.

(NT = Nuchal translucency; PAPP-A = Pregnancy associated plasma protein-A; AFP = Alpha fetoprotein; uE3 = unconjugated estriol; hCG = human chorionic gonadotropin; DIA = Dimeric inhibin A)

**Box 32.3. Follow-up of Patients with Screen Positive Results**
1. Genetic counseling if patient is screen positive.
2. For moderately elevated results (MoM 2-3), a second test should be done.
3. If second test is negative; screen is taken as negative.
4. If second test also gives elevated results, further diagnostic testing is to be done.
5. USG, amniocentesis and analysis of amniotic fluid for acetyl choline esterase to confirm neural tube defects.
6. Amniotic fluid AFP results may give false positive due to contamination by fetal blood, hence confirmed by acetyl choline esterase. AchE is not normally present in amniotic fluid, but appears in open neural tube defects.
7. In cases of suspected chromosomal aneuploidy, fetal karyotyping is to be done.

**Screening Technology**
Screening tests are: 1. Guthrie test for PKU (phenyl ketonuria). 2. Immunoassay for TSH (congenital hypothyroidism); 17 alpha hydroxy progesterone (congenital adrenal hyperplasia). 3. Tandem mass spectrometry useful for most other disorders.

**Tandem Mass Spectrometry (MS-MS)**
The introduction of MS-MS for newborn screening represents a technological breakthrough. Blood obtained by heal-prick is applied to a filter-paper, four to six circles approximately 1 cm in diameter, allowed to dry in air, and sent to a screening laboratory for analysis. Small circles of blood-soaked filter paper are punched out and metabolites extracted with organic solvents. The samples are derivatized, usually by formation of the butyl esters, prior to injection into the tandem MS-MS for analysis. Tandem mass spectrometry is described in Chapter 54.

The sensitivity of tandem MS-MS testing in screening for PKU is greater than the sensitivity of any bacterial inhibition or biochemical method for measuring blood phenylalanine levels.

The power of newborn screening by tandem MS-MS is enormously enhanced by the ability to analyze several metabolites simultaneously in the same blood specimen. Newborn screening programs tend to focus on three groups of metabolites: amino acids, fatty acid oxidation intermediates, and short-chain organic acids.

**LABORATORY INVESTIGATIONS TO DIAGNOSE METABOLIC DISORDERS**
They include routine biochemical tests like measurements of arterial blood gases, plasma electrolytes, glucose, urea,
creatinine, liver function tests, routine hematology tests, and various endocrinology tests, such as thyroxine, tri-iodothyronine, thyroid-stimulating hormone. Studies also include measurements of lactate, pyruvate, amino acids, 3-hydroxybutyrate, acetoacetate, and free fatty acids in plasma; analyses of urinary organic and amino acids; tests for mucopolysaccharides and oligosaccharides in urine; and measurements of certain trace elements, such as copper. The ultimate specific diagnosis of inherited metabolic disease generally requires the demonstration of a primary biochemical abnormality, such as a specific enzyme deficiency, or mutations that have been shown to cause disease.

A useful first step in helping to focus the laboratory investigation of possible inherited metabolic diseases is to try to determine whether the disease is due to a defect in the metabolism of water-soluble intermediates, such as amino acids, organic acids, or is likely due to an inherited defect in lysosomal, mitochondrial, or peroxisomal metabolism (defect in organelles).

Studies directed at the classification of the disease processes are shown in Box 32.4. Definitive diagnosis generally requires further in vitro metabolic studies, usually specific enzyme assay.

**Lactic Acidemia**

Box 32.5 gives the different conditions in which lactate/pyruvate ratio is abnormal. Deficiency of pyruvate dehydrogenase complex is the most common cause of lactic acidemia. E1, E2, E3, X-lipoate and PDH phosphatase are the causes. E1 is most common. In severe cases, death occurs at neonatal period. In moderate cases, profound mental retardation is observed. In mild cases, developmental delay is noticed.

Pyruvate carboxylase (PC) deficiency may be (A) Moderate lactic acidosis and delayed development. (B) Complex form with lactic acidosis, hyperammonemia, citrullinemia, hyperlysinemia, where death occurs in 3 months. (C) Mild presentation, where episodic lactic acidemia, with mild mental retardation is seen.

**Plasma and Urinary Amino Acids**

They are useful in the diagnosis of specific and generalized aminoacidurias. Disorders of amino acid metabolism are classified in Box 32.6. See also Table 17.2. Further, Box 32.7 shows the secondary abnormalities seen in plasma or urine amino acid levels.

**Organic Acidurias**

Box 32.8 shows the organic acidurias. A combination of screening with GC-MS is employed for the diagnosis.

**Oligosaccharide Screening Tests**

Patients with GM1 gangliosidosis, galactosialidosis, or Schindler disease are rarely missed; the urinary oligosaccharide abnormality is generally obvious. On the other hand, the excretion of oligosaccharides by patients with other glycoproteinoses is variable. Urine of patients with alpha-mannosidosis, alpha-fucosidosis, Sandhoff disease, or aspartyl gluco...
saminuria usually shows increased amounts of oligosaccharides. Urine specimens from patients with beta-mannosidosis, I-cell disease (mucolipidosis II) or pseudo-Hurler poly-dystrophy (mucolipidosis III) generally do not contain excess amounts of oligosaccharides. Oligosacchariduria is a feature of some glycogen storage diseases, such as Pompe’s disease (GSD II). Breast-fed neonates also commonly show the presence of oligosaccharide bands that would be interpreted as abnormal in older children.

Test for ketone bodies (Rothera’s test) is described in Chapter 11; Benedict’s test for reducing sugar is described in Chapter 6 and cyanide nitroprusside test is given in Chapter 15.

**Ferric chloride test:** Phosphate precipitating agent (PPA) is prepared by 2.2 g MgCl₂, 1.4 g NH₄Cl, 2 ml conc. NH₄OH in 100 ml distilled water. To 1 ml PPA, add 4 ml filtered urine. Solution filtered again. Urine is then acidified with 2-3 drops conc. HCl. Then add 2-3 drops of 10% ferric chloride, drop by drop. Interpretation of color development is shown in Table 32.1.

**Dinitrophenyl hydrazine (DNPH) test:** 0.4 gm% of DNPH is prepared in IN HCl. Equal quantities of filtered urine and DNPH reagents are mixed. A yellow white precipitate within 5 min is positive. Yellow color is imparted by reagent, the presence of precipitate only is positive. All keto acids can give positive test. This is generally used for diagnosing branched chain ketoaciduria, Maple syrup urine disease and isovaleric aciduria

**CPC Test:** This is for mucopolysaccharides. The reagent is prepared by 50 g/L cetyl pyridinium chloride (CPC) in 1 mol/L citrate buffer (pH 6.0). To 1.8 ml of CPC reagent, add 0.2 ml filtered urine. Stand for 30 min. A white precipitate is indicative of mucopolysaccharide excretion. Optical density at 430 nm <0.10 after 30 min is negative, whereas >0.1 is indicative of MPS, especially, Hurler’s and Hunter’s syndrome. Other mucopolysaccharidoses can be identified by Alcian blue staining and 2D gel chromatography.

### Box 32.6. Classification of Disorders of Amino Acid Metabolism

1. Hyperphenylalaninemas
2. Hypertyrosinemias
3. Disorders of histidine metabolism
4. Disorders of proline and hydroxyproline
5. Hyperornithinemas
6. Urea cycle disorders
7. Errors of lysine metabolism
8. Disorders of branched chain amino acids and keto acids
9. Disorders of trans-sulphuration
10. Nonketotic hyperglycinemia
11. Other disorders

### Box 32.7. Secondary Abnormalities in Plasma or Urine Amino Acids

- Increased plasma alanine: Lactic acidosis
- Beta amino isobutyric aciduria: Marked tissue destruction (burns, leukemia, surgery, etc.)
- Generalized amino aciduria: Proximal renal tubular dysfunction
- Increased plasma methionine, tyrosine: Commonly associated with hepatocellular disease.
- Methioninuria: Resulting from ingestion of d-methionine in synthetic infant formulae
- Glycylprolinuria or prolylhydroxyprolinuria: Active bone disease
- Increased plasma threonine: Ingestion of infant formulas with high whey to casein ratio
- Increased plasma cystathionine: Vitamin B₆ deficiency

### Box 32.8. Disorders of Organic Acid Metabolism

1. Alkaptonuria
2. Branched chain organic acidurias
3. Propionic aciduria, methylmalonic aciduria
4. Defect in lysine oxidation: 2-keto adipic acidemia and glutaric acidemia
5. Gamma glutamyl cycle disorders
6. Lactic acidemias
7. Mitochondrial fatty acid oxidation disorders
8. Oxidative phosphorylation disorders
9. Glutaric acidemia type II (respiratory chain)

### Table 32.1. Interpretation of ferric chloride test

Ninhydrin test: All amino acids will answer this test. Urine is boiled with ninhydrin reagent. Light blue to dark blue (purple) color may be obtained in the presence of amino acids. Negative test rules out aminoacridia. Amino acid color reactions and thin layer chromatography may be undertaken to identify specific amino acids. Once aminoacridia has been detected, it has to be quantified by HPLC, preferably on both blood and urine samples.

Test for porphobilinogens: Mix equal volumes of fresh urine and Ehrlich’s reagent. Allow to stand for 3 minutes. Add saturated aqueous sodium acetate solution (two volumes) and stand for 3 minutes. Add a few ml of chloroform and shake thoroughly. Porphobilinogens form a red aldehyde compound insoluble in chloroform. Any red color remaining after chloroform extraction (in aqueous phase) is indicative of porphobilinogens. It is positive in acute intermittent porphyria. Porphyrins also give a red fluorescence in ultraviolet light.

REFERENCE VALUES
A patient’s results have to be compared with the reference values to either confirm a clinical diagnosis or exclude a particular disease. Reference values and normal values should not be considered as synonymous. The term “normal” was used arbitrarily in the past, but was found to be ambiguous when used in a statistical sense. As per IFCC (International Federation of Clinical Chemistry and Laboratory Medicine) recommendations, reference values are based on that of a reference individual.

The value obtained by analysis of a particular sample is referred to as the observed value, which is compared with the reference value to arrive at a decision. There are different types of reference values, which are population-based or subject-based. Subject-based reference value indicates previously observed values in the same subject. The reference values may be univariate or multivariate. For instance, we can interpret the values of TAG and cholesterol in serum either separately or together. The conclusions drawn may be different.

The reference values are established in healthy individuals. Reference values are based on application of statistical methods to values generated in the laboratories. The normal values are derived based on the distribution of these values. Direct sampling methods where individuals are selected based on inclusion criteria or where existing data satisfying inclusion criteria provide reliable reference values. Screening large populations to get reference groups is also a possibility. Ideally the group of reference individuals should be a random sample (equal chance of being selected).

There are three types of reference intervals: tolerance interval, prediction interval and interpercentile interval. When the sample size is large, the numerical difference between these intervals is negligible.

Interpercentile interval is the easiest to estimate and recommended by IFCC. It is the interval bounded by two percentiles of the reference distribution. A percentile denotes a value that divides the reference distribution such that a specified percentile of values have magnitudes less than or equal to the limiting value. If a value of 4 mmol/L is the 97.5 percentile of serum potassium, 97.5% of the values are equal to or below that value. 2.5% of the values are cut off in both tails of the reference distribution when the reference interval is conveniently defined as 95% interval.

The precision of the percentile depends on the number of values. Fewer the values, lesser is the precision. Confidence interval of the percentile is the limits within which the true percentile is located with a specified degree of confidence. The theoretical lower limit of the sample size required for the estimation of a precise reference value is usually 120.

A diagnostic criterion is a cut off value for making a diagnosis, e.g. hypoglycemia. Prognostic limit is a value which indicates a definite improvement or deterioration of the condition, e.g. plasma glucose after insulin. Therapeutic value and toxicity threshold are applicable in cases of analytes like lithium where therapeutic effectiveness and onset of toxicity are within very narrow limits.

Reference Values and Observed Values
In actual clinical practice often we have to compare several observed values with their reference intervals. For analytes which are under hormonal or metabolic control, there may be subject-based variation; intra-individual or inter-individual (e.g. Progesterone levels in pregnant women).

Each laboratory should have their own established reference values and the observed value and reference value may be reported on the same report sheet for purposes of comparison and clinical decision making.

The observed value may also be expressed by a statistical distance measure. Standard deviation (SD) unit is calculated as the difference between the observed value and the mean of the reference values divided by their standard deviation.

The variations observed in the level of alpha fetoprotein, beta hCG and estradiol in maternal serum depend on the period of gestation. So the reference values for these parameters must be available in laboratories on a weekly basis. The reference values are compared with the observed values and expressed as Multiple of Median (MOM) values. The decision making, whether to continue the pregnancy or terminate, is based on the MOM values for a particular subject. This is obtained by dividing each test result by the median for the relevant gestational week. Here is a typical example where the establishment of reliable reference values is crucial in clinical decision making.

PREANALYTICAL VARIABLES
Preanalytical variability is defined as errors which occur when nonanalytical factors change the concentrations of analytes, so that the results do not reflect the condition of the patient. Preanalytical variability may be due to a) precollection causes, or
b) blood collection causes. Important types of preanalytical variables are shown in Box 32.9. Clinicians should know about these variables; then only a correct interpretation is possible. Preanalytical variables may be controllable so that their effect can be minimized.

**Time of collection**
Fasting samples are used for insulin, C-peptide, gastrin and HDL cholesterol. Time of collection is important for androstenedione and 17-hydroxy progesterone that are collected in the afternoon.

**Posture**
Upright posture decreases blood volume to about 10%. A change in posture from lying to upright increases secretion of catecholamines, aldosterone, renin and ADH. Catecholamine secretion doubles within 10 minutes and aldosterone and renin doubles in 1 hour. Release of intracellular potassium from muscle causes an increase in potassium after 30 minutes of standing.

**Box 32.9. Types of Preanalytical Variables**

- **Test conducted.** The appropriate test should be requested and performed.
- **Patient identification.** The labeling of specimen may be improper. Corrected by bar coding.
- **Turn around time (TAT).** The time required from the specimen reaching the laboratory and the result being dispatched should be kept minimum. Time of arrival, completion of test and dispatch should be noted.
- **Laboratory logs.** Entry of patient and test details in laboratory registers and computers.
- **Transcription errors.** Substantial number at different levels especially if sample number is high. Electronic identification and tracking of specimens check digits, units and test correlation.
- **Patient preparation.** Improper standardization of the collection time and manner of collection.
- **Specimen collection.** Container, anticoagulant, time taken to send specimen to laboratory corrected by using vacuutainer tubes and collection of samples by laboratory personnel.
- **Separation, aliquoting.** Monitoring of the performance of the centrifuge, container used for storage. Emergency specimens to be processed as fast track and given priority in stat analysers.
- **Personnel.** Variation from person to person. Safety precautions for all specimens. Throughput time (time taken from arrival of specimen to completion of assay) to be monitored on a weekly or monthly basis.

**Prolonged bedrest**
Extracellular fluid volume decreases after a few days of bedrest. Hematocrit value increases about 10% within 4 days. When bedrest is prolonged, the level of proteins and protein bound constituents is decreased. Urinary excretion of catecholamines, cortisol, VMA and blood urea decreases by 2-3 weeks of bedrest. Calcium, sodium, potassium, phosphate and sulfate excretion increases and takes about 3 weeks to return to normal.

**Exercise**
After moderate exercise there is a stress response that increases blood glucose. Plasma pyruvate and lactate are increased 2-fold. Arterial pH and PCO$_2$ decrease. Slight increase is seen in creatinine, uric acid, CK, LDH, AST and aldolase. Those who are in the habit of walking about 4 hours per week have 5% lower cholesterol and 3.5% higher HDL cholesterol.

Strenuous exercise causes more pronounced effects on the same parameters. Plasma cortisol is elevated without any pronounced diurnal variation. Aldosterone, growth hormone and prolactin are increased while pH, bicarbonate and PaO$_2$ are decreased.

**Circadian variations**
Several analytes in body fluids exhibit diurnal variation (Circadian rhythm) in their secretion. Variations in level are, therefore, to be expected depending on the time of collection. This mainly applies to hormones that are secreted in a pulsatile manner (Table 32.2).

**Diet**
Diet has a significant effect on several analytes. A high protein diet causes a doubling of urea concentration within 4 days. A high fat diet depletes the nitrogen pool, but serum TAG increases, but the serum cholesterol does not reflect short-term changes in the diet. The ingestion of a meal elevates the plasma levels of glucose and lipids. Phosphate level falls during the postprandial state since phosphate enters the cells for metabolizing glucose. Since most of the parameters are assayed in the same sample, a fasting sample is preferred. A minimum of 10 to 12 hours fasting prior to collection of samples is required. The alkaline tide of plasma following a meal is reflected in the serum bicarbonate level.

**Nature of the diet** may also have some effects like high fiber diet (glucose, cholesterol, calcium, TAG), presence of caffeine (catecholamine and metabolites), banana (serotonin and 5HIAA). Vegetarians in general have low LDL-C, but HDL-C is more. Urinary pH is higher in vegetarians compared to meat eaters. Urea and uric acid levels are also lower in...
**Table 32.2. Circadian variations in analytes**

<table>
<thead>

</tbody>
</table>

Vegetarians. Lifestyle has a notable effect on blood parameters. Smoking and alcohol increase the level of TAG. Chronic alcoholism increases GGT levels.

**Pharmacological agents**

Several drugs can alter blood parameters. Any intramuscular injection of drugs can elevate CK and aldolase levels. Oral contraceptives elevate ALT and alter estrogen and progestosterone levels. Diuretic use is known to decrease sodium and potassium levels and increase calcium. Phenytoin decreases calcium, and phosphate, but elevates ALP. Statins and aspirin are likely to affect hepatic enzyme levels and coagulation parameters respectively.

**Noncontrollable variables**

Factors like age, sex, race, affect several parameters and reference values are established taking these variables under consideration. Physiological states like pregnancy, lactation, menstrual cycle, environmental factors like altitude, temperature, psychological factors like stress and shock, underlying causes like obesity, fever, trauma and transfusion can all cause significant variation in several specific parameters. Separate reference standards are maintained for children, adult and aged. If the relevant information is provided in the laboratory request form also, the reporting and interpretation will be more accurate.

**Specimen Collection**

Use of vacutainer tubes is the standard procedure in specimen collection. The ease of barcoding the tubes and using them as specimen tubes in autoanalysers have decreased the chances of variation at this stage.

**Plasma values** are higher than serum values in the case of calcium and chloride. Plasma values are less than serum values for albumin, ALP, AST, bicarbonate, creatine kinase, urea, uric acid, sodium glucose (5%), phosphate (7%) and potassium (8.4%).

**Arterial blood** is used for ABG (arterial blood gas) analysis. Most of the other investigations use venous blood. However, **capillary blood** gives higher values than venous for glucose and potassium, lower values for bilirubin, calcium, chloride and sodium, but no difference for urea and phosphate.

**Hemolysis**

Vigorous suction by the syringe during the blood collection, or forceful transfer from the syringe to the container may cause hemolysis of blood. Even minimal hemolysis will alter the values of potassium level. The presence of visually appreciable hemolysis is seen when the hemoglobin level is more than 200 mg/L. Enzymes like aldolase, LDH, ACP, ICD and electrolytes potassium, magnesium and phosphate are elevated by the presence of hemolysis. Hemolyzed samples give falsely low values for bilirubin and special care is to be taken when blood is collected for neonatal bilirubin estimation.

**Anticoagulants**

Serum from coagulated blood is the specimen of choice for many assay systems. Commonly used anticoagulants are heparin, EDTA, oxalates, citrate and fluoride. Of these, lithium heparin is best suited for most of the biochemical estimations. All other anticoagulants chelate calcium and hence unsuitable for calcium estimation. The possibility of enzyme inhibition especially creatine kinase, ALP, ACP, amylase and LDH is observed with several of these anticoagulants. Oxalates are unsuitable for estimation of sodium and potassium also.

**Heparin** is the most widely used anticoagulant for clinical chemical analysis. It interferes the least with test procedures. Ethylene diamine tetra acetic acid (EDTA) is a chelating agent, and is particularly useful for hematological examination because it preserves cellular components of the blood. It may affect some of the clinical chemistry tests.

**Sodium fluoride** is usually used as a preservative for blood glucose by inhibiting the enzyme systems involved in the glycolysis. Without an antiglycolytic agent, the blood glucose concentration decreases about 10 mg/dl per hour at 25°C and false results may be obtained. However, such serum should not be used for enzymatic assays.

**Citrate** is widely used for coagulation studies. Oxalate inhibits blood coagulation by forming insoluble complexes with calcium ions. Potassium oxalate may be used at a concentration of 1-2 mg/ml; at higher concentrations, oxalate may cause hemolysis.

**Storage and preservation of specimens**

Plasma or serum should be separated from the cells as soon as possible, and certainly within 2 hours. If the specimen cannot be analysed at once, the separated serum should be stored in capped tubes at 4°C. When a sample is to be stored beyond a week, it should be kept at –20°C in a freezer.

For assays that are done in batches, the specimens should be properly preserved to avoid erroneous results.
Some examples are given in Table 32.3. Table 32.4 gives some examples of preservatives to be used.

**Transport of specimens**

Transport from a referring laboratory to a reference laboratory should be presumed to take 72 hours. The primary container that holds the specimen should be polypropylene or polyethylene with teflon lined screw cap. Glass should not be used, as it is liable to be broken during transport. The container should be properly sealed. Specimens transported by air should be protected from changes of pressure and temperature and the possibility of vibration. Stryoform containers are suitable since frozen and refrigerated samples can also be sent in these. The container should be at least 1" thick with proper insulation vents to prevent explosion due to CO2 build up. Dry ice (solid CO2) can be used, but airlines have restrictions for its use.

**Care of infected specimens**

Samples from patients, who are positive for HpBsAg (hepatitis B surface antigen) (infective hepatitis) or for HIV (AIDS patients), should be kept separately, in protected bags. The specimen is disposed off properly. Any serum specimen may be from patients of these diseases. Therefore, all serum or blood samples should be handled as if they are infected and adequate precautions should be taken.

**Urine collection**

An early morning fasting specimen is generally the most concentrated specimen. Therefore, it is preferred for microscopic examination and for the detection of proteins and beta chorionic gonadotropin.

**Timed urine specimen**

Usually, urine sample is collected for the 24-hour period. This will minimize the influence of short-term biological variations and diurnal rhythms. Generally, collection of urine samples is done from 6 AM to next 6 AM. The bladder should be emptied when the collection is started (6 AM), and this urine is discarded. Thereafter all the urine should be collected. The next day urine is voided at 6 AM, and this sample is also collected.

**Urine preservatives**

The preservatives are used (1) to reduce bacterial action, (2) to minimize chemical decomposition, and (3) to decrease atmospheric oxidation of unstable compounds. The most satisfactory form of preservation of urine specimen is to refrigerate it during the collection. Formalin, thymol, chloroform, toluene, concentrated HCl and glacial acetic acid are the commonly used urine preservatives.

**QUALITY CONTROL (QC)**

Quality control should become an integral part of the operation of a clinical chemistry laboratory. The purpose of quality control is to ensure the reliability of each measurement performed on a sample. Quality is defined as conformance to satisfying the needs and expectations of the customers.

The term **error** should be discriminated from mistake in laboratory practice. A **mistake** is an avoidable error. Therefore, quality management programs aim at totally avoiding mistakes. However, in spite of all efforts we can only minimize errors. Errors can occur at different levels; physicians’ request, patient related, specimen related, test related and result related. If the errors are promptly detected, corrective action can be taken. In most cases the errors creep in due to pre- and postanalytical variables.

A central reference laboratory sends a serum sample containing known quantity of a substance; this is analyzed in a peripheral (small) laboratory. If the result obtained in the peripheral lab is the same as that of the reference laboratory, the arrangements available in the peripheral lab are said to be reliable. This is called **external quality control**. This type of checking is usually done once or twice in a month. Moreover, the peripheral laboratory itself makes a reference standard serum sample, and checks the results on the daily basis; this is called **internal quality control**.

Accuracy
It is the closeness of a result to the true value. For example, if one technician performs a test on a serum which is known to contain 100 mg/dl glucose and obtains a result of 99 mg/dl. A second technician does the same test on the same sample, and gets the result of 95 mg/dl. Then the value of the first technician is considered as accurate. Values farther away from the true value are less accurate than those closer.

Precision
This refers to the reproducibility of the result. If one technician performs glucose analysis on the same sample on three different occasions and obtains 100 mg/dl, 99 mg/dl and 101 mg/dl respectively, the results have been reproduced very well, and the precision is very good. Precision depends on the technique, the reagents, as well as on the technical ability of the technician.

Specificity
Specificity of a reaction denotes that only one substance will answer that particular test. For example, in the case of glucose oxidase method, only glucose molecules are assayed. So it is a very specific method. But if the reducing property of the glucose is utilized for the assay purpose (e.g. Nelson Somogyi method), other reducing agents in the blood will interfere in the reaction, and hence specificity is lowered. Specificity is determined by the method of the analysis.

Sensitivity
It indicates that whether the method could be utilized to test a very dilute solution. For example, biuret method is used for solutions having a few g of protein/dl. Spectrophotometric method is useful to detect a few mg of protein/dl, while ELISA method is employed if the solution has only microgram of protein/dl. Thus ELISA method is most sensitive.

Sensitivity and Specificity
The sensitivity of an assay is the fraction of those with a disease that the assay correctly predicts. Specificity is the fraction of those without the disease that the assay correctly predicts. A test should be both sensitive and specific. Generally speaking, as the sensitivity is increased, specificity is decreased.

Decision cut off limits for estimates of specificity and sensitivity are fixed by **receiver operating characteristic (ROC) curves** where sensitivity is plotted on the y-axis and specificity on the x-axis. False positives are plotted on the x-axis and true positive on the y-axis. The whole curve is the graphical display of the test performance. The ROC curves of two different tests can be compared more scientifically and the area under the curve is a measure of the relative performance. A test with high sensitivity and specificity is chosen.

The **odds ratio** is defined as the probability of the presence of a specific disease divided by the probability of its absence. The odds ratio reflects the prevalence of the disease in a population. Likelihood ratio is the probability of occurrence of a specific result divided by the probability of the same result if the disease were absent, i.e. sensitivity/1-specificity. Odds ratio of the occurrence of a disease is calculated before the test result and after the test result is known. This is then combined with likelihood ratio. The final result can be converted into probability.

Odds ratio after = odds ratio before x likelihood ratio

**Total Quality Management (TQM)**
Practices of TQM were introduced in the health care sector just as in industry. Similarly the six sigma principles and metrics (six standard deviation of process variation) of TQM were introduced in laboratory testing process. The 5 Qs in Quality management are: Quality planning, Quality laboratory process; Quality control; Quality assurance and Quality improvement. In order to implement a Quality assurance program in the laboratory, there should be commitment, resources and technical competence. The term Quality control refers to the technical procedures employed in quality assurance program. These include control of pre-analytical variables, analytical variables and monitoring the quality of analysis.

**Reference Materials and Calibration**
**Reference material (RM)** is a substance having homogenous and well established property values used for the calibration of an apparatus, an assay method, or assigning values to materials.

**Certified reference material (CRM):** The reference material is accompanied by a certificate, one or more of the property values having been certified by an established procedure.

**Calibration material or calibrator:** A material (device) of known or assigned qualitative and/or quantitative characteristics (like concentration, activity, intensity, reactivity) used to calibrate, graduate or adjust a measurement procedure or to compare the response obtained with the response of a test specimen.

**Control material** is a device, solution, lyophilized material or pooled specimen or artificially derived material to be used in quality control process. The use of reference materials, calibrators and controls will help a routine method to be correlated to a reference method when evaluated. The reference method itself is validated against a definitive method using primary reference material (PRM). True value is thus obtained. Both internal and external quality controls are required to validate a method.
Quality Control Charts
These are used to compare the observed control values with the control limits and provide a visual display which can be quickly reviewed. A daily QC chart should be available in the laboratory. The control chart helps to detect accuracy problems (shift in mean) and precision problem (shift in SD). The values will indicate if the analytical run is in control (acceptable) or out of control (unacceptable). If any of these changes are noticed, prompt action is warranted.

Inherent random errors can occur. It is very difficult to totally eradicate this error. But the control procedure should be able to detect an additional error signal in the presence of inherent random error (noise). Probability for false rejection and probability for error detection are denoted by power function graphs plotted using error on the y-axis and probability on the x-axis.

Levy Jening's (LJ) chart: Control specimens are analyzed during each run and the value plotted on the chart. When control values are within the control limits (+ or – 3 SD), patient’s values can be reported. Even if a single control value is out of limit, reporting should be stopped. Resolve the problem, repeat the entire run of specimen and controls.

Westergard's multirule chart: This uses the same procedure using 2 different controls, but the control limits show 1s, 2s and 3s values. When both control values are within 2s, the values are acceptable. If a single value exceeds plus or minus 2s, it is to be taken as a warning. If one value exceeds plus or minus 3s, random error is detected as per rejection rule. Two observations beyond plus or minus 2s also is a rejection rule sensitive to systematic error. If 4 values exceed plus or minus 1s, it indicates systematic error. This chart, therefore, helps to detect the type of error also. If the values are out of control, reporting should be stopped. In each case carefully examine which control rule is violated and act accordingly.

Single control charts display the difference between observed value and the expected mean. Cumulative sum (Cusum) chart is more quantitative. Calculate the difference between the value and the expected mean. Obtain the cusum by adding this difference to the cumulative sum of the previous difference. Cusum control chart is plotted and observe the slope.

A steep slope indicates a systematic error and the run is out of control. An alternative way of interpreting the cusum chart is to use the numerical limit of the cusum chart value itself.

External Quality Assessment Schemes (EQAS)
This compares the performance of different laboratories. Internal QC maintains the accuracy and precision of the analytical method, whereas EQAs are necessary for maintaining long-term accuracy of analytical methods. The basic program involves the analysis of the same QC material by different laboratories and the results are dispatched to the central control lab, for data analysis. Summary of reports are then sent to the participating laboratories by the controlling lab. For each analyte the SDI (Standard Deviation Index) is calculated using the student “t” test. When the difference is significant from a particular lab, that laboratory is alerted.

SDI = Lab Result – Group Mean/Groups SD

By analyzing two different control materials by each laboratory, the systematic error can be obtained by Youden plots (observed mean for material A on the y-axis versus observed mean for material B on the x-axis). The point for the laboratory is expected to fall at the center of the plot. If points fall away from the center, but on the same spot, it shows that the error is constant. By using appropriate software, laboratories can integrate internal and external quality assurance programs.

Other Clinical Biochemistry Topics
The basic principles of methods for analysing different constituents in clinical laboratory are given under appropriate headings, e.g. serum proteins (Chapter 4), serum enzymes (Chapter 23), blood sugar estimation (Chapter 24), serum cholesterol (Chapter 25), serum creatinine (Chapter 27), urinary VMA (Chapter 17), blood urea (Chapter 27), urine analysis (Chapter 27), renal clearance tests (Chapter 27). Normal reference values are given in the Appendix No. II.
CHAPTER 33

Fat Soluble Vitamins (A, D, E, K)

CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:

1. Vitamin A
2. Wald's visual cycle
3. Deficiency of vitamin A
4. Vitamin D
5. Deficiency of vitamin D
6. Vitamin E
7. Vitamin K

Vitamins may be defined as organic compounds occurring in small quantities in different natural foods and necessary for growth and maintenance of good health in human beings and in experimental animals. Vitamins are essential food factors, which are required for the proper utilization of the proximate principles of food like carbohydrates, lipids and proteins.

Discovery of vitamins started from observation of deficiency manifestations, e.g. scurvy, rickets, beriberi, etc. The vitamin theory was suggested by Hopkins in 1912 (Nobel Prize, 1929). The term "vitamine" was coined from the words vital + amine, since the earlier identified ones had amino groups. Later work showed that most of them did not contain amino groups, so the last letter 'e' was dropped in the modern term of vitamin.

Although vitamins are important nutritionally, their role has been over-emphasized in clinical practice. They are useful to correct deficiencies. But taking higher doses of vitamins will not boost up the health. All the vitamins are usually available in an ordinary Indian diet.

The vitamins are mainly classified into two:

1. The fat soluble vitamins are A, D, E and K
2. Water soluble vitamins are named as B complex and C. The major differences between these two groups of vitamins are given in Table 33.1.

*Vitamin B12 is an exception.

In general, deficiency of vitamins may occur due to:

a. reduced intake
b. impaired absorption
c. impaired metabolism
d. additional requirements
e. increased losses.

VITAMIN A

Chemistry

i. Vitamin A is fat soluble. The active form is present only in animal tissues.
ii. The pro-vitamin, beta-carotene is present in plant tissues. Beta carotene has two beta ionone rings connected by a polyisoprenoid chain
One molecule of beta carotene can theoretically give rise to two molecules of vitamin A; but it may produce only one in biological systems.

iii. All the compounds with vitamin A activity are referred to as retinoids. They are polyisoprenoid compounds having a beta-ionone ring system.

iv. Three different compounds with vitamin A activity are retinol (vitamin A alcohol), retinal (vitamin A aldehyde) and retinoic acid (vitamin A acid) (Fig. 33.1).

v. The retinal may be reduced to retinol by retinal reductase. This reaction is readily reversible. Retinal is oxidized to retinoic acid, which cannot be converted back to the other forms (Fig. 33.2).

vi. The side chain contains alternate double bonds, and hence many isomers are possible. The all-trans variety of retinal, also called vitamin A1 is most common (Fig. 33.1). Vitamin A2 is found in fish oils and has an extra double bond in the ring. Biologically important compound is 11-cis-retinal.

Absorption of Vitamin A

i. Beta carotene is cleaved by a di-oxygenase, to form retinal. The retinal is reduced to retinol by an NADH or NADPH dependent retinal reductase present in the intestinal mucosa. Intestine is the major site of absorption (Fig. 33.3).

ii. The absorption is along with other fats and requires bile salts. In biliary tract obstruction and steatorrhoea, vitamin A absorption is reduced.

iii. Within the mucosal cell, the retinol is re-esterified with fatty acids, incorporated into chylomicrons and transported to liver. In the liver stellate cells, vitamin is stored as retinol palmitate.

Transport from Liver to Tissues

The vitamin A from liver is transported to peripheral tissues as trans-retinol by the retinol binding protein or RBP (Table 28.1 and Fig. 33.3). One molecule of RBP binds one molecule of retinol. In the case of vitamin A deficiency, the RBP level in blood falls.

Uptake by Tissues

The retinol-RBP complex binds to specific receptors on the retina, skin, gonads and other tissues. The RBP does not enter in the cell. Inside the cytoplasm of cells, vitamin binds to cellular retinoic acid binding protein (CRBP) and finally to hormone responsive
elements (HRE) of DNA. Thus, genes are activated (Fig. 33.3).

Biochemical Role of Vitamin A
1. Wald’s Visual Cycle
   A. Generation of Nerve Impulse
      i. Wald was awarded Nobel Prize in 1967, for identifying the role of vitamin A in vision. Rhodopsin (mol. wt. 35,000 Daltons) plays the pivotal role in vision. It is a membrane protein found in the photoreceptor cells of the retina. Rhodopsin is made up of the protein opsin and 11-cis-retinal.
      ii. When light falls on the retina, the 11-cis-retinal isomerizes to all-trans-retinal (Fig. 33.4). A single photon can excite the rod cell. The photon produces immediate conformational change. The unstable intermediates produced are: Rhodopsin → Batho-rhodopsin → Lumirhodopsin → Metarhodopsin-I → Metarhodopsin-II → and finally Opsin + all-trans-retinal. Each of these intermediaries has a lifespan of only few picosecond to microseconds.
      iii. Visual pigments are G-protein-coupled receptors and 11-cis-retinal locks the receptor protein (opsin) in its inactive form (Fig. 33.5A). The isomerization and photo-excitation leads to activation of G-protein and generation of cyclic-GMP (Fig. 33.5B). Cyclic GMP acts as the gate for cation specific channels. Transducin is the G-protein in retina. The nerve impulse thus generated in the retina is transmitted to visual centres in the brain. The signal is terminated by phosphorylation of a serine residue of activated rhodopsin, by an enzyme rhodopsin kinase, so that the inhibitory protein beta-arrestin can bind and inactivate rhodopsin.

Fig. 33.4. Wald’s visual cycle. Blue color represents reactions in photoreceptor matrix. Green background represents reactions in retinal pigment epithelium. Red depicts blood. Yellow shows reactions in liver

Fig. 33.5A. Structure of retina showing rods and cones. The inset on right side shows the structural alteration during photoisomerization

The all-trans-retinal is then released from the protein.

Fig. 33.5B. Photoexcitation leads to activation of G-protein
B. Regeneration of 11-cis-retinal
   i. After dissociation, opsin remains in retina; but trans-retinal enters the blood circulation (Fig. 33.4). Later cis-retinal is generated, reaches retina. The re-attachment of 11-cis retinal to opsin is critical for shutting off the pigment’s catalytic activity.
   ii. The all-trans-retinal is isomerized to 11-cis-retinal in the retina itself in the dark by the enzyme retinal isomerase. This reaction is taking place in retinal pigment epithelium. The 11-cis retinal can recombine with opsin to regenerate rhodopsin.
   iii. Alternatively, all-trans-retinal is transported to liver and then reduced to all-trans-retinol by alcohol dehydrogenase (ADH), an NADH dependent enzyme. ADH contains zinc, and therefore, zinc is important in retinol metabolism. The all-trans-retinol is isomerized to 11-cis-retinol and then oxidised to 11-cis-retinal in liver. This is then transported to retina. This completes the Wald’s visual cycle (Fig. 33.4).

2. Dark Adaptation Mechanism
For his work on dark adaptation, Torsten Wiesel was awarded Nobel prize in 1981. Rods and Cones are diagrammatically represented in Figure 33.5A.
   i. Bright light depletes stores of rhodopsin in rods. Therefore when a person shifts suddenly from bright light to a dimly lit area, there is difficulty in seeing, for example, entering a cinema theater. After a few minutes, rhodopsin is resynthesized and vision is improved. This period is called dark adaptation time.
   ii. It is increased in vitamin A deficiency. Red light bleaches rhodopsin to a lesser extent; so doctors use red glasses, during fluoroscopic X-ray examination of the patients.

3. Rods are for Vision in Dim Light
In the retina, there are two types of photosensitive cells, the rods and the cones. Rods are responsible for perception in dim light. Rhodopsin present in rods is made up of 11-cis-retinal + opsin. Deficiency of cis-retinal will lead to increase in dark adaptation time and night blindness. In humans, one eye contains about 120 million rods, each of which carries 120 million molecules of rhodopsin. The number of rods is more in cats, mice and owls.

4. Cones are for Color Vision
   i. Cones are responsible for vision in bright light as well as color vision. They contain the photosensitive protein, conopsin.
   ii. There are 3 types of cones, each is characterized by a different conopsin, that is maximally sensitive to either blue (cyanopsin), green (iodopsin) or red (porphyropsin).
   iii. In cone proteins also, 11-cis-retinal is the chromophore. Reduction in number of cones or the cone proteins, will lead to color blindness. One eye contains about 6 million cones.

Colors have Profound Influence in Life
About one-third of grey matter of the brain is involved in the processing of visual information. About 70% of information inputs to the brain are visual. The optimists view the world through “rose-colored” eyes. When sad, a person is in a “blue” mood. Saffron color has tranquilizing effect, especially in agitated persons. Even a brief display of saffron color produces measurable relaxation in muscles. Blue color, although makes one peaceful and content, increases the muscle tone. Mice living in red light are most active, while in green light, they are least active. Other than the actual color, the subtle shift in hue is more responsible to unlock automatic impulses. The effects of colors on human moods have applications in criminology, psychiatry, interior decoration, chromotherapy and Yoga.

5. Other Biochemical Functions of Vitamin A
   i. Retinoic acid has a role in the regulation of gene expression and differentiation of tissues. All-trans-retinoic acid and 9-cis-retinoic acid act like steroid hormones. They bind to nuclear receptors; retinoic acid along with the receptor binds to the response elements of DNA. Retinoic acid receptors (RAR) bind all-trans-retinoic acid, while retinoic x receptors (RXR) bind to 9-cis-retinoic acid. RXRs form dimers with vitamin D-receptor also. This explains why deficiency of vitamin A impairs vitamin D function; when there is lack of 9-cis-retinoic acid to form...
receptor dimers, vitamin D function is not optimal.

ii. Retinol is necessary for the reproductive system. Retinol acts like a steroid hormone in controlling the expression of certain genes. This may account for the requirement of vitamin A for normal reproduction. In vitamin deficiency, miscarriages are noticed in female rats while atrophy of germinal epithelium and sterility are seen in male rats.

iii. Anti-oxidant property: There is a correlation between the occurrence of epithelial cancers and vitamin A deficiency. The anticancer activity has been attributed to the natural anti-oxidant property of carotenoids. Fresh vegetables containing carotenoids were shown to reduce the incidence of cancer.

iv. Beta carotenes may be useful in preventing heart attacks. Those who were given beta carotene supplements suffered half as many heart attacks as in the group taking placebo.

v. Vitamin A is necessary for the maintenance of normal epithelium and skin.

Deficiency manifestations of Vitamin A

1. Night Blindness or Nyctalopia
Visual acuity is diminished in dim light. The patient cannot read or drive a car in poor light. The dark adaptation time is increased.

2. Xerophthalmia
The conjunctiva becomes dry, thick and wrinkled. The conjunctiva gets keratinized and loses its normal transparency. Dryness spreads to cornea. It becomes glazy and lusterless due to keratinization of corneal epithelium. Infections may supercede.

3. Bitot’s Spots
These are seen as greyish-white triangular plaques firmly adherent to the conjunctiva. This is due to increased thickness of the conjunctiva in certain areas. All the ocular changes mentioned so far are completely reversible when vitamin is supplemented.

4. Keratomalacia
When the xerophthalmia persists for a long time, it progresses to keratomalacia (softening of the cornea). There is degeneration of corneal epithelium which may get vascularized. Later, corneal opacities develop (Fig. 33.6). Bacterial infection leads to corneal ulceration, perforation of cornea and total blindness.

5. Preventable Blindness
The deficiency of vitamin A is the most common cause of blindness in Indian children below the age of 5. One-third of the world’s blind population are residing in India. About 40% of blindness is preventable. Vitamin A deficiency is a major public health problem. A single dose of vitamin A is given, as a prophylactic measure, to children below 1 year age.

6. Skin and Mucous Membrane Lesions

i. Follicular hyperkeratosis or phrynoderma results from hyperkeratinization of the epithelium lining the follicles. The skin becomes rough. Keratinizing metaplasia of the epithelium of the respiratory, gastrointestinal and genitourinary tract have been observed. Epithelium is atrophied. Keratinization of urinary tract epithelium may lead to urinary calculi.

ii. The alterations in skin may cause increased occurrence of generalized infections. Therefore in old literature, vitamin A is referred to as anti-inflammatory vitamin.

iii. Isoretinone, a synthetic variant of vitamin A is known to reduce the sebaceous secretions, hence it is used to prevent acne formation during adolescence.

Acne is the most common disease of the skin. It affects 85% of teenagers, and 50% persons between the ages of 20 and 30 years. The role of hormones, particularly as a trigger of sebum production and sebaceous growth and differentiation, is well known. Excess production of androgens, GH, IGF-1, CRH and glucocorticoids, is associated with increased rates of acne. Acne may be a feature in many endocrine disorders, including polycystic ovary disease, Cushings syndrome, CAH, androgen-secreting tumors and acromegaly. Acne medicamentosa is the development of acne with the use of certain drugs, such as, testosterone, progesterone, lithium, phenytoin, isoniazid, and epidermal growth factor inhibitors.

Other General Manifestations
In vitamin A deficiency, growth retardation, especially failure of skeletal growth is noticed. This may be due to defective synthesis of chondroitin sulfate. Vitamin deficiency is also
manifested as decreased protein synthesis, lowered glycoprotein content of cell and reduced immunity against infections.

Causes for Vitamin A Deficiency
i. Decreased intake.
ii. Obstructive jaundice causing defective absorption.
iii. Cirrhosis of liver leading to reduced synthesis of RBP.
iv. Severe malnutrition, where amino acids are not available for RBP synthesis.
v. Chronic nephrosis, where RBP is excreted through urine.

Assessment of Deficiency
a. Dark adaptation test—It is the time required to adapt the eye to see objects in dim light. It is increased in vitamin A deficiency.
b. RBP (retinol-binding protein) level in serum is decreased. (See Table 28.1).
c. Vitamin A in serum is decreased. The colorimetric measurement is based on Carr and Price reaction, where retinoids are made to react with antimony trichloride to give a blue color. Vitamin A may be directly measured by spectrophotometry; it has maximum absorption at 325 nm.
d. Normal blood level of vitamin A is 25 to 50 microgram/dl.

Daily Requirement of Vitamin A
The recommended daily allowance (RDA) for
i. Children = 400-600 microg/day.
ii. Men = 750-1000 microg/day
iii. Women = 750 microg/day
iv. Pregnancy = 1000 microg/day
One international unit = 0.3 mg of retinol. One retinol equivalent = 1 microgram of retinol or 6 microgram of beta carotene.

Dietary Sources of Vitamin A
Animal sources include milk, butter, cream, cheese, egg yolk and liver. Fish liver oils (cod liver oil and shark liver oil) are very rich sources of the vitamin. Vegetable sources contain the yellow pigment beta carotene. Carrot contains significant quantity of beta carotene (Fig. 33.7). Papaya, mango, pumpkins and green leafy vegetables (spinach, amaranth) are other good sources for vitamin A activity. During cooking the activity is not destroyed.

Therapeutic use of Vitamin A
When deficiency of vitamin A is identified, supplementation is given as capsules or injection. Therapeutic dose is generally 20-50 times higher than the RDA. All-trans-retinoic acid is used as adjuvant in the treatment of promyelocytic leukemia. It causes remission due to its effect on differentiation of cells.

Hypervitaminosis A or Toxicity
Excessive intake can lead to toxicity since the vitamin is stored. It has been reported in children where parents have been overzealous in supplementing the vitamins. Eskimos refrain from eating the liver of polar bear due to its high vitamin A content. Symptoms of toxicity include anorexia, irritability, headache, peeling of skin, drowsiness and vomiting. Some of these signs are due to increased intracranial tension. Sometimes swelling over long bones (bony exostosis) may occur with painful bones. Enlargement of liver is also seen in children. Higher concentration of retinol increases lysosomal enzymes, leading to cellular death.

Hypercarotenemia can result from persistent excessive consumption of foods rich in carotenoids. The skin becomes yellow, but no staining of sclera as in jaundice is observed.

VITAMIN D (CHOLECALCIFEROL)
There are reports of symptoms of rickets from historians as early as 2nd century AD. Francis Glisson wrote a classical account of infantile rickets in 1650. Experimental rickets induced by dietary deficiency was produced in rats by McCollum in 1919. Angus and coworkers isolated vitamin D in 1931 and named it as calciferol, which was later identified as Vitamin D3. The structural elucidation was done independently by Otto Diels and Kurt Alder. Both were awarded Nobel prize in 1950.

Formation of Vitamin D
Vitamin D is derived either from 7-dehydrocholesterol or ergosterol by the action of ultraviolet radiations. 7-dehydrocholesterol, an intermediate of a minor pathway of cholesterol synthesis, is available in the Malpighian layer of epidermis. In the skin, ultraviolet light (290-315 nm) breaks the bond between position 9 and 10 of the steroid ring. So, the ring B is opened, to form the provitamin, secosterol (Fig. 33.8). The cis double bond between 5th and 6th carbon atoms, is then isomerized to a trans double bond (rotation on the 6th carbon atom) to give rise to vitamin D$_3$ or cholecalciferol (Fig. 33.8). So, vitamin D is called the “sun-shine vitamin”.

Skin is the largest organ in the body. It makes about 16% of body weight. It is kept nourished by a quarter of the body's
blood supply. It is the temperature regulator of the body. The production of vitamin D in the skin is directly proportional to the exposure to sunlight and inversely proportional to the pigmentation of skin. An increase in solar zenith angle during November to March shifts the wavelength of UV rays to longer wavelengths which will not produce the vitamin; hence vitamin deficiency is seen in winter. Excessive exposure to sunlight does not result in vitamin D toxicity since excess previtamin D3 and D3 are destroyed by sunlight itself.

Commercially the vitamin is derived from the fungus, ergot. The ergosterol when treated with ultraviolet light, ergocalciferol or vitamin D2 is produced. Ergocalciferol differs in having an unsaturation in the side chain and an extra methyl group (C28).

**Activation of Vitamin D**

i. Vitamin D is a prohormone. The cholecalciferol is first transported to liver, where hydroxylation at 25th position occurs, to form 25-hydroxy cholecalciferol (25-HCC). The hepatic 25-hydroxylase is a microsomal mono-oxygenase. It requires cytochrome P-450 and NADPH (Fig. 33.9). 25-HCC is the major storage form.

ii. In plasma, 25-HCC is bound to "vitamin D binding protein" (VDBP), an alpha-2 globulin.

iii. In the kidney, it is further hydroxylated at the 1st position. The 1-alpha hydroxylase is located in mitochondria of proximal convoluted tubules. It requires cytochrome P-450, NADPH and ferrodoxin (an iron-sulfur protein). Thus 1,25-dihydroxy cholecalciferol (DHCC) is generated. Since it contains three hydroxyl groups at 1, 3 and 25 positions, it is also called Calcitriol (Fig. 33.9). The calcitriol thus formed is the active form of vitamin; it is a hormone (See Box 33.1). 24,25-dihydroxy cholecalciferol may be formed by hydroxylation of 25-HCC at the 24th position.

**Box 33.1. Calcitriol and Calcitonin are Different**

**Calcitriol** is the physiological active form of vitamin D. It increases the blood calcium level. **Calcitonin** is the peptide hormone released from thyroid gland. It decreases the blood calcium.

**Biochemical Effects of Vitamin D**

The sites of action are:

a. intestinal villi cells
b. bone osteoblasts
c. kidney distal tubular cells.

**A. Vitamin D and Absorption of Calcium**

Calcitriol promotes the absorption of calcium and phosphorus from the intestine. In the brush-border surface, calcium is absorbed passively. From the intestinal cell to blood, absorption of calcium needs energy. It is either by the sodium-calcium exchange mechanism or by pumping out the calcium-calbindin complex. Calcitriol acts like a steroid hormone. It enters the target cell and binds to a cytoplasmic receptor. The hormone-receptor complex interacts with DNA and causes derepression and consequent transcription of specific genes that code for Calbindin (Fig. 33.10). Due to the increased availability of calcium binding protein, the absorption of calcium is increased.

**B. Effect of Vitamin D in Bone**

Mineralization of the bone is increased by increasing the activity of osteoblasts (Chapter 35). Calcitriol coordinates the remodelling action of osteoclasts and osteoblasts. It produces the differentiation of osteoclast precursors from multinucleated cells of osteoblast lineage. Calcitriol stimulates osteoblasts which secrete alkaline

---

**Fig. 33.8. Synthesis of cholecalciferol or vitamin D3**
phosphatase. Due to this enzyme, the local concentration of phosphate is increased. The ionic product of calcium and phosphorus increases, leading to mineralization.

C. Effect of Vitamin D in Renal Tubules
Calcitriol increases the reabsorption of calcium and phosphorus by renal tubules, therefore both minerals are conserved (PTH conserves only calcium) (Chapter 35).

D. Regulation of Calcitriol
The hormonal level of calcitriol is maintained by the feedback control. The rate of production is modulated by serum levels of calcium, phosphorus, PTH and calcitriol itself. The major site of control is on the 1-alpha-hydroxylase of kidney. Hypercalcemia decreases calcitriol. Low dietary calcium and hypocalcemia increase the rate of production of 1,25-DHCC. The stimulatory effect of hypocalcemia on 1-alpha-hydroxylase is through PTH. Hypercalcemia decreases calcitriol. The half-life of 1, 25-DHCC is 6-8 hours and is mainly excreted through the bile. The inactivation is by oxidation of the side chain. Hydroxylation at the 24th position by the kidney also lowers the activity. Vitamin D deficient state (low calcium and phosphate) will enhance the action of 1-alpha hydroxylase. When vitamin D status is adequate, or calcium level is high, 24-hydroxylation is favored, forming 24,25-DHCC, which is less active. 1,25-DHCC level directly regulates PTH secretion.

Deficiency of Vitamin D
The deficiency diseases are rickets in children and osteomalacia in adults. Hence vitamin D is known as antirachitic vitamin.

A. Causes for Vitamin D Deficiency
i. Deficiency of vitamin D can occur in people who are not exposed to sunlight properly, e.g. inhabitants of northern latitudes, in winter months, in people who are bedridden for long periods, or those who cover the whole body (purdah).

ii. Nutritional deficiency of calcium or phosphate may also produce similar clinical picture.

iii. Malabsorption of vitamin (obstructive jaundice and steatorrhea). High phytate content in diet may also reduce the absorption of vitamin.

iv. Abnormality of vitamin D activation. Liver and renal diseases may retard the hydroxylation reactions.

v. Deficient renal absorption of phosphates.

B. Clinical Features of Rickets
i. Rickets is seen in children. There is insufficient mineralization of bone. Bones become soft and pliable. The bone growth is markedly affected.

ii. Plasma calcium and phosphorus are low normal with alkaline phosphatase (bone isoenzyme) being markedly elevated.
iii. **Vitamin D resistant** rickets is found to be associated with *Fanconi syndrome*, where the renal tubular reabsorption of bicarbonate, phosphate, glucose and amino acids are also deficient.

iv. **Renal rickets**: In kidney diseases, even if vitamin D is available, calcitriol is not synthesized. These cases will respond to administration of calcitriol.

v. **End organ refractoriness** to 1,25-DHCC will also lead to rickets. Either a decrease in the number of cytosolic receptor or a structurally abnormal receptor is noticed. The bone disease has been found to respond to megadoses of calcitriol (35 mg/day).

Other Actions of Vitamin D
Recent research has proved that most tissues possess vitamin D receptor and several tissues have the enzymes to generate calcitriol. 1,25-DHCC has been found to have a modulatory effect on immunohematopoietic system. Therapeutic doses given to children with rickets have been found to correct the anemia, hypocellularity of the bone marrow and increased susceptibility to infection. It has also been found to reduce the risk of cancer and coronary vascular disease. Beneficial effects have been observed in patients with AIDS.

**Requirement of Vitamin D**

i. Children = 10 microgram (400 IU)/day

ii. Adults = 5 microgram (200 IU)/day

iii. Pregnancy, lactation = 10 microgram/day

iv. Above the age of 60 = 600 IU per day.

**Sources of Vitamin D**

Exposure to sunlight produces cholecalciferol. Moreover fish liver oil, fish and egg yolk are good sources of the vitamin. Milk contains moderate quantity of the vitamin.

**Hypervitaminosis D**

Doses above 1500 units per day for very long periods may cause toxicity. Symptoms include weakness, polyuria, intense thirst, difficulty in speaking, hypertension and weight loss. Hypercalcemia leads to calcification of soft tissues, (metastatic calcification, otherwise called calcinosis), especially in vascular and renal tissues. Although vitamin D is toxic in higher doses, excessive exposure to sunlight does not result in vitamin D toxicity, because excess D₃ is destroyed by sunlight itself.
VITAMIN E

The active vitamin was isolated from wheat germ oil and named tocopherol (tokos = child birth; pheros = to bear; al = alcohol). Initial studies of induced vitamin E deficiency in laboratory animals resulted in infertility and therefore the vitamin came to be known as anti-infertility vitamin. Now vitamin E is known as the most potent biological antioxidant.

Chemical Nature
A chromane ring (tocol) system, with an isoprenoid side chain is present in all the eight naturally occurring tocopherols. Of these, alpha tocopherol (5, 7, 8-trimethyl tocol) has greatest biological activity (Fig. 33.12). The structure of vitamin E was elucidated by Paul Karrer, who was awarded Nobel prize in 1937.

Metabolism of Vitamin E
Normal blood level of tocopherol is 0.5-1 mg/dl. It is absorbed along with other fats and needs the help of bile salts. Tocopherol is absorbed and transported as chylomicrons. It is stored in adipose tissue. During catabolism, the chromane ring and side chain may be oxidized and excreted in bile after conjugation with glucuronic acid.

Biochemical Role of Vitamin E

i. Vitamin E is the most powerful natural antioxidant (Chapter 20). Free radicals are continuously being generated in living systems. Their prompt inactivation is of great importance. Vitamin E is a known biological antioxidant able to quench the lipid peroxidation chain and to protect the plasma membranes from the attack of free radicals.

ii. The free radicals would attack bio-membranes. Vitamin E protects RBC from hemolysis. By preventing the peroxidation, it keeps the structural and functional integrity of all cells.

iii. Gradual deterioration of ageing process is due to the cumulative effects of free radicals. Vitamin E also boosts immune response.

iv. It reduces the risk of atherosclerosis by reducing oxidation of LDL (Fig. 33.13; see Chapter 25 for Atherosclerosis).

v. Vitamin E can depress leukocyte oxidative bactericidal activity.

Inter-relationship with Selenium
Selenium is present in glutathione peroxidase; an important enzyme that oxidizes and destroys the free radicals (Chapter 20). Selenium has been found to decrease the requirement of vitamin E and vice versa. They act synergistically to minimize lipid peroxidation. Selenium is described in Chapter 35.

Deficiency Manifestations of Vitamin E
In rats, inability to produce healthy ovum and loss of motility of spermatozoa, hemolysis of red cells, acute hepatic necrosis and muscular dystrophy are observed. In a normal adult, the body vitamin E stores can meet the requirement for several months.

Human deficiency has not been reported. But in volunteers, vitamin E deficiency has been shown to produce increased fragility of RBCs, muscular weakness and creatinuria.

Recommended Daily Allowance
Males 10 mg per day
Females 8 mg/day
Pregnancy 10 mg/day
Lactation 12 mg/day.

15 mg of vitamin E is equivalent to 33 international units. The requirement increases with higher intake of PUFA. Pharmacological dose is 200-400 IU per day.

Sources of Vitamin E
Vegetable oils are rich sources of vitamin E; e.g. wheat germ oil, sunflower oil, safflower oil, cotton seed oil, etc. Fish liver oils are devoid of vitamin E.
Chapter 33; Fat Soluble Vitamins (A, D, E, K)  □  389

Absorption and Storage
Absorption of vitamin K occurs in the intestine along with chylomicrons. Bile salts are required for the normal absorption. The vitamin K may be derived from the diet or intestinal bacterial synthesis. It is stored in the liver and transported in plasma along with beta lipoproteins.

Biochemical Role of Vitamin K
a. Vitamin K is necessary for coagulation. Factors dependent on vitamin K are Factor II (prothrombin); Factor VII (SPCA); Factor IX (Christmas factor); Factor X (Stuart Prower factor)
b. All these factors are synthesized by the liver as inactive zymogens. They undergo post-translational modification; gamma carboxylation of glutamic acid residues. These are the binding sites for calcium ions. The gamma carboxy glutamic acid (GCG) synthesis requires vitamin K as a co-factor (Fig. 33.16).
c. Vitamin K dependent gamma carboxylation is also necessary for the functional activity of osteocalcin as well as structural proteins of kidney, lung and spleen. Osteocalcin is synthesized by osteoblasts and seen only in bone. It is a small protein (40-50 amino acids length) that binds tightly to hydroxyapatite crystals of bone. This binding is dependent on the degree of gamma carboxylation. Osteocalcin also contains hydroxyproline, so it is dependent on both vitamins K and C. Moreover, vitamin D induces its synthesis.

7. Hypervitaminosis E
At doses above 1000 IU per day, it may cause tendency to hemorrhage, as it is a mild anticoagulant.

VITAMIN K

Chemistry of Vitamin K
The letter "K" is the abbreviation of the German word "koagulation vitamin". They are naphthoquinone derivatives, with a long isoprenoid side chain. The length of side chain will differ. Vitamin K₁ has 20C side chain (phyloquinone) (Fig. 33.15). Vitamin K₂ has a 30C side chain. Yet another structurally similar synthetic compound having vitamin K activity is Menadione. It is water soluble synthetic vitamin, widely used in clinical practice. Henrik Dam isolated vitamin K₁ in 1929, while Edward Doisy isolated vitamin K₂ in 1939. Both of them were awarded Nobel prize in 1943.

Fig. 33.14. Vitamin K cycle. Dicoumarol, a structural analogue inhibits vitamin K reductase

Fig. 33.15. Vitamin K

Fig. 33.16. Vitamin K as co-factor in GCG synthesis
Vitamin K Dependent Carboxylase
It is microsomal enzyme. It requires oxygen, CO$_2$, NADPH and reduced vitamin K. In this process, the vitamin passes through a cycle (Fig. 33.14). This process is competitively inhibited by warfarin and dicoumarol.

Causes for Deficiency of Vitamin K
In normal adults dietary deficiency seldom occurs since the intestinal bacterial synthesis is sufficient to meet the needs of the body. However deficiency can occur in conditions of malabsorption of lipids. This can result from obstructive jaundice, chronic pancreatitis, sprue, etc. Prolonged antibiotic therapy and gastrointestinal infections with diarrhoea will destroy the bacterial flora and can also lead to vitamin K deficiency.

Clinical Manifestations of Deficiency
i. Hemorrhagic disease of the newborn is attributed to vitamin K deficiency. The newborns, especially the premature infants have relative vitamin K deficiency. This is due to lack of hepatic stores, limited oral intake (breast milk has very low levels, 15 mg/liter) and absence of intestinal bacterial flora.

ii. It is often advised that pre-term infants be given prophylactic doses of vitamin K (1 mg Menadione).

iii. In children and adults, Vitamin K deficiency may be manifested as bruising tendency, ecchymotic patches, mucous membrane hemorrhage, post-traumatic bleeding and internal bleeding.

iv. Prolongation of prothrombin time and delayed clotting time are characteristic of vitamin K deficiency.

v. Measurement of prothrombin time (PT) is taken as an index of liver function. When liver function is considerably lowered, prolongation of PT occurs due to deficient synthesis of the coagulation factors. In such cases, administration of vitamin fails to restore PT to normal levels. Hence before undertaking any surgery on jaundiced patients, PT before and after administration of vitamin K should be done.

vi. Warfarin and dicoumarol will competitively inhibit the gamma carboxylation system due to structural similarity with vitamin K. Hence they are widely used as anticoagulants for therapeutic purposes.

vii. Treatment of pregnant women with warfarin can lead to fetal bone abnormalities (fetal warfarin syndrome).

Daily Requirement of Vitamin K
Recommended daily allowance is 50-100 mg/day. This is usually available in a normal diet.

Sources of Vitamin K
Green leafy vegetables are good dietary sources. Even if the diet does not contain the vitamin, intestinal bacterial synthesis will meet the daily requirements, as long as absorption is normal.

Hypervitaminosis K
Hemolysis, hyperbilirubinemia, kernicterus and brain damage are the manifestations of toxicity. Administration of large quantities of menadione may result in toxicity. This should be kept in mind in treating premature babies.
CHAPTER 34

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Thiamine (Vitamin B1)
2. Riboflavin (Vitamin B2) and FAD
3. Niacin, NAD⁺ and NADP⁺
4. Pyridoxine (Vitamin B6)
5. Pantothenic acid and Co-enzyme A
6. Biotin
7. Folic acid
8. Vitamin B₁₂
9. Ascorbic acid (Vitamin C)

B COMPLEX GROUP OF VITAMINS
These vitamins are chemically not related to one another. They are grouped together because all of them function in the cells as co-enzymes. The important members of vitamin B complex group are enumerated as 1 to 8 above. In old literature, a few more members such as Choline, Inositol, Lipoic acid and para amino benzoic acid (PABA) are also included in this group. Although they have important functions inside the body, they cannot be considered as vitamins, because they are available in plenty. PABA is not a vitamin for higher species, but it is required by bacteria for synthesis of folic acid.

THIAMINE (VITAMIN B₁)
Thiamine is also called as vitamin B₁ (Box 34.1). In old literature, it is designated as Aneurine (it can relieve neuritis) or antiberiberi factor. In 1900, Christian Eijkman produced beriberi in chicken by feeding polished rice (Nobel Prize, 1929). Adolf Windaus (Nobel prize, 1928) elucidated the structure of the vitamin.

Sources
Aleurone layer of cereals (food grains) is a rich source of thiamine. Therefore whole wheat flour and unpolished hand-pound rice have better nutritive value than completely polished refined foods. When the grains are polished, aleurone layer is usually removed. Yeast is also a very good source. Thiamine is partially destroyed by heat.

Water Soluble Vitamins
(Thiamine, Riboflavin, Niacin, Pyridoxine, Pantothenic acid, Biotin, Folic acid, Vitamin B₁₂ and Ascorbic acid)

Box 34.1. Thiamine and Thymine are Different
THYMOINE is the base present in DNA
THIAMINE is the vitamin B₁

Structure of Thiamine
Thiamine contains a substituted pyrimidine ring connected to a substituted thiazole ring by means of methylene bridge. The vitamin is then converted to its active co-enzyme form by addition of two phosphate groups, with the help of ATP (Fig. 34.1). It is catalyzed by thiamine pyrophosphotransferase.

Physiological Role of Thiamine
i. Pyruvate dehydrogenase: The co-enzyme form is thiamine pyrophosphate (TPP). It is used in oxidative decarboxylation of alpha keto acids, e.g. pyruvate dehydrogenase catalyzes the breakdown of pyruvate, to acetyl CoA and carbon dioxide (see Fig. 9.22).

Fig. 34.1. Structure of thiamine pyrophosphate
ii. **Alpha ketoglutarate dehydrogenase**: An analogous biochemical reaction that requires TPP is the oxidative decarboxylation of alpha ketoglutarate to succiny1 CoA and CO₂ (See citric acid cycle, Fig. 18.2).

iii. **Transketolase**: The second group of enzymes that use TPP as co-enzyme are the transketolases, in the hexose monophosphate shunt pathway of glucose (Fig. 10.3).

iv. The main role of thiamine (TPP) is in carbohydrate metabolism. So, the requirement of thiamine is increased along with higher intake of carbohydrates.

### Deficiency Manifestations of Thiamine

A. **Beriberi**: Deficiency of thiamine leads to beriberi. It is a Singhalese word, meaning "weakness". The early symptoms are anorexia, dyspepsia, heaviness and weakness. Subjects feel weak and get easily exhausted.

B. **Wet beriberi**: Here cardiovascular manifestations are prominent. Edema of legs, face, trunk and serous cavities are the main features. Palpitation, breathlessness and distended neck veins are observed. Death occurs due to heart failure.

C. **Dry beriberi**: In this condition, CNS manifestations are the major features. Walking becomes difficult. Peripheral neuritis with sensory disturbance leads to complete paralysis.

D. **Infantile beriberi**: It occurs in infants born to mothers suffering from thiamine deficiency. Restlessness and sleeplessness are observed.

E. **Wernicke-Korsakoff syndrome**: It is also called as cerebral beriberi. Carl Wernicke in 1894 and Sergiei Sergievich Korsakoff in 1887 described the condition. Clinical features are those of encephalopathy (ophthalmoplegia, nystagmus, cerebellar ataxia) plus psychosis. It is seen only when the nutritional status is severely affected.

F. **Polyneuritis**: It is common in chronic alcoholics. Alcohol utilization needs large doses of thiamine. Alcohol inhibits intestinal absorption of thiamine, leading to thiamine deficiency. Polyneuritis may also be associated with pregnancy and old age.

Such thiamine deficiency in alcoholism may cause impairment of conversion of pyruvate to acetyl CoA. This results in increased plasma concentration of pyruvate and lactate, leading to lactic acidosis.

### Biochemical Parameters

In thiamine deficiency, blood thiamine is reduced, but pyruvate, alpha ketoglutarate and lactate are increased. Erythrocyte transketolase activity is reduced; this is the earliest manifestation seen even before clinical disturbances.

### Recommended Daily Allowance of Thiamine

It depends on calorie intake (0.5 mg/1000 calories). Requirement is 1-1.5 mg/day. Thiamine is useful in the treatment of beriberi, alcoholic polyneuritis, neuritis of pregnancy and neuritis of old age.

**RIBOFLAVIN (VITAMIN B₂)**

Lactoflavin (milk), hepatoflavin (liver) and ovoflavin (eggs) are chemically identical to riboflavin. Riboflavin was the first B complex component to be isolated in a pure state. This vitamin is synthesized by green plants and micro-organisms. Warburg (Nobel prize 1931), isolated the "yellow enzyme" of cellular respiration. Later Axel Theorell (Nobel prize, 1955) isolated riboflavin. In 1935, Paul Karrer (Nobel prize, 1937) determined the structure.

**Structure of Riboflavin**

Riboflavin has a dimethyl isoalloxazine ring to which a ribitol is attached (Fig. 34.2). Ribitol is the alcohol of ribose sugar. Riboflavin is converted to its active co-enzyme forms (FMN and FAD) with the help of ATP (Fig. 34.4). Riboflavin is heat stable.

---

**Fig. 34.2. Riboflavin structure**
Co-enzyme Activity of Riboflavin

Riboflavin exists in tissues tightly bound (but not covalently) with enzymes. Enzymes containing riboflavin are called flavoproteins. The two coenzymes are FMN (flavin mononucleotide) and FAD (flavin adenine dinucleotide) (Fig. 34.4).

A. FAD Accepts Hydrogen

During the oxidation process, FAD accepts two hydrogen atoms from substrate. In turn, FAD is reduced to FADH$_2$. The two nitrogen atoms of isalloxazine nucleus accept the hydrogen atoms (Fig. 34.3).

B. FMN-dependent Enzymes

i. During the amino acid oxidation, FMN is oxidized. It is reoxidized by molecular oxygen to produce hydrogen peroxide (Fig. 14.10).

ii. In the respiratory chain, the NADH dehydrogenase contains FMN. The electrons are transported in the following manner (Chapter 19):

\[
\text{NAD}^+ \rightarrow \text{FMN} \rightarrow \text{CoQ}
\]

C. FAD-dependent Enzymes

These are enumerated in Box 34.2. FADH$_2$ when oxidized in the electron transport chain will generate 1 ½ ATP molecules (Chapter 19).

Riboflavin Deficiency

a. Causes: Natural deficiency of riboflavin in man is uncommon, because riboflavin is synthesized by the intestinal flora. Riboflavin deficiency usually accompanies other deficiency diseases such as beriberi, pellagra and kwashiorkor.

b. Manifestations: Symptoms are confined to skin and mucous membranes.

i. Glossitis (Greek, glossa = tongue).

ii. Magenta colored tongue

iii. Cheilosis (Greek, cheilos = lip)

Dietary Sources of Riboflavin

Rich sources are liver, dried yeast, egg and whole milk. Good sources are fish, whole cereals, legumes and green leafy vegetables.

Daily Requirement

Riboflavin is concerned mainly in the metabolism of carbohydrates and requirement is related to calorie intake. Adults on sedentary work require about 1.5 mg per day. During pregnancy, lactation and old age, additional 0.2 to 0.4 mg /day are required.

Box 34.2. FAD-dependent Enzymes

1. Succinate to fumarate by succinate dehydrogenase (Fig. 18.2, step 6).
2. Acyl CoA to alpha-beta unsaturated acyl CoA by acyl CoA dehydrogenase (Fig. 11.9, step 1).
3. Xanthine to uric acid by xanthine oxidase (see Fig. 39.15).
4. Pyruvate to acetyl CoA by pyruvate dehydrogenase (Fig. 9.22).
5. Alpha ketoglutarate to succinyl CoA by alpha ketoglutarate dehydrogenase (Fig. 18.2, step 4).
NIACIN

Niacin and Nicotinic acid are synonyms. It is also called as Pellagra preventing factor of Goldberger. The term nicotinic acid should not be confused with nicotine. Nicotinic acid is a vitamin; but, nicotine is the potent poison from tobacco. 

Nicotinamide is the active form of the vitamin, present in tissues. Warburg (Nobel prize, 1931) elucidated the structure of NAD+, and Alexander Todd (Nobel prize, 1957) demonstrated its function. It was originally named as co-enzyme-I, which was later designated as DPN (diphosphopyridine nucleotide), and finally in 1965 as NAD⁺.

Chemistry of Niacin

Niacin is pyridine-3-carboxylic acid. Nicotinamide is the acid amide (Fig. 34.5). In NAD⁺ or NADP⁺, the reactive site is the carbon atom 4 and the nitrogen atom of the nicotinamide ring. (See numbering in Fig. 39.6). The co-enzyme is bound to the apo-enzyme.

Co-enzyme Forms of Niacin

Niacin is converted to its co-enzyme forms, viz. Nicotinamide adenine dinucleotide (NAD⁺) and Nicotinamide adenine dinucleotide phosphate (NADP⁺). The niacin is attached to a ribose phosphate to form a mononucleotide. It is then attached to AMP, to form the dinucleotide (Fig. 34.6).

The nitrogen atom of niacinamide contains one positive charge. The structure is abbreviated as NAD⁺. (The +ve sign is always shown). In the case of NADP⁺, one more phosphoric acid is attached to the ribose of the AMP (see the asterisk in Fig. 34.6).

One Hydrogen Atom and One Electron

i. In the oxidized form, nitrogen of the nicotinamide residue has a positive charge. Hence the oxidized form of co-enzyme is usually written as NAD⁺.

ii. In the process of reduction, NAD⁺ accepts one hydrogen atom fully. The other hydrogen is ionized. Only the electron is accepted (Fig. 34.7). See the positive sign in the molecule is removed.

\[ 2H \rightarrow H^+ + e^- \]

Box 34.3. NAD⁺ Dependent Enzymes

1. Lactate dehydrogenase (lactate → pyruvate) (Fig. 9.14)
2. Glyceraldehyde-3-phosphate dehydrogenase (glyceraldehyde-3-phosphate → 1, 3-bisphosphoglycerate) (Fig. 9.10)
3. Pyruvate dehydrogenase (pyruvate → acetyl CoA) (Fig. 9.22)
4. Alpha ketoglutarate dehydrogenase (alpha ketoglutarate → succinyl CoA (Fig. 18.2)
5. Beta hydroxy acyl CoA dehydrogenase (beta hydroxy acyl CoA → beta keto acyl CoA (Step 3, Fig. 11.9)
6. Glutamate dehydrogenase (Glutamate → alpha keto glutarate) (Fig. 14.9)

Thus NAD⁺ accepts one H atom and one e⁻ (electron), to form NADH. The hydrogen ion (H⁺) is released into the surrounding medium. During the oxidation of NADH, the reaction is reversed (Fig. 34.7).

NAD⁺ Dependent Enzymes

They are so many, that an exhaustive listing is not attempted. A few examples are given in Box 34.3. One NADH molecule is oxidized in the respiratory chain to generate 2½ ATPs (See Chapter 19 for details). But NADPH is used almost exclusively for reductive biosynthetic reactions.

Fig. 34.6. Structure of NAD⁺ (In the case of NADP⁺ phosphoric acid residue is attached to the hydroxyl group marked with asterisk)
**NADPH Dependent Reactions**

NADPH generating reactions are shown in Box 34.4. A few examples of NADPH utilizing enzymes are shown in Box 34.5. Some enzymes can use either NAD+ or NADP+ as coenzyme, e.g. glutamate dehydrogenase.

In addition to this co-enzyme role, NAD+ is the source of ADP-ribose for the ADP-ribosylation of proteins and poly-ADP-ribosylation of nucleoproteins.

**Niacin Deficiency**

**A. Pellagra**

Deficiency of niacin leads to the clinical condition called pellagra. Pellagra is an Italian word, meaning "rough skin". Pellagra is caused by the deficiency of Tryptophan as well as Niacin. Pellagra is seen more in women; this may be because tryptophan metabolism is inhibited by estrogen metabolites. The symptoms of pellagra are:

i. **Dermatitis:** In early stages, bright red erythema occurs, especially in the feet, ankles and face (Fig. 34.8A). Increased pigmentation around the neck is known as Casal’s necklace. The dermatitis is precipitated by exposure to sunlight (Fig. 34.8B).

**Box 34.4. NADPH Generating Reactions**

1. Glucose-6-phosphate dehydrogenase in the hexose monophosphate shunt pathway (Glucose-6-phosphate → 6-phosphogluconolactone) (Fig. 10.1)
2. 6-phosphogluconate dehydrogenase in the shunt pathway (6-phosphogluconate → 3- keto-6-phosphogluconate) (Fig. 10.1)
3. Cytoplasmic isocitrate dehydrogenase
4. Malic enzyme (malate to pyruvate).

**Box 34.5. NADPH Utilizing Reactions**

1. Keto acyl ACP dehydrogenase (Beta keto acyl ACP → beta hydroxy acyl ACP) (Step 4, Fig.11.15)
2. Alpha, beta unsaturated acyl ACP → acyl ACP (Step 6, Fig.11.15)
3. HMG CoA reductase (HMG CoA → mevalonate) (Fig.12.2)
4. Met-hemoglobin → hemoglobin
5. Folate reductase (Folate → dihydrofolate → tetrahydrofolate) (Fig. 34.17)
6. Phenyl alanine hydroxylase (Phenylalanine → tyrosine) (Fig.17.1)

**i. Diarrhea:** The diarrhea may be mild or severe with blood and mucus. This may lead to weight loss. Nausea and vomiting may also be present.

**ii. Dementia:** It is frequently seen in chronic cases. Delerium is common in acute pellagra. Irritability, inability to concentrate and poor memory are more common in mild cases. Ataxia and spasticity are also seen.

**B. Niacin is Synthesized from Tryptophan**

For details see under tryptophan metabolism in Chapter 17. Quinolinate phosphoribosyl transferase is the rate limiting enzyme in the conversion of niacin to NAD+. About 60 mg of tryptophan is equivalent to 1 mg of niacin.

**C. Causes for Niacin Deficiency**

i. **Dietary deficiency of Tryptophan:** Pellagra is seen among people whose staple diet is maize (South and Central America). In maize, niacin is present; but it is in a bound form, and is unavailable. Pellagra is also seen when staple diet is sorghum (jowar or guinea corn) as in Central and Western India. Sorghum, contains leucine in high quantities. Leucine inhibits the QPRT enzyme, and so niacin
cannot be converted to NAD$^+$ (Leucine pellagra).

ii. **Deficient synthesis**: Kynureninase, an important enzyme in the pathway of tryptophan, is pyridoxal phosphate dependent. So conversion of tryptophan to niacin is not possible in pyridoxal deficiency.

iii. **Isoniazid (INH)**: It is an anti-tuberculous drug, which inhibits pyridoxal phosphate formation. Hence there is block in conversion of tryptophan to NAD$^+$.

iv. **Hartnup disease**: Tryptophan absorption from intestine is defective in this congenital disease. Moreover, tryptophan is excreted in urine in large quantities. This leads to lack of tryptophan and consequently deficiency of nicotinamide.

v. **Carcinoid syndrome**: The tumor utilizes major portion of available tryptophan for synthesis of serotonin; so tryptophan is unavailable.

### Dietary Sources of Niacin
The richest natural sources of niacin are dried yeast, rice polishing, liver, peanut, whole cereals, legumes, meat and fish. About half of the requirement is met by the conversion of tryptophan to niacin. About 60 mg of tryptophan will yield 1 mg of niacin.

### Recommended Daily Allowance (RDA)
Normal requirement is 20 mg/day. During lactation, additional 5 mg are required.

### Therapeutic Use of Niacin
Nicotinic acid inhibits the flux of free fatty acids from adipose tissue; so acetyl CoA pool is reduced; and hence serum cholesterol is lowered.

### Toxicity of Niacin
Nicotinic acid when given orally or parenterally produces a transient vasodilatation of the cutaneous vessels and **histamine release**. The reaction is accompanied by itching, burning and tingling. Intake of nicotinic acid in excess of 50 mg/day may lead to liver damage.

### VITAMIN B$_6$

#### Co-enzyme Form
Vitamin B$_6$ is the term applied to a family of 3 related pyridine derivatives; pyridoxine (alcohol), pyridoxal (aldehyde) and pyridoxamine. Active form of pyridoxine is **pyridoxal phosphate (PLP)** (Fig. 34.9). It is synthesized by pyridoxal kinase, utilizing ATP.

Main supply of B$_6$ compounds in food is in the form of pyridoxine which can be readily converted to pyridoxal and pyridoxamine in the body. Richard Kuhn (Nobel prize 1938) did the isolation and structural analysis.

#### Functions of Pyridoxal Phosphate
The pyridoxal phosphate (PLP) acts as co-enzyme for many reactions in **amino acid metabolism** (Box 34.6).

1. **Transamination**
   These reactions are catalyzed by amino transferases (transaminases) which employ PLP as the co-enzyme (Fig. 14.8). For example:

   \[
   \text{Alanine} + \text{Alpha keto glutarate} \rightarrow \text{Pyruvate} + \text{Glutamic acid (Enzyme Alanine transaminase)}.
   \]

   The clinical significance of blood levels of transaminases is given in Chapter 23.
2. Decarboxylation
All decarboxylation reactions of amino acids require PLP as co-enzyme. A few examples are given below:

i. Glutamate $\rightarrow$ GABA (gamma amino butyric acid) (Fig. 16.2). GABA is an inhibitory neurotransmitter, and hence in B₆ deficiency, especially in children, convulsions may occur.

ii. Histidine $\rightarrow$ histamine, which is the mediator of allergy and anaphylaxis (Fig. 16.9).

iii. 5-hydroxy tryptophan $\rightarrow$ serotonin (Fig. 17.10).

iv. Cysteine $\rightarrow$ taurine (Fig. 15.22).

v. Serine $\rightarrow$ ethanol amine (Fig. 15.12).

3. Sulfur Containing Amino Acids
PLP plays an important role in methionine and cysteine metabolism. For details see Chapter 15.

a. Homocysteine + Serine $\rightarrow$ Cystathionine.
(Enzyme Cystathionine synthase) (Fig.15.15)

b. Cystathionine $\rightarrow$ Homoserine + Cysteine
(Enzyme Cystathionase)

Both these reactions require PLP. Hence in vitamin B₆ deficiency homocysteine in blood is increased. Homocysteine level is correlated with myocardial infarction. Therefore, pyridoxine is used to prevent homocysteinemia.

4. Heme Synthesis
ALA synthase is a PLP dependent enzyme. This is the rate limiting step in heme biosynthesis (Fig. 21.4). So, in B₆ deficiency, anemia may be seen.

5. Production of Niacin
Pyridoxal phosphate is required for the synthesis of niacin from tryptophan (one vitamin is necessary for synthesis of another vitamin) (Figs 17.8 and 17.9).

3-hydroxy kynurenine $\rightarrow$ 3-hydroxy anthranilic acid
(Enzyme Kynureninase).

Kynureninase is a PLP dependent enzyme. Hence in vitamin B₆ deficiency niacin production is less. Moreover kynurenine cannot be converted further, which is metabolized to xanthurenic acid and excreted through urine.

6. Glycogenolysis
Phosphorylase enzyme (glycogen to glucose-1-phosphate) requires PLP. In fact, more than 70% of total PLP content of the body is in muscles, where it is a part of the phosphorylase enzyme.

Deficiency Manifestations of Pyridoxine
1. Neurological Manifestations
In vitamin B₆ deficiency, PLP dependent enzymes function poorly. So, serotonin, epinephrine, noradrenalin and gamma amino butyric acid (GABA) are not produced properly. Neurological symptoms are therefore quite common in B₆ deficiency. In children, B₆ deficiency leads to convulsions due to decreased formation of GABA. PLP is involved in the synthesis of sphingolipids; so B₆ deficiency leads to demyelination of nerves and consequent peripheral neuritis. This is reversible with high doses of B₆.

2. Dermatological Manifestations
Deficiency of B₆ will also affect tryptophan metabolism. Since niacin is produced from tryptophan, B₆ deficiency in turn leads to niacin deficiency which is manifested as pellagra.

3. Hematological Manifestations
In adults hypochromic microcytic anemia may occur due to the inhibition of heme biosynthesis. Impaired antibody formation is also reported.

The metabolic disorders which respond to vitamin B₆ therapy are xanthurenic aciduria and homocystinuria.

Assay of Vitamin B₆
Vitamin B₆ status is assayed by the activation of erythrocyte transaminases by addition of pyridoxal phosphate in the reaction mixture.

Effect of Drugs on Vitamin B₆
i. INH: Isonicotinic acid hydrazide (isoniazid) is an antituberculosis drug. It inhibits pyridoxal kinase; reduces the formation of PLP and causes vitamin B₆ deficiency.

ii. Cycloserine: It acts as B₆ antagonist.

iii. Oral contraceptives: Mild vitamin B₆ deficiency may be seen in women taking oral contraceptive pills.

iv. Ethanol: It is converted to acetaldehyde, which inactivates PLP. Hence B₆ deficiency neuritis is quite common in alcoholics.

Dietary Sources of Vitamin B₆
Rich sources are yeast, rice polishing, wheat germs, cereals, legumes (pulses), oil seeds, egg, milk, meat, fish and green leafy vegetables.
Vitamin B₆ requirements are related to protein intake and not to calorie intake (Box 34.6). It is recommended that adults need 1 to 2 mg/day. During pregnancy and lactation, the requirement is increased to 2.5 mg/day.

Toxicity of Vitamin B₆
Doses over 100 mg may lead to sensory neuropathy. Further excess is manifested by imbalance, numbness, muscle weakness and nerve damage.

PANTOTHENIC ACID

The Greek word “pantos” means everywhere. As the name suggests, it is widely distributed in nature. Pantothenic acid contains beta alanine and D-pantoic acid in amide linkage (Fig. 34.10). Lipmann discovered the CoA in 1946 (Nobel prize in 1953).

Structure
Synthesis of the CoA is shown in Figure 34.11; it needs the expenditure of 4 high energy bonds. Pantothenic acid and beta mercaptoethanol amine are parts of co-enzyme A (CoA) (Fig. 34.12). The CoA is a nucleotide.

Co-enzyme Activity of Pantotethenic Acid

i. The beta mercaptoethanol amine (NH₂-CH₂-CH₂-SH) contains one thiol or sulfhydryl (-SH) group. It is the active site where acyl groups are carried. Therefore the co-enzyme A is sometimes abbreviated as CoA-SH to denote this active site.

ii. The thio ester bond in acyl-CoA is a high energy bond. These acyl groups are transferred to other acceptors, for example:

\[\text{Acetyl CoA} + \text{Choline} \rightarrow \text{Acetyl choline} + \text{CoA}\]  (enzyme is acetyl choline synthase)

iii. Acyl groups are also accepted by the CoA molecule during the metabolism of other substrates, for example:

\[\text{Pyruvate} + \text{CoA} + \text{NAD}^+ \rightarrow \text{AcetylCoA} + \text{CO}_2 + \text{NADH}\]  (Enzyme is pyruvate dehydrogenase).

iv. The important CoA derivatives are:
   a. Acetyl CoA
   b. Succinyl CoA
   c. HMG CoA
   d. Acyl CoA.

These reactions of acetyl CoA and succinyl CoA are summarized in Figure 34.13.

v. Co-enzyme A is an important component of fatty acid synthase complex. The ACP (acyl carrier protein) also contains pantothetic acid.
Deficiency of Pantothenic Acid
Gopalan's Burning Foot Syndrome is manifested as paresthesia (burning, lightning pain) in lower extremities, staggering gait due to impaired co-ordination and sleep disturbances.

These deficiency manifestations are rare in human beings. The syndrome is seen during famine, in prison camps, in chronic alcoholics and in some renal dialysis patients.

In experimental animals, deficiency has resulted in anemia (due to reduced heme synthesis from succinyl CoA), reduced steroidogenesis (due to lack of acetyl CoA), dermatitis, fatty liver and adrenal necrosis.

Sources of Pantothenic Acid
It is widely distributed in plants and animals. Moreover, it is synthesized by the normal bacterial flora in intestines. Therefore, deficiency is very rare. Yeast, liver and eggs are good sources.

Requirement of Pantothenic Acid
RDA is assumed to be about 10 mg/day.

BIOTIN
In old literature Biotin was known as anti-egg white injury factor. Biotin was isolated in 1942 by Vincent du Vigneaud, who was awarded Nobel prize in 1955.
2. **Propionyl CoA carboxylase**
Propionyl CoA + CO$_2$ + ATP $\rightarrow$ Methyl malonyl CoA + ADP + Pi  
(Step 1, Fig. 11.11).

3. **Pyruvate carboxylase**
Pyruvate + CO$_2$ + ATP $\rightarrow$ Oxaloacetate + ADP + Pi  
(Fig. 9.24). This is important in two aspects. One, it provides the oxaloacetate, which is the catalyst for TCA cycle. Second, it is an important enzyme in the gluconeogenic pathway.

**Biotin-Independent Carboxylation Reactions**

i. Carbamoyl phosphate synthetase, which is the stepping stone for urea and pyrimidine synthesis (Step 1, Fig. 14.13).

ii. Addition of CO$_2$ to form C6 in purine ring.

iii. Malic enzyme, converting pyruvate to malate.

**Biotin Antagonists**

i. Avidin, a protein present in egg white has great affinity to biotin. Hence intake of raw (unboiled) egg may cause biotin deficiency. Biotin was originally named as anti-egg-white-injury-factor.

ii. Avidin is heat labile, and boiling of egg will neutralize the inhibitory activity. One molecule of avidin can combine with four molecules of biotin. It is curious that egg white contains avidin and egg yolk contains biotin.

iii. The affinity of avidin to biotin is greater than most of the usual antigen-antibody reactions. Therefore avidin-biotin system is commonly utilized for detection of pathogens in the ELISA test.

**FOLIC ACID**

The name is derived from the Latin word *folium*, which means leaf of vegetable. **Folic acid is abundant in vegetables.** Angier in 1941 established the chemical structure of folic acid. The name folic acid was assigned by Mitchell, Snell and Williams.

**Chemistry of Folic Acid**

The Latin word *folium* means leaf of vegetable. Folic acid is abundant in vegetables. It is composed of three constituents. The pteridine group linked with para amino benzoic acid (PABA)) is called pteroic acid. It is then attached to glutamic acid to form pteroyl glutamic acid or folic acid (see Fig. 34.16). In nature, polyglutamates are seen where up to seven glutamate residues are linked to the pteroyl group. Folacin is the generic name for such folic acid related compounds. **Folic acid is soluble in water. When exposed to light, it is rapidly destroyed.**

**Absorption of Folic Acid**

Folic acid is readily absorbed by the upper part of jejunum. In the blood, it is transported by beta globulins. It is taken up by the liver where the co-enzymes are produced. Folic acid is not stored in tissues.

There are different tissue specific transporters for folic acid. These high affinity binding proteins are anchored on plasma...
membrane. Folate-transporter complex is internalized by a non-clathrin mediated endocytosis. The term "potocytosis" is used to denote the recycling of transport proteins by vesicular structures, named caveolae.

Co-enzyme Functions of Folic Acid

A. The folic acid is first reduced to 7,8-dihydrofolic acid and further reduced to 5,6,7,8-tetrahydrofolic acid (THFA) (Fig. 34.17). Both reactions are catalyzed by NADPH dependent folate reductase.

B. The THFA is the carrier of one-carbon groups. One carbon compound is an organic molecule that contains only a single carbon atom. The following groups are one carbon compounds:
   i. Formyl (-CHO)
   ii. Formimino (-CH=NH)
   iii. Methenyl (-CH=)
   iv. Methylene (-CH2–)
   v. Hydroxymethyl (-CH2OH)
   vi. Methyl (-CH3).

C. These one carbon compounds are attached either to the 5th or to the 10th or to both 5 and 10 nitrogen atoms of THFA (Fig. 34.18). The one carbon metabolism and their inter-conversions are given in detail in Figure 14.18.

D. Methyl group in N5-methyl THFA is used for synthesis of active methionine, which takes part in transmethylation reactions (Fig. 34.19). Such transmethylation reactions are required for synthesis of choline, epinephrine, creatine, etc. (Table 15.1).

Causes for Folate Deficiency

Folic acid deficiency is very common in India, and is perhaps the most commonly seen vitamin deficiency.

i. Pregnancy: Folate deficiency is commonly seen in pregnancy, where requirement is increased.

ii. Defective absorption: In sprue, celiac disease, gluten induced enteropathy, resection of jejunum and short-circuiting of jejunum in gastroileostomy, absorption is defective.

iii. Drugs: In the diet, folacins are mainly in polyglutamate form. Gastrointestinal enzymes in the gut remove the glutamate residues and only the mono-glutamate form of folic acid is absorbed. Anticonvulsant drugs (hydantoin,
dilantin, phenytoin, phenobarbitone) will inhibit the intestinal enzyme, so that folate absorption is reduced.

iv. **Hemolytic anemias:** As requirement of folic acid becomes more, deficiency is manifested.

v. **Dietary deficiency:** Absence of vegetables in food for prolonged periods may lead to deficiency.

vi. **Folate trap:** The only way for regeneration of free THF is step No.1 in Figure 34.19. When B12 is deficient, this reaction cannot take place, leading to folate deficiency (see under vitamin B12).

### Deficiency Manifestations

1. **Reduced DNA synthesis**
   In folate deficiency, THFA is reduced and thymidylate synthase enzyme is inhibited. Hence dUMP is not converted to dTMP. So dTTP is not available for DNA synthesis. Thus cell division is arrested. Very rapidly dividing cells in bone marrow and intestinal mucosa are therefore most seriously affected.

2. **Macrocytic Anemia**
   i. It is the most characteristic feature of folate deficiency (Fig. 34.20). During erythropoiesis, DNA synthesis is delayed, but protein synthesis is continued. Thus hemoglobin accumulates in RBC precursors. This asynchrony or dissociation between the maturity of nucleus and cytoplasm is manifested as immature looking nucleus and mature eosinophilic cytoplasm in the bone marrow cells.
   
   ii. **Reticulocytosis** is often seen. These abnormal RBCs are rapidly destroyed in spleen. This hemolysis leads to the reduction of lifespan of RBC. Reduced generation and increased destruction of RBCs result in anemia.
   
   iii. **Leukopenia** and thrombocytopenia are also manifested.

iv. The peripheral blood picture in folate deficiency is described as **macrocytic**, and in cobalamin deficiency as **megaloblastic**. In B12 deficiency, there are additional neurological symptoms.

3. **Homocysteinemia**
   Folic acid deficiency may cause increased homocysteine levels in blood. Plasma homocysteine levels above 15 micromoles / L is known to increase the risk of coronary artery diseases. Providing adequate doses of pyridoxine, B12 and folic acid may lower the homocysteine levels.

4. **Birth Defects**
   Folic acid deficiency during pregnancy may lead to homocysteinemia and neural tube defects in the fetus. Folic acid prevents birth defects (fetal malformations such as spina bifida). So, supplementation of folic acid from early pregnancy is a must to prevent neural tube defects in the child.

5. **Cancer**
   Folic acid is beneficial in prevention of cancer. Folate deficiency contributes to the etiology of bronchial carcinoma and cervical carcinoma.

### Assessment of Folate Deficiency

i. **Blood Level:** Normal folic acid level in serum is about 20 nanogram/ml and about 200 microgram/ml of packed cells. The level is measured by radio-immuno-assay.

ii. **Histidine load test or FIGLU excretion test:** Histidine is normally metabolised to formimino glutamic acid (FIGLU) from which formimino group is removed by THFA. Therefore in folate deficiency, FIGLU is excreted in urine.

iii. **AICAR excretion:** In the purine nucleotide synthesis, the last step is the addition of C2 with the help of N10-formyl THFA (step No. 9 in purine synthesis, Chapter 39). When this is blocked, the precursor, amino imidazole carboxamide ribosyl-5-phosphate (AICAR) accumulates and is excreted in urine.

iv. **Peripheral blood picture.**

### Sources of Folic Acid
Rich sources of folate are yeast, green leafy vegetables. Moderate sources are cereals, pulses, oil seeds and egg. Milk is a poor source for folic acid.

### Recommended Daily Allowance (RDA)
The requirement of free folate is 200 microgram/day. In pregnancy the requirement is increased to 400 microgram/day and during lactation to 300 microgram/day.
Folic Acid Therapy
Therapeutic dose is 1 mg of folic acid per day orally. Folic acid alone should not be given in macrocytic anemia because it may aggravate the neurological manifestation of B₁₂ deficiency. So, folic acid and vitamin B₁₂ are given in combination to patients. Regular supplementation of folic acid may reduce the incidence of birth defects, cardiovascular diseases and cancers.

Toxicity of Folic Acid
Doses over 1 mg may cause aggravation of vitamin B₁₂ deficiency and may precipitate nerve damage. Since solubility of folic acid is low, large doses should not be given parenterally, as there is danger of crystallization in kidney tubules leading to renal damage.

Folate Antagonists
1a. Sulphonamides
They have structural similarity with PABA (Fig. 34.21). Therefore they competitively inhibit the enzyme responsible for the incorporation of PABA into dihydropteroic acid, the immediate precursor of folic acid (see Competitive Inhibition, Chapter 5). Bacteria can synthesise folic acid from the components, pteridine, PABA and glutamate. When sulphonamides are given, such micro-organisms cannot synthesise folic acid and hence their growth is inhibited. As man cannot synthesise folic acid, the entire molecule has to be supplied in the diet. Thus sulphonamides are very good antibacterial agents, which do not affect the human cells. Gerhard Domagk discovered the antibacterial effect of Prontosil (a sulphonamide) in 1932 for which he was awarded Nobel prize in 1939.

1b. Pyrimethamine
This antifolate agent is used against plasmodial infections (antimalarial drug) (Fig. 34.21). Gertrude Elion synthesised pyrimethamine, who got Nobel prize in 1988.

1c. Aminopterin and Amethopterin
Aminopterin (4-amino folic acid) and amethopterin (methotrexate) (4-amino, 10-methyl folic acid) are powerful inhibitors of folate reductase and THFA generation. Thus these drugs decrease the DNA formation and cell division. They are widely used as anticancer drugs, especially for leukemias and choriocarcinomas. Folinic acid (citrovorum factor) is given to rescue the patient from toxicity of methotrexate.

VITAMIN B₁₂
Synonyms are cobalamin, extrinsic factor (EF) of Castle and antipernicious anemia factor. In 1849, Thomas Addison described the pernicious anemia. William Murphy and George Minot showed that liver therapy is very effective to treat pernicious anemia. For this work, they were awarded Nobel prize in 1934. Dorothy Hodgkin suggested the structure by X-ray diffraction studies (Nobel prize, 1964). Later Robert Woodward synthesized B₁₂ and proved the structure (Nobel prize, 1965).

Chemistry
Vitamin B₁₂ is water soluble, heat stable and red in color. It contains 4.35% cobalt by weight. It contains one cobalt atom. Four pyrrole rings co-ordinated with a cobalt atom is called a Corrin ring. Note the similarity between the Corrin ring and the porphyrin ring system (Chapter 21). The 5th valency of the cobalt is covalently linked to a substituted benzimidazole ring. This is then called cobalamin. The 6th valency of the cobalt is satisfied by any of the following groups: cyanide, hydroxyl, adenosyl or methyl (Fig. 34.22A).

a. Cyanocobalamin
When cyanide is added at the R position, the molecule is called cyanocobalamin. During the isolation procedure, cyanide is added to get stable crystals. The CN group has no physiological function, it is only a laboratory artefact. Oral preparations are in this form.
b. Hydroxy cobalamin
When hydroxyl group is attached at the R position, it is called hydroxy cobalamin or vitamin $B_{12a}$. Injectable preparations are in this form.

c. Adenosyl cobalamin ($Ado-B_{12}$)
When taken up by the cells, these groups are removed and deoxy adenosyl cobalamin or $Ado-B_{12}$ is formed (Fig. 34.22B). This is the major storage form, seen in liver.

d. Methyl cobalamin
When the methyl group replaces adenosyl group, it is known as methyl cobalamin. This is the major form seen in blood circulation as well as in cytoplasm of cells. The $Ado-B_{12}$ and methyl $B_{12}$ are the functional co-enzymes in the body.

2. Absorption of Vitamin $B_{12}$

i. Absorption of vitamin $B_{12}$ requires two binding proteins. First is the intrinsic factor (IF) of Castle (Fig. 34.23). William B Castle described it in 1929. The $B_{12}$ is otherwise known as extrinsic factor (EF), that is, the factor derived from external sources. Intrinsic factor is secreted by the gastric parietal cells. It is a glycoprotein with a molecular weight of 50,000.

ii. The second factor is cobalophilin, secreted in the saliva. Gastric pepsin release the vitamin from proteins of the food, and then $B_{12}$ binds with cobalophilin. In duodenum, cobalophilin is hydrolyzed by trypsin of pancreatic juice; vitamin is released, and then vitamin binds to intrinsic factor. In pancreatic insufficiency (absence of trypsin), the vitamin may not be released. Then vitamin-cobalophilin complex is excreted, resulting in vitamin deficiency.

Transport and Storage
In the blood, methyl $B_{12}$ form is predominant. Transcobalamin, a glycoprotein, is the specific carrier (Fig. 34.23). It is stored in the liver cells, as $Ado-B_{12}$ form, in combination with transcorrin.
The metabolism of odd chain fatty acids, valine, isoleucine, methionine and threonine leads to the production of methyl malonyl CoA.

B. Homocysteine Methyl Transferase
Step 2 in Figure 34.19 is catalyzed by the enzyme methionine synthase or homocysteine methyl transferase. The steps marked as 1 and 2 in Figure 34.19 need the activity of vitamin B₁₂ (methyl cobalamin).

C. Methyl Folate Trap and Folate Deficiency
The production of methyl THFA is an irreversible step (Fig. 14.16). Therefore, the only way for generation of free THFA is step No. 1 in Figure 34.19. When B₁₂ is deficient, this reaction cannot take place. This is called the methyl folate trap. This leads to the associated folic acid scarcity in B₁₂ deficiency.

Causes of B₁₂ Deficiency
1. Nutritional
Nutritional vitamin B₁₂ deficiency is very common in India, especially among vegetarians of low socio-economic group. The only source for B₁₂ in vegetarian diet is curd / milk, and lower income group may not be able to afford it.

2. Decrease in absorption
Absorptive surface is reduced by gastrectomy, resection of ileum and malabsorption syndromes.

3. Addisonian pernicious anemia
It is very rare in India, but common in European countries. When it was described in 1849 by Thomas Addison, it was pernicious (fatal), without any known remedy. It is manifested usually in persons over 40 years. It is an autoimmune disease with a strong familial background. Antibodies are generated against IF. So, IF becomes deficient, leading to defective absorption of B₁₂ (Fig. 34.24).

4. Gastric atrophy
Although true Addisonian pernicious anemia is rare, similar atrophy of gastric epithelium leading to deficiency of IF and decreased B₁₂ absorption is common in India. In chronic iron deficiency anemia, there is generalized mucosal atrophy. In about 40% cases of iron deficiency anemia, super-added gastric atrophy is seen.

Generally, B complex vitamins are not stored in the body, B₁₂ is an exception. Whole liver contains about 2 mg of B₁₂, which is sufficient for the requirement for 2-3 years. So, B₁₂ deficiency is seen only years after gastrectomy.

Functional Role of B₁₂
A. Methyl Malonyl CoA Isomerase
D-Methyl malonyl CoA is formed in the body from propionyl CoA. It is then converted to L form by a racemase and then isomerized by methyl malonyl CoA mutase (containing Ado–B₁₂) to succinyl CoA, which enters into citric acid cycle (see Fig. 11.11). In B₁₂ deficiency, methyl malonyl CoA is excreted in urine (methyl malonic aciduria).
5. Pregnancy
Increased requirement of vitamin in pregnancy is another common cause for vitamin B₁₂ deficiency in India.

6. Fish tapeworm
Although not seen in India, the fish tapeworm, *Diphilobothrium latum* infection is common in Scandinavian countries where eating live fish is a delicacy. This tapeworm has a special affinity to B₁₂ causing reduction in available vitamin.

Deficiency Manifestations
i. Folate trap: Vitamin B₁₂ deficiency causes simultaneous folate deficiency due to the folate trap. Therefore all the manifestations of folate deficiency are also seen (for details see under folic acid).

ii. Megaloblastic anemia: In the peripheral blood, megaloblasts and immature RBCs are observed (Fig. 34.20).

iii. Abnormal homocysteine level: In vitamin B₁₂ deficiency, step No. 2 (Fig. 34.19) is blocked, so that homocysteine is accumulated, leading to homocystinuria. Homocysteine level in blood has a positive correlation with myocardial infarction. So, B₁₂ and folic acid are protective against ischemic heart disease.

iv. Demyelination: In vitamin B₁₂ deficiency, step 3 (Fig. 34.19) is also suppressed due to the non-availability of active methionine. Therefore methylation of phosphatidyl ethanolamine to phosphatidyl choline is not adequate. This leads to deficient formation of myelin sheaths of nerves, demyelination and neurological lesions.

v. Subacute combined degeneration: Damage to nervous system is seen in B₁₂ deficiency (but not in folate deficiency). There is demyelination affecting cerebral cortex as well as dorsal column and pyramidal tract of spinal cord. Since sensory and motor tracts are affected, it is named as combined degeneration. Symmetrical paresthesia of extremities, alterations of tendon and deep senses and reflexes, loss of position sense, unsteadiness in gait, positive Romberg’s sign (falling when eyes are closed) and positive Babinski’s sign (extensor plantar reflex) are seen.

vi. Achlorhydria: Absence of acid in gastric juice is associated with vitamin B₁₂ deficiency.

Assessment of B₁₂ Deficiency
i. Serum B₁₂: It is quantitated by radio-immuno-assay or by ELISA.

ii. Schilling test: Radioactive labelled (Cobalt-60) vitamin B₁₂, one microgram is given orally. Simultaneously an intramuscular injection of unlabeled vitamin B₁₂ is given, in order to saturate tissues with normal vitamin B₁₂. So, radioactive vitamin B₁₂ will not bind to body tissues. Therefore, the entire absorbed radioactivity will pass into the urine. The patient’s urine is then collected over the next 24 hours to assess the absorption. In a normal person, the ingested vitamin B₁₂ will be absorbed into the body. Since the liver receptors for vitamin B₁₂ are saturated by the injection, much of the ingested vitamin B₁₂ will be excreted in the urine. In patients with pernicious anemia or with deficiency due to impaired absorption, less than 5% of the radioactivity is detected in urine. If an abnormality is found, the test is repeated, with radioactive vitamin plus intrinsic factor given orally, and urine is collected for 24 hours. In pernicious anemia, there is lack of intrinsic factor, so that the first test is abnormal; but the second test is normal.

iii. Methyl malonic acid: It is seen in urine.

iv. FIGLU excretion test: (see folic acid).

v. Peripheral smear: Peripheral blood and bone marrow morphology shows megaloblastic anemia (Fig. 34.20).

vi. Homocystinuria: (see Chapter 15, under Methionine).

Treatment
If megaloblastic anemia is treated with folic acid alone, the anemia may improve, but associated neurological symptoms are aggravated. Hence all macrocytic anemias are generally treated with folate and vitamin B₁₂. Therapeutic dose of B₁₂ is 500 to 1000 microgram by intramuscular injections.

Requirement of Vitamin B₁₂
Normal daily requirement is 1-2 microgram/day. During pregnancy and lactation, this is increased to 2 mg/day. Those who take folic acid, should also take vitamin B₁₂. Elderly people are advised to take B₁₂ supplementation.

Dietary Sources
Vitamin B₁₂ is not present in vegetables. Liver is the richest source. Curd is a good source, because lactobacillus can synthesize B₁₂.

CHOLINE

Best and Huntsman (1934) discovered that choline deficiency in the rat produces fatty liver. It plays an active role in transmethylation (see under serine, Chapter 15). Choline is synthesized in the body (Fig. 15.12) and therefore it is not a vitamin. But in view of its importance in nutrition, conventionally, it is included as a member of vitamin B complex. Rice polishings, vegetables, milk, egg and liver are good sources. It is synthesized from serine (Chapter 15).
Chemistry
It is hydroxy ethyl trimethyl amine, or trimethyl ethanol amine (Fig. 34.25A). It is water soluble.

Biochemical Functions
i. Phospholipid synthesis: Choline is a part of phospholipids which are essential constituents of the membranes of all cells.

ii. Myelin sheath: It is made by phospholipids. Demyelination causes severe diseases of nervous system.

iii. Fatty liver: Phospholipids are involved in the transport of fat and cholesterol from the liver. In choline deficiency, neutral fat and cholesterol esters accumulate in liver, leading to fatty liver. Choline is able to prevent fatty liver and cirrhosis (Chapter 11).

iv. Transmethylation reactions: Choline can donate three methyl groups to the one-carbon pool (see one carbon metabolism in Chapter 14). Finally, these methyl groups are transferred to homocysteine to produce methionine, which is used for transmethylation reactions (Chapter 15).

v. Acetyl choline (ACh) synthesis:

Choline acetylase
Choline + Acetyl CoA → Acetyl choline + CoA

Acetyl choline esterase
Acetyl choline → Choline + Acetate

Acetyl Choline
It is synthesized in the neurons, which reaches the presynaptic region of synaptosomes, where ACh is stored in packets. When a nerve impulse reaches, the ACh is liberated into the synaptosome. At the post-synaptic region, the ACh is picked up by the specific receptors, which produces a nerve impulse. Thus the nerve impulse is transmitted through the synapses by the chemical messenger, the ACh. As soon as the nerve impulse is generated in the post-synaptic fiber, the ACh is hydrolyzed by the ACh-esterase.

In 1914, Henry Dale isolated Ach. In 1920, Otto Loewi studied the effect of ACh on nerve transmission. Both of them were awarded Nobel prize in 1936. Later work of Bernard Katz on the effect of Ach on neuromuscular end plates earned him the Nobel prize in 1970.

Clinical Applications
i. The post-synaptic receptors for ACh may be competitively blocked by succinyl choline, a structural analogue of ACh. Then ACh cannot act, producing muscle relaxation. It is widely used as a muscle relaxant during surgery.

ii. Cholinesterase inhibitors (e.g. neostigmine) will allow prolonged action of ACh and therefore nerve impulse is sustained. These drugs are used in myasthenia gravis. Myasthenia is an auto-immune condition, where antibodies are produced against neuromuscular end plate proteins destroying the end plates.

iii. Pseudocholinesterase is seen in RBCs, more in immature cells (see Chapter 23).

INOSITOL
Inositol is hexahydroxy cyclohexane. Out of the many isomers, myo-inositol is seen in tissues (Fig. 34.25B). It is seen in yeast, cereals and milk. Inositol deficiency is unknown to man. Therefore it cannot be considered as a vitamin.

Biochemical Functions of Inositol
1. Studies in tissue culture have revealed that inositol is required for growth of fibroblasts.
2. Inositol is a constituent of certain phospholipids.
3. It occurs in large quantities in mammalian heart muscle.
4. Hexa phosphate of inositol is called phytin. It is found in vegetables, which prevent the absorption of calcium and iron from intestine.

v. Phosphatidyl inositol is an important constituent of cell membranes. In response to extracellular signals, inositol triphosphate (IP3) is released from phosphatidyl inositol. IP3 is a second messenger (Chapter 44). It may allow calcium inflow into the cells, leading to cellular metabolic activation.

6. Peripheral neuropathy, very commonly seen in diabetes mellitus, is associated with inositol metabolism. Decreased inositol in nerve fibers may be the cause for neuropathy.

7. It is a lipotropic factor and prevents fatty liver.

ASCORBIC ACID (VITAMIN C)
A description of scurvy was found in the Ebers papyrus written in 1500 B.C. in Egypt. During the voyage of Vasco da Gama, around the cape of Good Hope to India in 1498, he lost two-third of the crew due to scurvy. The French explorer, Jacques Cartier, in 1536, during the voyages to discover eastern parts of Canada, was laid up with scurvy. A friendly native gave an extract from the leaves of spruce tree, which produced remarkable cure to scurvy (Fig. 34.26). James Lind published ‘Treatise on Scurvy’, in 1753. These observations led to compulsory rationing of lime or lemon juice to all the crew of the British Royal Navy from 1795 onwards. So the British sailors were nicknamed as “Limeys”. However, it helped to eliminate scurvy from the British Navy, while opponents continued to suffer. No wonder, in course of time, Britain had the colonies in which the sun never set. In 1907, Holst and Trochlich produced scurvy in guinea pigs. Zilva and associates, in 1928, showed that the antiscorbutic factor present in lemon juice is a reducing...
substance. The factor was isolated in 1930 and named as “Hexuronic acid” by Albert Szent-Gyorgi (Nobel prize, 1937). In 1933, Haworth established the molecular structure. He renamed it as ascorbic acid (Nobel prize, 1937).

Chemistry of Vitamin C
It is water soluble and is easily destroyed by heat, alkali and storage. In the process of cooking, 70% of vitamin C is lost.

The structural formula of ascorbic acid closely resembles that of carbohydrates (Fig. 34.28). The strong reducing property of vitamin C depends on the double-bonded (enediol) carbons.

Only L-ascorbic acid and dehydroascorbic acid have antiscorbutic activity. The D-ascorbic acid has no activity.

Biosynthesis of Ascorbic Acid in Animals
Most animals and plants can synthesize ascorbic acid from glucose. The pathway is described in Figure 10.7. Man, higher primates, guineapigs and bats are the only species which cannot synthesize ascorbic acid (block in gulono lactone oxidase step). They lack the genes responsible for the synthesis of this enzyme. The vitamin therefore should be supplied in the diet of these species. The staple diet of primates contains fruits and vegetables rich in ascorbic acid, and so the gene deletion will have no deleterious effect in primates. Human beings, of course, carried over this gene deletion.

Metabolism of Ascorbic Acid
i. Ascorbic acid is readily absorbed from gastrointestinal tract. The vitamin is excreted in urine. Since vitamin C is a strong reducing agent, the Benedict’s test will be positive in the urine sample after the vitamin administration.

ii. Oxidation of ascorbic acid yields dehydro ascorbic acid, which is oxidized further to oxalic acid through diketo-L-gulonic acid (Fig. 34.28). Ascorbic acid is partly excreted unchanged and partly as oxalic acid. Most of the oxalates in urine are derived from ascorbic acid, and the rest from glycine metabolism.

iii. The ascorbic acid level varies between 0.7 to 1.2 mg/100 ml of plasma and 25 mg/100 cc of WBC. A low level in blood is noted in women taking contraceptive pills and also in chronic alcoholics.

![Fig. 34.26](image-url) Red Indian gives the leaves to Cartier
![Fig. 34.27](image-url) (A) Gingivitis and bleeding gum in vitamin C deficiency. (B) Lime and (C) gooseberry are good sources of vitamin C

![Fig. 34.28](image-url). Vitamin C: Structure and catabolism
iv. A very high concentration of vitamin C is observed locally in healing wounds. Vitamin C is essential for wound healing.

Biochemical Functions of Vitamin C

1. Reversible oxidation-reduction
It can change between ascorbic acid and dehydro-ascorbic acid. Most of the physiological properties of the vitamin could be explained by this redox system.

2. Hydroxylation of proline and lysine
Ascorbic acid is necessary for the post-translational hydroxylation of proline and lysine residues (Fig. 34.29). Hydroxyproline and hydroxylysine are essential for the formation of cross links in the collagen, which gives the tensile strength to the fibres. This process is absolutely necessary for the normal production of supporting tissues such as osteoid, collagen and intercellular cement substance of capillaries.

3. Tryptophan metabolism
Ascorbic acid is necessary for the hydroxylation of tryptophan to 5-hydroxy tryptophan. This is required for the formation of serotonin (see Fig. 17.10).

4. Tyrosine metabolism
Vitamin C helps in the oxidation of parahydroxy phenyl pyruvate to homogentisic acid (see Fig. 17.2).

5. Iron metabolism
Ascorbic acid enhances the iron absorption from the intestine (Chapter 35). Ascorbic acid reduces ferric iron to ferrous state, which is preferentially absorbed.

6. Hemoglobin metabolism
It is useful for re-conversion of met-hemoglobin to hemoglobin.

7. Folic acid metabolism
Ascorbic acid is helping the enzyme folate reductase to reduce folic acid to tetrahydrofolic acid (Fig. 34.17). Thus it helps in the maturation of RBC.

8. Steroid synthesis
Large quantities of vitamin C are present in adrenal cortex. The ascorbic acid is depleted by ACTH stimulation. So the vitamin has some role in adrenal steroidogenesis. Vitamin C helps in the synthesis of bile acids from cholesterol. The initial 7-alpha-hydroxylation step is stimulated by the vitamin.

9. Phagocytosis
Ascorbic acid stimulates phagocytic action of leukocytes and helps in the formation of antibodies.

10. Anti-oxidant property
As an anti-oxidant (Chapter 20), it may prevent cancer formation. Aniline dyes are known to induce bladder cancer in factory workers. Daily intake of vitamin C reduces this risk for cancer.

11. Cataract
Vitamin C is concentrated in the lens of eye. Regular intake of ascorbic acid reduces the risk of cataract formation.

Deficiency Manifestations of Vitamin C

1. Scurvy
Gross deficiency of vitamin C results in scurvy.

2. Infantile scurvy (Barlow’s disease)
In infants between 6 to 12 months of age, (period in which weaning from breast milk), the diet should be supplemented with vitamin C sources. Otherwise, deficiency of vitamin C is seen.

3. Hemorrhagic tendency
In ascorbic acid deficiency, collagen is abnormal and the intercellular cement substance is brittle (Fig. 34.29). So capillaries are fragile, leading to the tendency to bleed even under minor pressure.
Subcutaneous hemorrhage may be manifested as **petechiae** in mild deficiency and as **ecchymoses** or even **hematoma** in severe conditions. If a sphygmomanometer cuff is placed in the forearm, and the pressure is kept for 5 minutes, petechiae may be seen under the skin. This is a useful clinical test.

4. Internal hemorrhage
In severe cases, hemorrhage may occur in the conjunctiva and retina. Internal bleeding may be seen as epistaxis, hematuria or melena.

5. Oral cavity
In severe cases of scurvy, the **gum** becomes painful, **swollen** and **spongy** (Fig. 34.27A). The pulp is separated from the dentine and finally teeth are lost. Wound healing may be delayed.

6. Bones
In the bones, the deficiency results in the failure of the osteoblasts to form the intercellular substance, **osteoid**. Without the normal ground substance, the deposition of bone is arrested. The resulting **scorbutic bone** is **weak** and fractures easily. There may be hemorrhage into joint cavities. Painful swelling of joints may prevent locomotion of the patient.

Vitamin C and vitamin B are essential nutrients to maintain bone density and bone quality. Recent literature clearly shows that vitamin C and B affect bone quality determinant "collagen cross-link formation". Mildly elevated plasma homocysteine levels induced by vitamin B insufficiency and methylenetetrahydrofolate reductase (MTHFR) deteriorate normal collagen cross-link formation.

7. Anemia
In **vitamin C** deficiency, **microcytic, hypochromic anemia** is seen. Poikilocytosis and anisocytosis are also common in anemia due to deficiency of vitamin C. The reasons for anemia may be:

- Loss of blood by hemorrhage
- Decreased iron absorption
- Decreased tetrahydrofolic acid
- Accumulation of met-hemoglobin.

**Dietary Sources of Vitamin C**
Rich sources are **amla** (Indian gooseberry) (700 mg/100 g), **guava** (300 mg/100 g), lime, lemon and green leafy vegetables (Figs 34.27B and C).

**Requirement of Vitamin C**
Recommended daily allowance is 75 mg/day (equal to 50 ml orange juice). During pregnancy, lactation, and in aged people requirement may be 100 mg/day.

**Therapeutic Use of Vitamin C**

i. Vitamin C is used as an adjuvant in infections. Beneficial effect of ascorbic acid is reported in the treatment of tuberculosis, when plasma level is kept near to saturation point. Clinical dose is 500 mg per day.

ii. Because of its power to **heal wounds**, vitamin C has been recommended for treatment of ulcer, trauma and burns. Except in scurvy and sub-scorbutic conditions the therapeutic use of vitamin is not specific.

**Megadose of Vitamin C**
Linus Pauling (Nobel laureate) advocated megadoses (2000-5000 mg) of vitamin to prevent infections. But there is no clear evidence to support this theory. Classical picture of scurvy did not include common cold or respiratory infections as major features. There is experimental evidence in animals that ageing process is prevented by megadoses of vitamin C.

**Toxicity of Vitamin C**
Since it is a water soluble substance, excess vitamin C is excreted, and not accumulated in the body. However, more than 2000 mg of vitamin C daily for a long time can cause iron overload, because vitamin C helps in absorption of iron.
CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:

1. Calcium, availability and functions
2. Factors regulating blood calcium level
3. Calcium, clinical applications
4. Phosphorus
5. Magnesium
6. Sulfur
7. Iron absorption, transport, deficiency
8. Copper
9. Zinc
10. Fluoride
11. Selenium
12. Manganese, Molybdenum, Cobalt, Nickel
13. Chromium, Lithium

Minerals are essential for the normal growth and maintenance of the body. If the daily requirement is more than 100 mg, they are called major elements or macrominerals. They are listed in Box 35.1. Deficiencies of micronutrients afflict more than 50% of the world’s population, result in increased morbidity and mortality rates, loss of productivity, and sometimes permanent impairment of cognitive development in infants and children.

If the requirement of certain minerals is less than 100 mg/day, they are known as minor elements or microminerals or trace elements. They are shown in Box 35.1, in order of their essentially:

The following minerals are necessary for the body; but their exact functions are not known. They are chromium, nickel, bromine, lithium and barium. The following minerals are seen in tissues, but are nonessential and are contaminants in foodstuffs. These are rubidium, silver, gold, and bismuth. The following minerals are toxic and should be avoided: aluminium, lead, cadmium and mercury.

CALCIUM (Ca++)

Total calcium in the human body is about 1 to 1.5 kg, 99% of which is seen in bone and 1% in extracellular fluid.

Sources of Calcium

Milk is a good source for calcium. Calcium content of cow’s milk is about 100 mg/100 ml. Egg, fish and vegetables are medium sources for calcium. Cereals (wheat, rice) contain only small amount of calcium. But cereals are the staple diet in India. Therefore, cereals form the major source of calcium in Indian diet.

Daily Requirement of Calcium

An adult needs 500 mg per day and a child about 1200 mg/day. Requirement may be increased to 1500 mg/day during pregnancy and lactation. After the age of 50, there is a general tendency for osteoporosis, which may be prevented by increased calcium (1500 mg/day) plus vitamin D (20 microgram/day).
Absorption

A. Mechanism of absorption of calcium

Absorption is taking place from the first and second part of duodenum. Calcium is absorbed against a concentration gradient and requires energy. Absorption requires a carrier protein, helped by calcium-dependent ATPase.

Out of the 500 mg of calcium taken orally per day, 400 mg is excreted in stool and 100 mg is excreted through urine.

B. Factors causing increased absorption

i. Vitamin D: Calcitriol induces the synthesis of the carrier protein (Calbindin) in the intestinal epithelial cells, and so facilitates the absorption of calcium (Fig. 35.1).

ii. Parathyroid hormone: It increases calcium transport from the intestinal cells.

iii. Acidity: It favors calcium absorption.

iv. Amino acids: Lysine and arginine increase calcium absorption.

C. Factors causing decreased absorption

i. Phytic acid: Hexaphosphate of inositol is present in cereals. Fermentation and cooking reduce phytate content.

ii. Oxalates: They are present in some leafy vegetables, which cause formation of insoluble calcium oxalates.

iii. Malabsorption syndromes: Fatty acid is not absorbed, causing formation of insoluble calcium salt of fatty acid.

iv. Phosphate: High phosphate content will cause precipitation as calcium phosphate. The optimum ratio of calcium to phosphorus which allows maximum absorption is 1:2 to 2:1 as present in milk.

Calcium in cells

Calcium is present both in the extracellular and intracellular compartments. However, it is mainly extracellular.

The cell membrane is generally impermeable to calcium ions. Calcium influx into the cell is by Na+/Ca++ exchange mechanism. This mechanism is rapid, but has low affinity for calcium (Fig. 35.2).

Entry of Ca++ into mitochondria is by a calcium uniport system. But calcium ions exit by a Na+-Ca++ antiport system, which in turn is dependent on the Na+-H+-ATPase pump. For calcium channels, see Chapter 2.

Functions of Calcium

1. Activation of enzymes

Calmodulin is a calcium binding regulatory protein, with a molecular weight of 17,000 Daltons. Calmodulin can bind with 4 calcium ions. Calcium binding leads to activation of enzymes. Calmodulin is part of various regulatory kinases. The mechanism of action is summarized in Figure 35.3. Calmodulin-dependent enzymes are listed in Box 35.2.

Box 35.2. Selected List of Enzymes Activated by Ca++ and Mediated by Calmodulin

- Adenyl cyclase
- Ca++ dependent protein kinases
- Ca++-Mg++-ATPase
- Glycerol-3-phosphate dehydrogenase
- Glycogen synthase
- Myosin kinase
- Phospholipase C
- Phosphorylase kinase
- Pyruvate carboxylase
- Pyruvate dehydrogenase
- Pyruvate kinase
Some other enzymes are activated directly by Ca\(^{++}\) without the intervention of calmodulin; examples are pancreatic lipase; enzymes of coagulation pathway; and rennin (milk clotting enzyme in stomach).

### 2. Muscles

Calcium mediates **excitation and contraction** of muscle fibers. Different types of calcium channels are shown in Figure 35.2. Upon getting the neural signal, calcium is released from sarcoplasmic reticulum. Calcium activates ATPase; increases action of actin and myosin and facilitates excitation-contraction coupling. The trigger of muscle contraction is the interaction of calcium with Troponin C (see Chapter 52). The active transport system utilizing calcium binding protein is called **calsequestrin**. Calcium decreases neuromuscular irritability. Calcium deficiency causes tetany.

### 3. Nerve conduction

Calcium is necessary for transmission of nerve impulses from presynaptic to postsynaptic region.

### 4. Secretion of hormones

Calcium mediates secretion of insulin, parathyroid hormone, calcitonin, vasopressin, etc. from the cells.

### 5. Second messenger

Calcium and cyclic AMP are second messengers of different hormones (see Table 44.1). One example is glucagon. Calcium is used as second messenger in systems involving G proteins and inositol triphosphate.

### 6. Vascular permeability

Calcium decreases the passage of serum through capillaries. Thus, calcium is clinically used to reduce allergic exudates.

### 7. Coagulation

Calcium is known as factor IV in blood coagulation cascade. Prothrombin contains gamma-carboxy glutamate residues which are chelated by Ca\(^{++}\) during the thrombin formation (see Chapter 33, under vitamin K).

### 8. Myocardium

Ca\(^{++}\) **prolongs systole**. In hypercalcemia, cardiac arrest is seen in systole. This fact should be kept in mind when calcium is administered intravenously. It should be given very slowly.

### 9. Bone and teeth

The bulk quantity of calcium is used for bone and teeth formation. Bones also act as reservoir for calcium in the body. Osteoblasts induce bone deposition and osteoclasts produce demineralization.

### 10. Calpains

Calpains are a family of calcium-dependent, cysteine proteases (proteolytic enzymes) seen ubiquitously in mammals. The activity was found to be attributable to two main isoforms, calpain I and II, that differ in their calcium requirements *in vitro*. These two heterodimeric isoforms share an identical small (30k) subunit, but have distinct large (80k) subunits.

Calpains are involved in cell mobility, cell cycle progression, potentiation in neurons and cell fusion in myoblasts. When defective, the mammalian calpain 3 (p94) is the gene product responsible for limb-girdle muscular dystrophy. Calpain 10 has been identified as a susceptibility gene for type 2 diabetes mellitus, and calpain 9 has been identified as a tumor suppressor for gastric cancer. Hyperactivity of calpain is implicated in Alzheimer’s disease, cataract formation, myocardial ischemia, and in cerebral ischemia.

Increase in concentration of calcium in the cell results in calpain activation, which leads to unregulated proteolysis and consequent irreversible tissue damage. This can lead to degradation of the cytoskeleton and plasma membrane. Upon reperfusion of the ischemic myocardium, there is development of calcium overload or excess in the heart cell (cardiomyocytes). This increase in calcium leads to activation of calpain.

The endogenous calpain-specific inhibitor is called **calpastatin**. It is also involved in the proteolysis of amyloid precursor protein. The calpain/calpastatin system is involved in membrane fusion events, such as neural vesicle exocytosis and platelet aggregation.

### Calcium in blood

1. **Normal blood level**: Normal calcium level is 9-11 mg/dl (10 mg/dl of Ca\(^{++}\) = 5 mEq/L).
ii. **Ionized calcium:** About 5 mg/dl of calcium is in ionized form and is metabolically active (Fig. 35.4). Another 1 mg/dl is complexed with phosphate, bicarbonate and citrate. These two forms are diffusible from blood to tissues.

iii. **Protein bound calcium:** About 4 mg/dl of calcium is bound to proteins in blood and is nondiffusible.

**Factors Regulating Blood Calcium Level**

There are effective controls to maintain this narrow range of blood calcium (9-11 mg/dl).

**A. Vitamin D**

i. Structure of vitamin D, causes for vitamin D deficiency and clinical features of rickets are described in detail in Chapter 33. Cholecalciferol is synthesized from 7-dehydrocholesterol in skin, under the influence of sunlight. It is then hydroxylated at 25th position in liver and further hydroxylated at the 1st position in kidney. The active derivative is called dihydroxy-cholecalciferol or calcitriol. Calcitriol and calcitonin are different (Box 35.3).

ii. **Vitamin D and absorption of calcium:** Calcitriol promotes the absorption of calcium and phosphorus from the intestine. Calcitriol enters the intestinal cell and binds to a cytoplasmic receptor. The hormone-receptor complex interacts with DNA and causes derepression and consequent transcription of specific genes that code for Calbindin (Fig. 35.1). Due to the increased availability of calcium binding protein, the absorption of calcium is increased. Hence blood calcium level tends to be elevated.

iii. **Vitamin D and bone:** Vitamin D is acting independently on bone. Vitamin D increases the number and activity of osteoblasts, the bone forming cells. Calcitriol stimulates osteoblasts to secrete alkaline phosphatase.

**B. Parathyroid Hormone (PTH)**

i. This hormone is secreted by the four parathyroid glands embedded in the thyroid tissue. The chief cells of the gland secrete the PTH.

ii. It is synthesized as prepro-PTH with 115 amino acids. In the endoplasmic reticulum and in the Golgi apparatus, the prepro-PTH is broken to form the mature PTH with 84 amino acids. Storage of PTH is only for about 1 hour. This may be compared with the storage of insulin for several days and thyroxine for several weeks.

iii. The first 35 amino acids of PTH are biologically active. Control of release of the hormone is by negative feedback by the ionized calcium in serum. The release of hormone is mediated by cyclic AMP.

iv. The normal PTH level in serum is 10-60 ng/L. In primary hyperparathyroidism, this is increased to 100 ng/L

**Mechanism of Action of PTH**

i. PTH binds with a receptor protein (Mol. wt. 70,000 Daltons) on the surface of target cells. This activates adenylyl cyclase with consequent increase in intracellular calcium concentration. A kinase is activated and enzyme systems are activated. The PTH has three major independent sites of action; bone,
kidney and intestines. All the three actions of PTH increase serum calcium level.

**ii. PTH and bones:** In the bone, PTH causes demineralization or decalcification (Fig. 35.5). It induces pyrophosphatase in the osteoclasts. The numbers of osteoclasts are also increased. Osteoclasts release lactate into surrounding medium which solubilizes calcium. PTH also causes secretion of collagenase from osteoclasts. This causes loss of matrix and bone resorption. As a consequence, mucopolysaccharides and hydroxyproline are excreted in urine.

**iii. PTH and kidney:** In kidney, PTH causes decreased renal excretion of calcium and increased excretion of phosphates. The action is mainly through increase in reabsorption of calcium from kidney tubules.

**iv. PTH and intestines:** PTH stimulates 1-hydroxylation of 25-hydroxycholecalciferol in kidney to produce calcitriol. This indirectly increases calcium absorption from intestine.

**Calcium Sensing Receptor (CaSR)**
CaSR controls parathyroid hormone secretion and renal calcium reabsorption. Inactivating mutations of the CaSR result in conditions characterized by hypercalcemia and hypocalciuria, whereas activating lesions cause hypoparathyroidism and hypercalcia.

**C. Calcitonin**

i. It is secreted by the thyroid parafollicular or clear cells. Calcitonin and calcitriol are different (Box 35.3). Calcitonin is a polypeptide with 32 to 34 amino acids, depending on the species difference.

ii. Calcitonin secretion is stimulated by serum calcium, gastrin, glucagon and biological amines.

iii. Calcitonin level is increased in medullary carcinoma of thyroid and therefore, is a tumor marker. The level is also increased in multiple endocrine neoplasia (MEN). Hypercalcitoninemia may also result from ectopic calcitonin production from malignant tumors of the lung and bronchus.

iv. Calcitonin decreases serum calcium level. It inhibits resorption of bone. It decreases the activity of osteoclasts and increases that of osteoblasts.

v. Calcitonin and PTH are directly antagonistic. The PTH and calcitonin together promote the bone growth and remodelling. In kidney, calcitonin increases phosphorus excretion through urine; this action is similar to PTH (Table 35.1).

**Calcitonin, Calcitriol and PTH Act Together**

When blood calcium tends to lower, PTH secretion is stimulated and calcitonin is inhibited; bone demineralization leads to entry of more calcium into blood. When blood calcium is increased, PTH is inhibited and calcitonin is secreted, causing more entry of calcium into bone. These effects are summarized in Figure 35.5 and Table 35.1. Bone acts as the major reservoir of calcium.
D. Phosphorus

There is a reciprocal relationship of calcium with phosphorus. The ionic product of calcium and phosphorus in serum is kept as a constant. (In normal adults, calcium = 10 mg/dl x phosphorus 4 mg/dl; so ionic product is 40). In renal insufficiency, phosphorus excretion is diminished; phosphorus level in blood is increased and calcium level is lowered. This may lead to tetany.

E. Children

In children, the calcium level tends to be near the upper limit. In children, ionic product of calcium and phosphorus in blood is about 50 (instead of 40 in normal adults).

F. Serum Proteins

In hypoalbuminemia (e.g. nephrosis, malnutrition), the total calcium is decreased. About 0.8 mg/dl of calcium is reduced with lowering of each g/dl of albumin. In such cases, the metabolically active ionized form is normal, and so there will be no deficiency manifestations.

Box 35.5. Causes of Hypercalcemia

1. Hyperparathyroidism
2. Multiple myeloma
3. Paget’s disease
4. Metastatic carcinoma of bone
5. Thyrotoxicosis, Addison’s disease
6. Benign familial hypercalcemia
7. Dehydration
8. Prolonged immobilization
9. Tuberculosis, leprosy, sarcoidosis
10. Milk-alkali syndrome
11. Drugs
   - Thiazide diuretics
   - Excess vitamin D or vitamin A
   - Excess calcium given IV
   - Lithium therapy
   - Theophylline

G. Alkalosis and Acidosis

Alkalosis favors binding of more calcium with proteins, with consequent lowering of ionized calcium. Here total calcium level is normal, but calcium deficiency may be manifested. Acidosis favors ionization of calcium.

H. Kidney Threshold

The renal threshold for calcium in blood is 10 mg/dl. Calcium starts getting excreted in urine when this level is reached. When injected intravenously, most of the calcium is rapidly excreted.

Hypercaclemia

i. The term denotes that the plasma calcium level is more than 11 mg/dl. The calcium level should be tested in suspected clinical conditions (Box 35.4). The major cause is hyperparathyroidism. This may be due to a parathyroid adenoma or an ectopic PTH secreting tumor. Important causes of hypercalcemia are enumerated in Box 35.5.

ii. There is osteoporosis and X-ray shows punched out areas of bone resorption. Pathological fracture of bone may result. Box 35.6 gives major symptoms of hypercalcemia.

iii. In the blood, calcium is elevated, alkaline phosphatase levels may be increased, but phosphate level is decreased.

Box 35.7. Management of Hypercalcemia

Adequate hydration, IV normal saline
Furosemide IV to promote calcium excretion
Steroids, if there is calcitriol excess
Definitive treatment for the underlying disorder
### Box 35.8. Causes of Hypocalcemia

1. **Deficiency of Vitamin D**  
   - Decreased exposure to sunlight  
   - Malabsorption, dietary deficiency  
   - Hepatic diseases  
   - Decreased renal synthesis of calcitriol  
   - Nephrotic syndrome (binding protein lost)  
   - Anticonvulsant therapy

2. **Deficiency of Parathyroid**  
   - Hypoparathyroidism (primary, secondary)  
   - Pseudohypoparathyroidism

3. **Increased Calcitonin**  
   - Medullary carcinoma of thyroid

4. **Deficiency of Calcium**  
   - Intestinal malabsorption  
   - Acute pancreatitis  
   - Infusion of agents complexing calcium  
   - Alkalosis decreasing ionized calcium

5. **Deficiency of Magnesium**

6. **Increase in Phosphorus Level**  
   - Renal failure  
   - Phosphate infusion  
   - Renal tubular acidosis

7. **Hypoalbuminemia**

### Parathyroid Function Tests

1. Estimation of serum calcium, phosphate and alkaline phosphatase.
2. Urinary calcium and phosphate levels.

### Box 35.9. Symptoms of Hypocalcemia

1. Muscle cramps  
2. Paresthesia, especially in fingers  
3. Neuromuscular irritability, muscle twitchings  
4. Tetany (Chvostek’s sign, Trousseau’s sign)  
5. Seizures  
6. Bradycardia  
7. Prolonged QT interval

### Hypocalcemia

#### A. Tetany

i. Causes of hypocalcemia are enumerated in Box 35.8. When serum calcium level is less than 8.8 mg/dl, it is hypocalcemia. If serum calcium level is less than 8.5 mg/dl, there will be mild tremors. If it is lower than 7.5 mg/dl, tetany, a life-threatening condition will result. Symptoms of hypocalcemia are enumerated in Box 35.9.

ii. **Tetany** may be due to accidental surgical removal of parathyroid glands or by autoimmune diseases. In tetany, neuromuscular irritability is increased.

iii. Main manifestation is carpopedal spasm (Fig. 35.6). Laryngismus and stridor are associated findings. Laryngeal spasm may lead to death. **Chvostek’s sign** (tapping over facial nerve causes facial contraction) will be positive (described by Frantisek Chvostek, Czech physician in 1876). **Trousseau's sign** (inflation of BP cuff for 3 minutes causes carpopedal spasm) could be elicited (French physician Armand Trousseau described it in 1861).

iv. Increased Q-T interval in ECG is seen. Serum calcium is lowered with corresponding increase in phosphate level. Urinary excretion of both calcium and phosphate are decreased. Treatment is to give intravenous injection of calcium salts.
v. It should be emphasized that vitamin D deficiency will not cause tetany. The vitamin D deficiency causes rickets, where serum calcium level is lowered marginally. Treatment policy of hypocalcemia is shown in Box 35.10.

B. Pseudohypoparathyroidism
It is an X-linked dominant condition. Although PTH level is normal, there is lack of end organ response to PTH. This leads to hypocalcemia and hyperphosphatemia.

C. Mild decrease in serum calcium
Vitamin D insufficiency, renal diseases (defective formation of calcitriol), dietary deficiency of calcium, and magnesium deficiency will result in mild decrease in serum calcium. Chronic calcium deficiency will lead to deformities of bones, especially in weight bearing bones (Fig. 35.7A).

Bone Mineralization and Demineralization
Bone is a specialized connective tissue made up of a matrix with embedded fibers, cells and apatite crystals (Fig. 35.7B). See Box 35.11 for the requirement for bone production.

Mineralization of bone: It is the process by which inorganic calcium and phosphate are deposited on the organic matrix. The specialized matrix in bone is termed osteoid. In cementum, the matrix is called cementoid. In dentine, the equivalent layer is known as predentine. In enamel, there is no equivalent, since the matrix is rapidly calcified. Osteocalcin is a unique protein seen in bone. Osteocalcin, osteonectin, osteopontin and osteoprotegerin are described in Chapter 48. The osteoblasts synthesize and secrete organic matrix, which is then mineralized. Osteoclasts are involved in bone resorption. Combined activities of osteoblasts and osteoclasts are important in bone remodelling. The osteoblasts are under the effect of hormones PTH and calcitriol. Secretion of alkaline phosphatase by osteoblasts is increased by vitamin D. The enzyme liberates phosphate from substrates. So the ionic concentration of \([\text{calcium} \times \text{phosphate}]\) is increased to supersaturation level. Calcium phosphate is deposited as hydroxyapatite crystals over the matrix of triple stranded quarter staggered collagen molecules (see Chapter 52). Calcium in the bone is in dynamic equilibrium with serum calcium; hydroxyapatite in trabecular bone acts as a reservoir.

Compact bone \(\rightarrow\) Trabecular bone \(\leftrightarrow\) Serum calcium
\[
\begin{align*}
\text{Ca}_3(\text{PO}_4)_2 & \quad \text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2 \\
(\text{Total 1 kg}) & \quad (\text{Total about 5 g}) & \quad (\text{Total 500 mg})
\end{align*}
\]

**Box 35.10. Treatment of Hypocalcemia**

1. Oral calcium, with vitamin D supplementation
2. Underlying cause should be treated
3. Tetany needs IV calcium (usually 10 ml 10% calcium gluconate over 10 minutes, followed by slow IV infusion. IV calcium should be given only very slowly.

Osteoporosis
Most prevalent metabolic bone disease that is associated with an increased risk for fractures (vertebra, hip and forearm). Women above 50 years of age have a 40% risk for these fractures. The basic abnormality is decrease in bone mass, which attains a peak by the age of 30 and starts declining by 35 to 45 years of age in both men and women. After the age of 40-45, calcium absorption is reduced and calcium excretion is increased; so, there is a net negative balance for calcium. This is reflected in demineralization (Fig. 35.7B). Decreased absorption of vitamin D and reduced levels of androgens/estrogens in old age are the causative factors. Interleukin-1 and 6 also play important roles in the genesis of the condition. Osteoporosis is more severe and starts early in Indians, compared to Westerners.

Osteopetrosis
It is otherwise called marble bone disease. There is increased bone density. It is due to mutation in gene encoding carbonic anhydrase type II. The deficiency of the enzyme in osteoclasts leads to inability of bone resorption.

Paget's disease
Localized disease of bone characterized by osteoclastic bone resorption followed by disordered replacement of bone. It is common in people above 40 and may affect one or several bones. Familial incidence is also reported. Bone markers are useful in monitoring response to treatment using bisphosphonates.

Renal osteodystrophy
Secondary hyperparathyroidism as a consequence of persistent hypocalcemia causes high turn over bone disease, osteitis fibrosa. Osteomalacia may result (low born turnover) due to defective synthesis of 1,25 DHCC.

**Box 35.11. Requirements for Growth of Bone**

1. Calcium
2. Phosphorus
3. Vitamin D and calcitriol
4. Parathyroid hormone
5. Calcitonin
6. Vitamin A (for ground substance)
7. Vitamin C
8. Sex steroids

Figs 35.7A and B. (A) Knock-knee defect in deficiency of calcium and phosphorus. (B) Comparison of normal and osteoporotic bone tissue
Markers of bone diseases

The markers of bone diseases are mainly used in monitoring the response to treatment.

1. General markers

Serum calcium, serum inorganic phosphorus, serum magnesium and urinary excretion of calcium and phosphorus, total alkaline phosphatase and total acid phosphatase levels. These are the routine tests of bone metabolism.

2. Markers of bone resorption

Telopeptides and pyridinium cross links derived from collagen, tartrate resistant acid phosphatase (TRAP), urinary hydroxyproline excretion, serum carboxy terminal telopeptide of type I collagen (s-CTX) and N-telopeptide of type 1 collagen (NTX).

Type I collagen forms 90% of the organic matrix of the bone. These markers originate as breakdown products of mature matrix collagen. Telopeptides and pyridinium cross links are released into circulation. Effective treatment decreases their level. Major source of hydroxyproline in urine is collagen breakdown.

Serum TRAP exists in the two isoforms 5a and 5b with only 5b being specific for osteoclasts. TRAP 5b might be an indicator of bone resorption in a very early stage of renal osteodystrophy.

3. Markers of bone formation

Serum bone specific isoenzyme of alkaline phosphatase (sBAP), serum osteocalcin (s-OC), serum midportion of osteocalcin (sm-OC), procollagen type 1 peptidase, serum intact osteocalcin (s-OC) and serum amino terminal propeptide of type I collagen (PINP).

BAP is increased in metabolic bone diseases. Advantages over osteocalcin is that clinically it is more specific and sensitive in monitoring diseases, especially Paget’s disease.

Osteocalcin is the major noncollagen protein in human bone. It has 49 amino acids and forming about 1% of total protein in bones. During bone formation 10-30% of osteocalcin synthesized is released into circulation. In metabolic bone diseases with increased osteoid formation it is increased.

Procollagen peptidase that cleaves peptides from collagen during maturation can also be used as a marker, though less specific and sensitive.

PHOSPHORUS

Total body phosphate is about 1 kg; 80% of which is seen in bone and teeth and 10% in muscles. Phosphate is mainly an intracellular ion and is seen in all cells. Functions of phosphate ions are enumerated in Box 35.12.

Requirement and Source

Requirement is about 500 mg/day. Milk is a good source, which contains about 100 mg/dl of phosphates. Cereals, nuts and meat are moderate sources. Calcitriol increases phosphate absorption.

Serum Level of Phosphorus

Serum level of phosphate is 3-4 mg/dl in normal adults and is 5-6 mg/dl in children. Fasting levels are higher. The postprandial decrease of phosphorus is due to the utilization of phosphate for metabolism. Monovalent and divalent phosphate ions are present in plasma at a ratio of 1:9 in alkalosis, at a ratio of 1:4 at pH 7.4, and at a ratio of 100:1 at pH of 4.5 in urine.

The whole blood phosphate is 40 mg/dl. This is because RBCs and WBCs contain a lot of phosphates. Hemolysis should be prevented when blood is taken for phosphate estimation.

Serum phosphate level is decreased in hyperparathyroidism and rickets. Box 35.13 shows the conditions in which phosphate level is to be assessed. Causes of hyperphosphatemia are given in Box 35.14, and those of hypophosphatemia in Box 35.15. Box 35.16 enumerates the conditions in which alterations of calcium and phosphate levels.

Phosphorus holds an inverse relationship with calcium. An excess of serum calcium or phosphate results in the excretion of the other by the kidney. The phosphate level is regulated by excretion through urine. Renal threshold is 2 mg/dl. Usually 500 mg of phosphate is excreted through urine per day. Urinary phosphate excretion is influenced by many factors including muscle mass, renal function and age. A diurnal variation in urine phosphate excretion has been noted, with the highest output occurring in the afternoon.

Like calcium, phosphate level in blood is controlled by the parathyroid hormone. PTH increases calcium and phosphate release from the bone and decreases loss of calcium and increases loss of phosphate in the urine.

Box 35.12. Functions of Phosphate Ions

1. Formation of bone and teeth.
2. Production of high energy phosphate compounds such as ATP, CTP, GTP, creatine phosphate, etc.
3. Synthesis of nucleoside co-enzymes such as NAD and NADP.
4. DNA and RNA synthesis, where phosphodiester linkages form the backbone of the structure.
5. Formation of phosphate esters such as glucose-6-phosphate, phospholipids.
6. Formation of phosphoproteins, e.g. casein.
7. Activation of enzymes by phosphorylation.
8. Phosphate buffer system in blood. The ratio of \( \text{Na}_3\text{HPO}_4 : \text{NaH}_2\text{PO}_4 \) in blood is 4:1 at pH of 7.4.

Box 35.13. Phosphate Level is to be Checked When There is Suspicion of

1. Renal tubular disease
2. Hyperparathyroidism
3. Hypoparathyroidism
4. Bone diseases, such as rickets
5. Muscle weakness
6. Renal failure
Box 35.14. Causes of Hyperphosphatemia

1. Increased absorption of phosphate
   - Excess vitamin D
   - Phosphate infusion
2. Increased cell lysis
   - Chemotherapy for cancer
   - Bone secondaries
   - Rhabdomyolysis
3. Decreased excretion of phosphorus
   - Renal impairment
   - Hypoparathyroidism
4. Hypocalcemia
5. Massive blood transfusions
6. Thyrotoxicosis
7. Drugs
   - Chlorothiazide, Nifedipine, Furosemide

Box 35.15. Causes of Hypophosphatemia

1. Decreased absorption of phosphate
   - Malnutrition
   - Malabsorption
   - Chronic diarrhea
   - Vitamin D deficiency
2. Intracellular shift
   - Insulin therapy, glucose phosphorylation
   - Respiratory alkalosis
3. Increased urinary excretion of phosphate
   - Hyperparathyroidism
   - Fanconi's syndrome
   - Hypophosphatemic rickets
4. Hereditary hypophosphatemia
5. Hypercalcemia
6. Chronic alcoholism
7. Drugs
   - Antacids, Diuretics, Salicylate intoxication

Box 35.16. Important Combinations of Serum Calcium and Phosphate Levels in Blood

1. Increased P with decreased Ca
   - Hypoparathyroidism
   - Renal disease
2. Increased P with normal or increased Ca
   - Milk alkali syndrome
   - Hypervitaminosis D
3. Decreased P with increased Ca
   - Hyperparathyroidism
   - Sarcoidosis
4. Decreased P and Ca
   - Malabsorption
   - Vitamin D deficiency
   - Renal tubular acidosis

Fibroblast Growth Factor 23 (FGF-23)
It acts on the kidney to inhibit the reabsorption of phosphate and the synthesis of 1,25(OH)2D. Disorders of increased FGF-23 function are associated with hypophosphatemia, inappropriately low 1,25(OH)2D levels, and either rickets or osteomalacia. Conversely, decreased FGF-23 activity results in hyperphosphatemia, increased 1,25(OH)2D levels, and abnormal soft-tissue calcification. Increase in FGF-23 is being investigated as a marker of disease progression in chronic kidney disease.

MAGNESIUM (Mg++)
Magnesium is the fourth most abundant cation in the body and second most prevalent intracellular cation. Magnesium is mainly seen in intracellular fluid. Total body magnesium is about 25 g, 60% of which is complexed with calcium in bone.
Chapter 35; Mineral Metabolism and Abnormalities

**Box 35.17. When to Test for Magnesium?**

1. Cardiac arrhythmia
2. Resistant hypokalemia
3. Pregnancy with pre-eclampsia
4. Tetany not responding to calcium therapy

Liver cirrhosis, protein-calorie malnutrition and diuretic therapy are the common causes (see Box 35.18). Urinary loss can occur in alcoholism, osmotic diuretics, loop diuretics and aminoglycosides. Serum magnesium levels need not always reflect body content. Measurement of urinary magnesium excretion will distinguish between renal and gastrointestinal losses.

Deficiency of magnesium leads to neuromuscular hyperirritability and cardiac arrhythmias. The magnesium deficiency symptoms are similar to those of calcium deficiency; but symptoms will be relieved only when magnesium is given. Acute symptomatic deficiency is treated by giving parenteral magnesium. Oral therapy may lead to diarrhea, hence intravenous magnesium sulfate is given.

**Box 35.18. Causes of Hypomagnesemia**

1. Increased urinary loss (Tubular necrosis)
2. Hyperaldosteronism, volume expansion
3. Familial hypomagnesemia
4. Increased intestinal loss
   - Diarrhea, laxatives, ulcerative colitis
   - Nasogastric suction, vomiting
5. Liver cirrhosis
6. Malabsorption
7. Protein calorie malnutrition
8. Hypoparathyroidism
9. Toxemia of pregnancy
10. Drugs: Thiazide diuretics
    - Aminoglycosides
    - Cisplatin
    - Amphotericin
    - Cyclosporin
    - Haloperidol
    - Alcohol

**Box 35.19. Causes of Hypermagnesemia**

1. Excess intake orally or parenterally
2. Renal failure
3. Hyperparathyroidism
4. Oxalate poisoning
5. Rickets
6. Multiple myeloma
7. Dehydration
8. Drugs: Aminoglycosides
   - Antacids
   - Calcitriol
   - Tacrolimus

**SULFUR**

Source of sulfates is mainly amino acids cysteine and methionine. Proteins contain about 1% sulfur by weight. Inorganic sulfates of Na⁺, K⁺ and Mg²⁺, though available in food, are not utilized.

**Functions of Sulfur**

1. Sulfur containing amino acids are important constituents of body proteins. The disulfide bridges keep polypeptide units together, e.g. insulin, immunoglobulins.
2. Chondroitin sulfates are seen in cartilage and bone.
3. Keratin is rich in sulfur, and is present in hair and nail.
4. Many enzymes and peptides contain -SH group at the active site, e.g. glutathione.
5. Co-enzymes derived from thiamine, biotin, pantothenic acid and lipoic acid also contain sulfur.
6. If sulfate is to be introduced in glycosaminoglycans or in phenols for detoxification, it can be done only by phosphoadenosine phosphosulfate (PAPS).
7. Sulfates are also important in detoxification mechanisms, e.g. production of indoxyl sulphate.

**Excretion**

All the sulfur groups are ultimately oxidized in liver to sulfate (SO₄²⁻) group and excreted in urine. The total quantity of sulfur in urine is about 1 gm/day. This contains 3 categories.

i. **Inorganic sulfates**: It is about 80% of the total excretion. This is proportional to the protein intake. This category can be isolated by treating the urine with barium chloride, when white barium sulfate is precipitated.

ii. **Organic sulfate or ethereal sulfate**: It is also called conjugated sulfate. It constitutes 10% of urinary sulfates. Tryptophan is converted to phenol and indoxyl by intestinal bacteria. These are absorbed and conjugated with sulfates and excreted through urine. Therefore, this represents the putrefactive activity in intestine, and this fraction is increased in intestinal stasis. This part is also proportional to protein intake. This fraction will not give a direct precipitate with barium chloride. Urine is boiled with HCl and BaCl₂ is added to produce white precipitate of barium sulfate.
iii. Neutral sulfur or unoxidized sulfur:
This fraction constitutes 10% of total sulfates. Sulfur containing organic compounds such as amino acids, thiocyanates and urochrome constitute this fraction. This will not vary with diet. In obstructive jaundice, taurocholic acid is excreted in urine, and hence this fraction is increased. It is also increased in amino acidurias.

IRON (Fe)

Distribution of iron
Total body iron content is 3 to 5 gm; 75% of which is in blood, the rest is in liver, bone marrow and muscles. Iron is present in almost all cells. Heme containing proteins are shown in Table 35.2.

Blood contains 14.5 g of Hb per 100 ml. About 75% of total iron is in hemoglobin, and 5% is in myoglobin and 15% in ferritin. Normal iron kinetics is shown in Figure 35.8.

Requirement of Iron (ICMR)

i. Daily allowance of iron for an adult Indian is 20 mg, out of which about 1-2 mg is absorbed. In Western countries, requirement is less (15 mg/day) because the diet does not contain inhibitory substances.

ii. Children between 13-15 years need 20-30 mg/day.

iii. Pregnant women need 40 mg/day. Transfer of iron and calcium from mother to fetus occurs mainly in the last trimester of pregnancy. Therefore, during this period mother’s food should contain surplus quantities of iron and calcium.

iv. In the first 3 months of life, iron intake is negligible because milk is a poor source of iron. During this time, child is dependent on the iron reserve received from mother during pregnancy. In premature babies, the transplacental transfer of iron might not have taken place. Hence such babies are at a risk of iron deficiency. After 3 months of life, diet supplementation with cereals is essential for supplying the iron requirement.

Sources of Iron

i. **Leafy vegetables** (20 mg/100 g) are good sources. Pulses (10 mg/100 g) and cereals (5 mg/100 g) contain lesser quantity of iron. In a typical Indian diet, the major quantity of iron is received from cereals because of the bulk quantity taken, although they contain iron only in moderate amounts.

ii. Liver (5 mg/100 g) and meat (2 mg/100 g)

iii. **Jaggery** is a good source of iron.

iv. Cooking in iron utensils will improve the iron content of the diet.

v. Milk is a **very poor source** of iron, containing less than 0.1 mg/100 ml.

Factors Influencing Absorption of Iron

Iron is absorbed by upper part of duodenum. The following factors affect this absorption of iron:

A. **Reduced form of iron**
Only Fe²⁺ (**ferrous**) form (reduced form) is absorbed. Fe³⁺ (**ferric**) form is not absorbed.

B. **Ascorbic acid**
Ferric ions are reduced with the help of gastric HCl; ascorbic acid, cysteine and -SH groups of proteins.
Therefore, these will favor iron absorption. About 50-75 mg of ascorbic acid per day will be sufficient for normal iron absorption.

C. Interfering substances
Iron absorption is decreased by phytic acid (in cereals) and oxalic acid (in leafy vegetables) by forming insoluble iron salts. An average Indian diet contains more than 20 mg of iron. But the phytates and oxalates in the diet reduce the absorption, and only about 1 mg of iron is absorbed. In Western diet, even though iron content is about 10 mg, about 2 mg is absorbed.

D. Other minerals
Calcium, copper, lead and phosphates will inhibit iron absorption. One atom of lead will inhibit absorption of 1000 atoms of iron. A glass of milk, which contains calcium will appreciably reduce iron absorption.

E. Mucosal Block Theory
i. Duodenum and jejunum are the sites of absorption. Iron metabolism is unique because homeostasis is maintained by regulation at the level of absorption and not by excretion (Fig. 35.9). No other nutrient is regulated in this manner. In other words, iron is a one-way element.

ii. When iron stores in the body are depleted, absorption is enhanced. When adequate quantity of iron is stored, absorption is decreased. This is referred to as mucosal block of regulation of absorption of iron.

iii. Only ferrous (and not ferric) form of iron is absorbed. Ferric iron is reduced to ferrous iron by ferric reductase, an enzyme present on the surface of enterocytes. Ferrous iron in the intestinal lumen binds to mucosal cell protein, called divalent metal transporter-1 (DMT-1). This bound iron is then transported into the mucosal cell. The rest of the unabsorbed iron is excreted (Fig. 35.9).

iv. Inside the mucosal cell, the ferric iron is formed and is complexed with apoferritin to form ferritin. It is kept temporarily in the mucosal cell. If there is anemia, the iron is further absorbed into the bloodstream. If transferrin is saturated with iron, any iron accumulated in the mucosal cell is lost when the cell is desquamated. The fraction of iron absorbed and retained is decided by the iron status. When iron is in excess, absorption is reduced; this is the basis of "mucosal block" (Fig. 35.9).

v. This mechanism of iron absorption from intestinal lumen to the mucosal cell is different from the iron release from intestinal cell to the bloodstream (Fig. 35.9). Iron in the ferritin is released, then crosses the mucosal cell with the help of a transport protein called, ferroportin. But this can happen only when there is free transferrin in plasma to bind the iron. Iron crosses the cell membrane as ferrous form. In the blood it is re-oxidized to ferric state, and transported by transferrin.
F. Regulation of absorption by 4 mechanisms

i. Mucosal regulation: Regulation by mucosal block, as explained above. Absorption of iron needs divalent metal ion transporter and ferroportin. Synthesis of both these proteins is downregulated by hepcidin, a peptide secreted by the liver when body iron reserves are adequate. If there is hypoxia or anemia, the synthesis of hepcidin is reduced; so ferroportin synthesis will increase.

Hepcidin is identified only recently in 2001. It is produced by liver cells and is involved in killing bacteria and hence the name. It is coded in HAMP gene on chromosome 19. Its main action is on iron metabolism. Hepcidin decreases surface expression of the ferroportin, which is responsible for moving iron across cell membranes. Hepcidin production is increased by high iron stores and also by inflammation.

ii. Stores regulation: As body iron stores fall, the mucosa is signalled to increase absorption.

iii. Erythropoietic regulation: In response to anemia, the erythroid cells will signal the mucosa to increase iron absorption. This signal may be erythropoietin from kidney.

iv. There is reciprocal relationship between synthesis of ferritin and transferrin receptor (TfR). In case of high concentration of iron, the iron bound to the IRE-BP (internal ribosome entry site-binding protein) prevents binding of IRE of both mRNA molecules. So, mRNA for ferritin is translated and ferritin is synthesized. But mRNA for TfR is degraded, resulting in reduced TfR protein synthesis. Thus, when iron levels are high, ferritin is synthesized to store iron. At the same time, there is no requirement for further uptake of iron, so the TfR is not synthesized. This is a good example of control of protein synthesis at the translational level.

Iron Transport in Blood and Uptake by Cells

i. Transport form of iron is transferrin. It is a glycoprotein, beta-1 globulin, with molecular weight of 76,500 Daltons. It is synthesized in liver.

ii. Normal plasma level of transferrin is 250 mg/100 ml. In iron deficiency, this level is increased. One molecule of transferrin can transport 2 ferric atoms. About 20 polymorphic forms of transferrin are seen in population.

iii. Total iron binding capacity (TIBC) in plasma is 400 mg/100 ml; this is provided by the transferrin. One-third of this capacity is saturated with iron. This protein bound iron (serum iron) is about 120 mg/dl.

iv. Abnormalities in these parameters are shown in Table 35.3. In iron deficiency anemia, TIBC is increased (transferrin level is increased); but serum iron level is reduced. Transferrin has a half-life of 7-10 days, and is a useful index of nutritional status. One molecule of transferrin can bind two ferric ions.

v. In blood, ceruloplasmin is the ferroxidase, which oxidizes ferrous to ferric state (Fig. 35.12).

Ferroxidase
Apo-transferrin $\rightarrow$ Transferrin combined $\rightarrow$ + 2 Fe$^{++}$ with 2 Fe$^{+++}$

vi. Transferrin receptors (TfR) are present on most of the body cells, especially on cells which synthesize heme. The iron-transferrin complex is taken up by the body cells by the receptor mechanism. The transferrin receptor has a molecular weight of 200 kD. It binds two molecules of transferrin. The iron-transferrin-receptor is internalized. Iron is taken in by the cells, and receptor molecules are externalized.

vii. Transferrin is a glycoprotein. Abnormal glycosylation is seen in congenital disorders and in chronic alcohol abuse.

Storage of Iron

i. The storage form is ferritin. It is seen in intestinal mucosal cells, liver, spleen and bone marrow.

ii. The apoferritin has a molecular weight of about 440 kilo Daltons. It has 24 subunits. It can take up to 4,000 iron atoms per molecule. Ferritin contains about 23% iron.

iii. Normal plasma contains very little ferritin. Ferritin in plasma is elevated in iron overload. Thus ferritin level in blood is an index of body iron stores.

iv. Ferritin is an acute phase reactant protein that is elevated in inflammatory diseases. Estimation of ferritin is also indicated in chronic kidney disease to assess the extent of anemia.

v. Synthesis of TfR and ferritin and that of ferritin are reciprocally controlled. Both are controlled by the iron content. When iron levels are high, ferritin is synthesized to store the iron; but the TfR synthesis is blocked. When iron levels are high, iron binds to iron-response-element-binding-protein (IREBP), preventing it from binding to IRE. This will result in synthesis of new ferritin, and suppression of synthesis of TfR.

vi. In iron deficiency anemia, ferritin content is reduced. When iron is given in anemia, the apoferritin production is induced within a few hours.

vii. Estimation of ferritin in chronic kidney disease (CKD) is of prognostic significance since ferritin level less than 100 microgram/dl indicates iron deficiency. Transferrin saturation less than 20% and ferritin between 100 and 200 microgram/dl is suggestive of functional deficiency. In order to treat the anemia in CKD, the iron stores should be adequate and this is denoted by serial ferritin estimations in a patient on treatment to check the efficacy of treatment with recombinant erythropoietin (epoetin).

viii. Ageing cells will release iron with the help of a copper containing protein called hephaestin, which has ferroxidase activity (similar to ceruloplasmin).

ix. Hemosiderin is also a storage form of iron, but it is formed by partial deproteinization of ferritin by lysosomes and are found as aggregates in tissues like liver, spleen and bone marrow. It is more insoluble than ferritin, and iron is more slowly released.

Iron is Conserved

i. When RBCs are lysed, hemoglobin enters the circulation. Being a small molecular weight substance, Hb will be lost through urine. To prevent this loss, Hb is immediately taken up by haptoglobin (Hp) (Fig. 35.10). Hb-Hp complex is taken up by macrophage system, such as Kupffer cells.

ii. It is an alpha-2 globulin. It has 2 light and 2 heavy chains. Normal level of Hp is 40-175 mg/dl. Normal half-life of Hp is 5 days; but Hb-Hp complex has only 90 minutes. So, when there is hemolysis, there is rapid turnover of Hp and hence Hp level in blood is decreased. Hp is an acute phase protein, and the level is increased in inflammations.

iii. Haptoglobin exists in 3 polymorphic forms; Hp1-1, Hp2-1 and Hp2-2. Two genes will separately synthesize the two different polypeptides and they will combine to form these 3 forms. Hp1-1 has a molecular weight of 90 kD.

iv. Haptoglobin-related protein (HRP) bears a high degree of amino acid homology to haptoglobin. HRP also binds hemoglobin.

v. When the globin part is removed from Hb, the heme is produced, and is released into circulation. In order to prevent its excretion through urine, heme is bound with hemopexin (Fig. 35.10).

vi. Hemopexin is a beta-globulin with a molecular weight of 57,000 daltons. Normal blood level is 50-100 mg/dl, which is increased during hemolysis.

vii. Iron is a very rare element in the universe. The temperature and pressure inside the sun are not enough to create iron atoms, which require supernova explosions. Iron generated by such rare cosmological events should then be condensed to planetary systems. Even in earth, 99%
of iron is trapped inside the deep core. The surface of earth contains comparatively little iron. Moreover, the solubility of iron in the universal solvent, water, is negligible. For all these reasons, iron is very precious for biological systems. Hence these elaborate mechanisms are necessary for conservation inside the body (Fig. 35.10).

Excretion of Iron

i. Iron is a one-way element. That is, very little of it is excreted. The regulation of homeostasis is done at the absorption level.

ii. Any type of bleeding will cause loss of iron from the body. Menstrual flow is the major cause for loss of iron in women. Women up to menopause will lose iron at a rate of about 1 mg/day. The loss in male is less than 0.5 mg/day.

iii. Almost no iron is excreted through urine. Feces contain unabsorbed iron as well as iron trapped in the intestinal cells, which are then desquamated. About 30% of cells in the intestinal lining are replenished every day, and so this loss is considerable.

iv. All the cells in skin contain iron. The upper layers of skin cells are constantly being lost, and this is another route for iron loss from the body.

Iron Deficiency Anemia

It is the most common nutritional deficiency disease. About 30% of world population is anemic. All over India, this is about 70%. 85% of pregnant women suffer from anemia. Maternal anemia contributes to increase in perinatal mortality. Anemia often leads to irreversible impairment of child’s learning ability.

Excretion of Iron

iv. All the cells in skin contain iron. The upper layers of skin cells are constantly being lost, and this is another route for iron loss from the body.
respiration and all metabolic processes become sluggish.

ii. Prolonged iron deficiency causes atrophy of gastric epithelium leading to achlorhydria, which in turn causes lesser absorption of iron, aggravating the anemia. Similar atrophy of epithelium in oral cavity and esophagus causes dysphagia termed Plummer-Wilson syndrome, which is a known precancerous condition.

iii. Very chronic iron deficiency anemia will lead to impaired attention, irritability, lowered memory and poor scholastic performance. Anemia and apathy go hand in hand (Fig. 35.11B).

D. Laboratory Findings

Laboratory investigations generally used to diagnose anemias are listed in Table 35.3.

i. Serum iron level: It is depressed in iron deficiency, acute and chronic infections, carcinomas, hypothyroidism and Kwashiorkor.

ii. Total iron binding capacity (TIBC): It is elevated in hypochromic anemias, acute hepatitis and pregnancy.

iii. Soluble transferrin receptor level (TfR): It has distinct advantages over the other parameters because inflammatory states will not alter sTR levels. The level of sTR is increased in iron deficiency anemia, hemolytic anemia and polycythemia. Decreased values are seen in aplastic anemia and chronic renal failure.

E. Treatment of Iron Deficiency

Oral iron supplementation is the treatment of choice. 100 mg of iron + 500 microgram of folic acid are given to pregnant women, and 20 mg of iron + 100 microgram folic acid to children. Iron tablets are usually given along with vitamin C, to convert it into ferrous form, for easy absorption. Unabsorbed iron may generate free radicals and so, it is advisable to give vitamin E (to prevent free radical generation) along with iron.

Iron Toxicity

i. More than 50 mg of iron taken orally may cause nausea, diarrhea and abdominal pain.

ii. Hemosiderosis: Iron excess is called hemosiderosis. Hemosiderin pigments are golden brown granules, seen in spleen and liver. Prussian blue reaction is positive for these pigments. Hemosiderosis occurs in persons receiving repeated blood transfusions. Here the regulation at the level of intestine is circumvented leading to iron overload. Hemophilic children require blood transfusion every 3 months. If whole blood is given every time, by about 20 years of age, the patient will have hemosiderosis. This is the commonest cause for hemosiderosis in India.

iii. Primary hemosiderosis: It is also called hereditary hemochromatosis. The abnormal gene is located on the short arm of chromosome no. 6. In these cases, iron absorption is increased and transferrin level in serum is elevated. Excess iron deposits are seen.

iv. Iron vessels: Cooking in iron vessels increases the availability of iron.

v. Bantu siderosis: Bantu tribe in Africa is prone to hemosiderosis because the staple diet, corn, is low in phosphate content.

vi. Hemochromatosis: When total body iron is higher than 25-30 gm, hemosiderosis is manifested. In the liver, hemosiderin deposit leads to death of cells and cirrhosis. Pancreatic cell death leads to diabetes. Deposits under the skin cause yellow-brown discoloration, which is called hemochromatosis. The triad of cirrhosis, hemochromatosis and diabetes are referred to as bronze diabetes.

vii. Treatment of hemosiderosis: Repeated phlebotomy every week, till serum iron, and ferritin reach near normal levels. This may require several years. Desferroxamine, a chelating agent, forms an iron chelate with Fe+++ to form ferroxamine which is excreted in urine.

Excess iron helps bacterial! Bacteria are dependent on iron for growth which produces low molecular weight iron binding compounds. Ordinarily transferrin binds iron tightly and very little is available as free iron for bacteria to bind. But when there is excess iron or when the binding by transferrin is affected by a drop in pH, more free iron is available to the bacteria making them pathogenic. Pathogenicity induced by excess iron in certain bacteria found in oysters is said to be responsible for their lethal effect when consumed by individuals.
COPPER (Cu)

Total body copper is about 100 mg. It is seen in muscles, liver, bone marrow, brain, kidney, heart and in hair.

Copper containing enzymes are ceruloplasmin, cytochrome oxidase, cytochrome c, tyrosinase, lysyl oxidase, ALA synthase, monoamine oxidase, superoxide dismutase and phenol oxidase.

Copper containing nonenzymatic proteins are hepatocuprein in liver (storage form), cuprothionine in liver, cerebrocuprein in brain, hemocuprein in RBC and erythrocuprein in bone marrow. Hemocyanin is the oxygen carrying blue pigment seen in crustacea.

Copper requirement for an adult is 1.5-3 mg per day. Major dietary sources are cereals, meat, liver, nuts and green leafy vegetables. Milk is very poor in copper content.

Only about 10% of dietary copper is absorbed. Excretion is mainly through bile. Urine does not contain copper in normal circumstances. Whole blood contains about 100 microgram/dl of copper. Out of this, 95% is in RBC as colorless erythrocuprein. In plasma ceruloplasmin is an important copper containing protein (see Chapter 28). Normal serum level of ceruloplasmin is 25-50 mg/dl. Ceruloplasmin is a blue-colored glycoprotein (Latin "caeruleus" = blue). It is also called serum ferroxidase. It promotes oxidation of ferrous ion to ferric form, which is incorporated into transferrin (Fig. 35.12). The copper atoms are tightly bound with ceruloplasmin. So copper from ceruloplasmin cannot be released easily. About 10% of copper in plasma is loosely bound with albumin, which constitutes the transport form of copper.

Functions of Copper

1. It is necessary for iron absorption and incorporation of iron into hemoglobin.
2. It is necessary for tyrosinase activity.
3. It is a co-factor for vitamin C requiring hydroxylations.
4. It increases HDL and so protects the heart.

Abnormal Metabolism of Copper

i. Wilson's Disease: Ceruloplasmin level in blood is drastically reduced in Wilson's hepato-lenticular degeneration. The incidence of Wilson's disease is 1 in 50,000. The basic defect is in a gene encoding a copper binding ATPase in cells (ATP7B gene in liver cells). This is required for normal excretion of copper from liver cells; in its absence, copper is accumulated in cells, leading to copper deposits in liver and brain (see Chapter 28). Administration of penicillamine, which helps in chelation and excretion of copper, may help the affected persons. As zinc decreases copper absorption, zinc is sometimes used therapeutically in Wilson's disease, to reduce copper load in the body.

ii. Aceruloplasminemia: Levels of ceruloplasmin (ferroxidase activity) are congenitally low. So, iron is not utilized properly. Iron accumulates in brain, liver and pancreatic islet cells. Neurological symptoms are seen.

iii. Copper Deficiency Anemia: Copper is essential for the formation of hemoglobin. Copper containing ceruloplasmin helps in iron transport. Copper is an integral part of ALA synthase, which is the key enzyme in heme synthesis. Copper helps the uptake of iron by normoblasts. Copper deficiency is manifested as anemia. RBC count is reduced; cell size is small; but hemoglobin concentration is more or less normal. Copper deficiency thus results in microcytic normochromic anemia. If there is added iron deficiency, hypochromic anemia results.

iv. Cardiovascular Diseases: Copper is a constituent of lysyl oxidase. It oxidizes four lysine residues together to form desmosine which makes cross linkages in elastin. In copper deficiency, elastin becomes abnormal, leading to weakening of walls of major blood vessels. This favors aneurysm and fatal rupture of the wall of aorta. Another finding is the fibrosis of myocardium leading to cardiac failure.

v. Menke's Kinky Hair Syndrome: It is an X-linked defect (affects only male children). It is a condition in which dietary copper is absorbed from GI tract; but cannot be
transported to blood due to absence of an intracellular copper binding ATPase (mutation in ATP7A gene). Please note that the proteins present in liver and in extrahepatic tissues are different. This explains the difference in clinical manifestations of Wilson's disease and Menke's disease. Copper is not mobilized from intestinal cells as well as in other tissue cells. The copper that has entered into the cell is not able to get out of the cells, and so it accumulates. Hence copper is not available for metabolism, resulting in defective cross-linking of connective tissue. Vascular and connective tissues are affected, and child dies usually in infancy. Injections of copper salts may be effective as a treatment.

vi. Melanin: Copper is present in tyrosinase which is necessary for melanin formation (see Chapter 17). Copper deficiency thus leads to hypopigmentation and in extreme cases, grey color of hair. The period of copper deficiency may be marked on hair as alternate white patches; sometimes called flag type of hair growth.

vii. Low levels can cause brain dysfunction, especially of the cerebellum, leading to ataxia.

Copper Toxicity
Excess copper intake may lead to toxic manifestations. Copper can oxidize proteins and lipids; it can enhance production of free radicals. Chronic toxicity is manifested as diarrhea and blue-green discoloration of saliva. Copper poisoning may result in hemolysis, hemoglobinuria, proteinuria and renal failure. Excess intake of copper will induce the synthesis of metallothionein (MT), found in liver, kidney and intestine. MT has a high content of cysteine and binds copper, zinc, cadmium and mercury. MT binds these metals, so as to make them nontoxic. Serum copper levels should be limited within the normal range. Low levels can cause brain dysfunction (esp. of the cerebellum, leading to ataxia) and high levels have been associated with diseases like Alzheimer's disease.

Acrodermatitis enteropathica
It is a recessive condition where zinc absorption is defective and is characterized by acrodermatitis (inflammation around mouth, nose, fingers, etc.), diarrhea, alopecia (loss of hair in discrete areas), ophthalmoplegia and hypogonadism.

Requirement of zinc
For adults is 10 mg/day; children 10 mg/day; in pregnancy and lactation 15-20 mg/day. Since iron inhibits absorption of zinc, when iron is supplemented, zinc is also given to prevent any deficiency.

Zinc toxicity
Toxic manifestations are seen when intake is more than 1000 mg/day. Toxicity of zinc is usually seen in welders due to inhalation of zinc oxide fumes. Many rat poisons contain zinc compounds, which lead to accidental poisoning.

Chronic toxicity may produce gastric ulcer, pancreatitis, anemia, nausea, vomiting and pulmonary fibrosis. Acute toxicity is manifested as fever, excessive salivation, headache and anemia.

Iodine
Three major micronutrient deficiencies seen in India are those of iodine, iron and vitamin A. In India, 235 districts are endemic for iodine deficiency. Iodine level in blood is 5-10 microgram/dl. Daily requirement is 150-200 microgram. Iodine metabolism is described in Chapter 47, under thyroid hormones.

Zinc (Zn)
Total zinc content of body is about 2 gm, out of which 60% is in skeletal muscles and 30% in bones. Highest concentration of zinc is seen in hippocampus area of brain and prostatic secretion. Rich dietary sources are grains, beans, nuts, cheese, meat and shellfish. Copper, calcium, cadmium, iron and phytate will interfere with the absorption of zinc. Zinc and copper will competitively inhibit each other’s absorption. So zinc is therapeutically useful to reduce copper absorption in Wilson's disease.

In liver, zinc is stored in combination with a specific protein, metallothionein. Zinc is excreted through pancreatic juice and to a lesser extent through sweat.

More than 300 enzymes are zinc-dependent. Some important ones are carboxypeptidase, carbonic anhydrase, alkaline phosphatase, lactate dehydrogenase, alcohol dehydrogenase and glutamate dehydrogenase. RNA polymerase contains zinc and so it is required for protein biosynthesis. Extracellular superoxide dismutase is zinc dependent and so, zinc has antioxidant activity.

Insulin when stored in the beta cells of pancreas contains zinc, which stabilizes the hormone molecule. But the insulin released into the blood does not contain zinc. The commercially available preparation, protamin-zinc-insulinate (PZI) also contains zinc. Zinc containing protein, Gusten, in saliva is important for taste sensation.

Zinc deficiency manifestations
Poor wound healing, lesions of skin, impaired spermatogenesis, hyperkeratosis, dermatitis and alopecia are deficiency manifestations of zinc. There is reduction in number of T and B lymphocytes. Macrophage function is retarded. Zinc deficiency leads to depression, dementia and other psychiatric disorders. Zinc binds with amyloid to form a plaque in Alzheimer's disease.

Fluoride
Fluoride is known to prevent caries. Caries is a Latin term, meaning "decay". In the pits and fissures of premolar and molar teeth, bacterial fermentation of residual food leads to acid production. The acid removes enamel and dentine to
expose the pulp, leading to inflammation and toothache. Topical application of fluoride will result in a fluoroapatite layer on the enamel, which protects enamel from the decay by acid.

The safe limit of fluoride is about 1 ppm in water (ppm = parts per million; 1 ppm = 1 gram of fluoride in million gram of water; this is equal to 1 mg per 1000 ml).

Fluoride ions enter the hydration shell surrounding the apatite crystals and may become incorporated into the crystal surface. The fluoroapatite makes the tooth surface more resistant to plaque bacterial attack.

**Fluorosis is More Dangerous Than Caries**
Fluoride level more than 2 ppm will cause chronic intestinal upset, gastroenteritis, loss of appetite and weight loss. Level more than 5 ppm causes mottling of enamel, stratification and discoloration of teeth.

A level more than 20 ppm is toxic, leading to alternate areas of osteoporosis and osteosclerosis, with brittle bones. This is called fluorosis. Genu valgum is the characteristic feature. Ingested fluoride accumulates in bones. It is a cumulative toxin. In fluorosis, blood concentration of fluoride increases to 50 microgram/100 ml; whereas normal value is 4 microgram/100 ml. Due to increased breakdown of bone matrix, excretion of hydroxy proline in urine is enhanced.

Nellore, Nalgonda and Prakasam districts of Andhra Pradesh and Patiala district of Punjab are badly affected. 25 million people in India are suffering from fluorosis, spread in 15 states of India. In the vicinity of irrigation dams, the water level in wells will come up, along with salts including fluoride. This has resulted in widespread fluorosis in Punjab, Rajasthan, UP, Delhi, Andhra Pradesh, Karnataka and Tamilnadu. Certain salts used in paan supari also have large content of fluoride. Fluoride-rich sources are sea fish, cheese, tea and jowar. Fluorosis is highly prevalent in areas where jowar is the staple diet. Fluorinated toothpaste contains 3,000 ppm of fluoride. Even ordinary toothpaste contains fluoride about 700 ppm.

Prevention of fluorosis is to provide fluoride free water, restriction of intake of jowar, supplementation of vitamin C and regulation of fluoride containing toothpaste.

**SELENIUM (Se)**
Selenium intake depends on the nature of the soil in which food crops are grown.

**Requirement** is 50-100 microgram/day. Normal serum level is 50-100 microgram/dl.

In mammals, glutathione peroxidase (GP) is the important selenium containing enzyme. RBC contains good quantity of glutathione peroxidase.

Thyroxin is converted to T3 by 5’-de-iodinase, which is a selenium containing enzyme. In Se deficiency, this enzyme becomes less active, leading to hypothyroidism.

Selenium concentration in testis is the highest in adult tissue. It is necessary for normal development of spermatozoa. It is concentrated in the mid-piece of spermatozoa as a specific seleno-protein in mitochondria.

The UGA codon (see Chapter 41) is acting as the codon for direct insertion of seleno-cysteine into selenium containing enzymes. Seleno-cysteine is directly incorporated into the protein during biosynthesis. So, seleno-cysteine may be considered as the 21st amino acid (see Box 3.2).

Selenium acts as a nonspecific intracellular anti-oxidant. This action of Se is complementary to vitamin E. Availability of vitamin E reduces the selenium requirement. In Se deficiency, tissue vitamin E content is depleted.

In Keshan province in China, the soil is deficient in selenium. This leads to prevalence of Keshan disease. It is characterized by multifocal myocardial necrosis, cardiac arrhythmias and cardiac enlargement. Selenium is known to cure the disease. Isolated selenium deficiency in other parts of the world caused liver necrosis, cirrhosis, cardiomyopathy and muscular dystrophy.

Selenium toxicity is called selenosis. Selenium is present in metal polishes and anti-rust compounds. The toxicity symptoms include hair loss, falling of nails, diarrhea, weight loss, and garlicky odor in breath. The last mentioned symptom is due to the presence of dimethyl selenide in expired air. Kaschinbeek disease is characterized by degenerative osteoarthritis.

**MANGANESE (Mn)**
Total body manganese is 15 mg. Maximum concentration is in liver (1.5 ppm). In the cells, it is mainly seen inside the nuclei, as complexed with nucleic acids.

**Requirement** of manganese is 5 mg/day.

**Sources:** Nuts are good sources and tea leaves are exceptionally rich in manganese. Only about 3% of ingested manganese is absorbed.

**Metabolism:** The absorption is inhibited by iron. In blood, manganese is bound to the specific carrier protein, transmanganin, a beta globulin. Manganese is excreted through bile.

**Functions:** The following enzymes either contain or are activated by manganese: Hexokinase, phosphoglucomutase, pyruvate carboxylase, isocitrate dehydrogenase, succinate dehydrogenase, arginase, glutamine synthetase and Mn-dependent superoxide dismutase. Manganese is an integral part of glycosyl transferases, responsible for synthesis of glycoproteins and chondroitin sulfate. Mn is also required for RNA polymerase activity.

**Deficiency** leads to impaired growth and skeletal deformities. Chondroitin sulfate generation is impaired so that organic matrix of bone and cartilage becomes abnormal.

**MOLYBDENUM (Mo)**
Mean dietary intake of molybdenum is 100 microgram/day. Most of the absorbed molybdenum is excreted through urine. Higher protein and cysteine intake will cause higher excretion of molybdenum. It is present in cereals. Liver contains maximum content of Mo in the body.

**Metabolism:** The absorption is inhibited by iron. In blood, manganese is bound to the specific carrier protein, transmanganin, a beta globulin. Manganese is excreted through bile.

**Functions:** Xanthine oxidase and aldehyde oxidase contain molybdenum, a substituted pterin to which molybdenum is bound by two sulfur atoms. Mo deficiency causes depression of xanthine oxidase activity, increased excretion of xanthine and decreased uric acid excretion.

Excess intake leads to molybdenosis. It is characterized by growth retardation anemia and diarrhea. Copper and cysteine are effective in removing Mo from the body and in
Chapter 35; Mineral Metabolism and Abnormalities  431

reducing toxicity. Higher levels of Mo in food will impair the absorption of copper.

Deficiency of Mo is associated with increased incidence of esophageal cancer.

COBALT (Co)
Vitamin B\textsubscript{12} is the only important nutrient for human beings that contain cobalt (see Chapter 34). Cobalt content of vitamin B\textsubscript{12} is about 4% by weight. Cobalt stimulates the production of erythropoietin and continued use in animals has resulted in polycythemia.

NICKEL (Ni)
Normal plasma level of nickel is 0.5 microgram /dl. Nickel content of hair in female is 4 ppm, while in male it is 1 ppm. Nickel containing enzymes are urease and methylcoenzyme reductase. Nickel inhibits acid phosphatase. Nickel is necessary in the production of pigments in fish, birds and insects. Some chocolate preparations may contain nickel levels more than permitted. Nickel in higher concentrations may be carcinogenic. Deficiency may lead to decreased utilization of iron. Requirement is 500 microgram/day.

CHROMIUM (Cr)
Trivalent and hexavalent atoms of chromium are biologically active. Total body content of chromium is 6 mg, and this decreases with age. Cooking in stainless steel containers increases the Cr content of food. Daily requirement is 30 microgram. Blood level of chromium is 25 nanogram/dl. Affinity of chromium for transferrin is the same as that of iron, and the two ions compete for binding to the protein.

In chromium deficiency, glucose tolerance is impaired. The efficiency of binding of insulin to its receptors on the peripheral cells is improved by chromium. Deficiency also leads to impaired growth, decrease in fertility and sperm count.

Radioactive (\textsuperscript{57}Cr) is widely used to tag RBC. These tagged RBCs when injected back to the patient will be seen in circulation and the rate of hemolysis could be calculated. \textsuperscript{57}Cr-labelled target cells are used to demonstrate the cytolytic effect of T lymphocytes and NK cells.

Chromium toxicity is an occupational hazard in workers of tanning industry. Liver and kidney damage are seen. Upper safe limit of chromium is 200 microgram per day. Chromium in higher concentrations may be carcinogenic. Tobacco is rich in chromium, and this is implied partly in the carcinogenic effect of tobacco.

LITHIUM (Li)
It has the atomic number 3. It is the lightest alkali metal. Lithium is an essential growth factor in tissue culture. Normal human skeletal muscles contain 2-200 nanogram/g of wet weight. Higher concentrations are seen in brain. Mean intake is 50 microgram/day.

Lithium is used in treating manic depressive psychosis (bipolar disorders), the dose being 25-500 mg/day. Lithium will counteract both mania and depression. Therapeutically optimum concentration of Li in plasma is 7-10 microgram/ml, while 12 microgram is toxic. Since margin of safety is narrow, the treatment requires constant monitoring of blood level. Li causes inhibition of inositol phosphatase, leading to increased concentration of inositol phosphate in brain. Li elevates serotonin levels and reduces catecholamines in brain tissue. Lithium toxicity leads to hypothyroidism, hyperparathyroidism and kidney damage.

Related topics
Sodium, Potassium and Chloride are very important electrolytes, having much clinical applications. These are described in Chapter 30. A summary of the mineral metabolism is shown in Table 35.4. Lead, Cadmium, Phosphorus and Mercury are toxic minerals; these are described in Chapter 38. Iodine metabolism is described in Chapter 47.
CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Calorific value, respiratory quotient
2. Basal metabolic rate (BMR)
3. Specific dynamic action (SDA)
4. Proximate principles
5. Nitrogen balance
6. Nutritional values of proteins
7. Limiting amino acids, supplementation
8. Kwashiorkor and marasmus
9. Prescription of the diet
10. Glycemic index

A sound knowledge of the principles of nutrition is of paramount importance in developing countries, where more than 60% populations are below the poverty line. Dietetics is the science of food and nutrients, their action, interaction and balance in health and disease. The main purpose of the food is to provide energy for muscular activity and also to supply basic body building materials such as essential amino acids.

Calorific Value
The energy content of food materials is measured in calories. One calorie is the heat required to raise the temperature of 1 g of water through 1°C. Since it is a very small unit, in medical practice, the energy content is usually expressed in kilocalorie (kcal) which is equal to 1000 calories. [One kilo calorie is equal to 4.2 kilojoules (kJ)]. The maximum available energy contained in a food can be measured by burning it in an atmosphere of oxygen in a bomb calorimeter.

The calorific value of nutrients otherwise known as "energy density" (energy yield per unit weight of food) is given in Table 36.1.

Respiratory Quotient (RQ)
i. Respiratory quotient is defined as the ratio of volume of CO₂ produced in L/g to the oxygen consumed in L/g.
ii. RQ of carbohydrates is 1; RQ of fats is 0.7; that of proteins is 0.8 (Table 36.1).
iii. For a mixed diet it is between 0.7 and 1, often around 0.82-0.85. When the rate of utilization of fat increases in relation to carbohydrates, RQ falls. This happens in diabetes mellitus, when utilization of carbohydrate is reduced. The RQ is lowest when ketolysis is very active.
iv. The energy produced is approximately equal to 20 kJ/L of oxygen for all metabolic fuels (Table 36.1, last column).

Energy Requirements of a Normal Person
While calculating the energy requirements, we have to consider the energy required for:
i. Maintenance of basal metabolic rate (BMR)
ii. Specific dynamic action or thermogenic effect of food
iii. Extra energy expenditure for physical activities.

Basal Metabolic Rate

1. Definition

i. The basal metabolic rate (BMR) is the energy required by an awake individual during physical, emotional and digestive rest. It is the minimum amount of energy required to maintain life or sustain vital functions like the working of the heart, circulation, brain function, respiration, etc. The metabolic rate during sleep is less than BMR.

ii. Resting metabolic rate (RMR) is the measure of energy required to maintain life or vital functions. The subject is awake and non-fasting. It is approximately about 3% higher than the BMR.

iii. BMR is measured directly by the heat evolved, or indirectly by the volume of oxygen consumed and carbon dioxide evolved per unit time.

2. Measurement of BMR

i. Procedure: Atawater-Benedict-Roth basal metabolism apparatus (closed circuit method) is used. The person should be awake, but at physical and mental rest. The temperature of surroundings should be comfortable (about 25°C). The subject breathes in oxygen from a metal cylinder. The CO₂ produced is absorbed in soda lime. The subject is asked to breathe through a mouthpiece for 6 minutes. The oxygen present in the cylinder is utilized during this time. The volume of oxygen consumed is recorded.

ii. Calculation: The BMR is calculated from oxygen consumption, calorific value and surface area. Let oxygen consumed in 6 minutes be "Y" liters. It is shown that calorific value of oxygen is 4.8, that is, when 1 liter of oxygen is utilized, 4.8 kilocalories are generated. Therefore, heat produced in 6 minutes = 4.8 × Y or heat produced in 24 hours = 4.8Y × 10 × 24 kilocalories.

iii. Indirect calorimetry: When deuterium (²H) and ¹⁸O labelled water is given, these isotopes are eliminated at different rates. Deuterium is eliminated only as water, while oxygen is eliminated as CO₂ as well as water. The difference between the two elimination rates is, therefore, a measure of CO₂ production. The double labelled water method (Nathan Lifson) provides a measure of total CO₂ production over 2-3 weeks. The method is useful to measure alterations in energy requirements during growth, pregnancy, lactation, etc.

3. Factors Affecting BMR

i. Age: During the period of active growth, BMR is high. It reaches a maximum by 5 years of age. In old age BMR is lowered.

ii. Sex: Males have a higher BMR than females.

iii. Temperature: BMR increases in cold climate as a compensatory mechanism to maintain body temperature. Eskimos have a higher BMR.

iv. Exercise: The increase in BMR during exercise is due to increased cardiac output. Starvation lowers BMR.

v. Fever: 12% increase in BMR is noticed per degree centigrade rise in temperature.

vi. Thyroid hormones: Since thyroid hormones have a general stimulant effect on rate of metabolism and heat production, BMR is raised in hyperthyroidism and lowered in hypothyroidism. All other factors (No. 1 to 6) are taken into account in the definition of BMR. Thus, thyroid function determines the changes in BMR.

4. Normal Value for BMR

i. Since BMR is affected by body surface area, it is usually expressed in kilocalories per hour/square meter of body surface. Body surface area is calculated using the formula (Eugene DuBois and Delafield DuBois, 1915). A = W ⁰.⁴²⁵ × H ⁰.⁷²⁵ × 71.84, where A = area in sq cm, H = height in centimeters and W = weight in kilograms. Nomograms showing body surface area from height and weight are also available. The BMR is then calculated from the values of oxygen consumption, calorific value and surface area. Nomograms showing body surface area from height and weight are also available.

ii. For adult men normal value for BMR is 34-37 kcal/square meter/hour, and for women, 30-35 kcal/Sq.m./hour. For easier calculations, BMR for an adult is fixed as 24 kcal/kg body weight/day. The values thus obtained are rounded to the nearest whole number.

Specific Dynamic Action (SDA)

i. This refers to the increased heat production or increased metabolic rate following the intake of food (thermogenic effect of food) (diet-induced thermogenesis).

ii. Part of this is due to the expenditure of energy for digestion; absorption and active transport of products of the digestion. Another reason for this expenditure of energy is that reserve materials such as glycogen, triacyl glycerol, protein, etc. are synthesized from small molecules available after digestion.

iii. This energy is trapped from previously available energy, so that the actual energy from the food is lesser than that of theoretical calculation. SDA can be considered as the activation energy needed for a chemical reaction. This activation energy is to be supplied initially.
iv. Suppose a person takes 250 g of carbohydrates; this should produce 250 \times 4 = 1000 kcal. But before this energy is trapped, about 10% energy (=100 kcal) is drawn from the reserves of the body. Thus the net generation of energy is only 1000 minus 100 = 900 kcal.

v. If the person wants to get 1000 kcal, he should take food worth 1100 kcal. Thus additional calories, equivalent to SDA have to be added in diet.

vi. The values of SDA are: for proteins 30%, for lipids 15%, and for carbohydrates, 5%. This means that out of every 100 grams of proteins consumed, the energy available for doing useful work is 30% less than the calculated value.

vii. Hence for a mixed diet, an extra 10% calories should be provided to account for the loss of energy as SDA.

viii. It is a common experience that during hot weather following the consumption of a protein rich meal, one feels hot and humid for a while.

Physical Activity

i. The energy requirements would depend on the occupation, physical activity and lifestyle of the individual.

ii. The activity level may be divided into 3 groups—sedentary, moderate and heavy. Additional calories are to be added for each category:

iii. For sedentary work, +30% of BMR; for moderate work, +40% of BMR; and for heavy work, +50% of BMR should be added (see Tables 36.2 and 36.3).

iv. Requirement for energy during pregnancy is +300 kcal/day, and during lactation is + 500 kcal/day, in addition to the basic requirements.

v. The energy requirement of a 55 kg male doing moderate work, may be calculated as shown in Table 36.4.

Requirements of Dietary Nutrients

The recommended dietary allowance (RDA) provides extra provisions to prevent the development of deficiencies.
of deficiency. The RDA has been prescribed for all the essential nutrients as per the stipulations of the WHO and FAO. The Indian Council of Medical Research (ICMR) has suitably modified these for Indian conditions (see also Appendix V).

Proximate principles
In the diet proximate principles are carbohydrates, fats and proteins. Moreover, required amounts of minerals and vitamins are also to be provided. Further, additional requirements for growth, pregnancy, lactation and convalescence are to be provided in the food.

**IMPORTANCE OF CARBOHYDRATES**
The dietary carbohydrates provide a major fraction of the body’s energy needs. Ideally carbohydrates may provide about 60-65% of total calories. In addition to calories, the carbohydrates also provide dietary fiber.

1. Dietary Carbohydrates
   i. **Available carbohydrates**: These can be metabolized by the body to give energy, e.g. starch and sugars (see Table 36.5).

<table>
<thead>
<tr>

<td>Absorbs water, slows gastric emptying, binds bile acids, increases their excretion.</td>
</tr>
</tbody>
</table>

   ii. **Unavailable carbohydrates**: These cannot be assimilated and constitute only the dietary fiber (see Table 36.7).

   iii. The major dietary polysaccharide is **starch**. It is digested by amylase to maltose and then hydrolyzed to glucose. This glucose is the major source of fuel for most organs and tissues. Excess is converted to fat and stored.

   iv. On cooking starch is made more soluble and accessible to digestive enzymes. Cereals, pulses and tubers are the major sources of starch in the diet. Germination of legumes leads to partial breaking down of the starch present in them. Table 36.6 gives a list of common food items with their starch content.

2. Sucrose
   i. Cane sugar is mainly used as a sweetening agent. In young children high intake of sucrose and sucrose-rich food items predispose to the development of dental caries. Sucrose is easily fermented by the bacteria present in dental plaque, which would damage the enamel and lead to caries (tooth decay).

   ii. In adults, consumption of large quantities of refined sugars is not advisable since they tend to produce a sudden rise in blood glucose levels. This will also lead to excessive calorie intake.

   iii. Sucrose consumption also results in increased levels of plasma lipids.

   iv. While prescribing diets for diabetic patients and for weight reduction, sucrose should be strictly avoided. Jaggery, an alternative source of sucrose is beneficial, since it is a good source of iron.

3. Dietary Fiber
   i. The unavailable or **indigestible** carbohydrate in the diet is called dietary fiber.

   ii. Dietary fiber is necessary to maintain the normal motility of gastrointestinal tract. The comparatively high incidence of colon cancers in developed countries, and the low incidence of the same in vegetarian population like Indians, pointed to the importance of dietary fiber. Table 36.7 gives a list of unavailable carbohydrates, their chemical nature and possible physiological effects.
iii. Diet rich in fiber improves bowel motility, prevents constipation, decreases reabsorption of bile acids thus lowering cholesterol level and improves glucose tolerance. For **hypoglycemic** and **hypolipidemic** effect, see glycemic index at the end of this Chapter. The beneficial effect is more with soluble fiber present in vegetables and only a diet having plenty of vegetables and green leaves will have the desired effect.

iv. Fiber requirement is about 30 g/day. The inclusion of fiber rich food in weight reducing diets is found to be helpful, since it provides a feeling of fullness without consumption of excess calories.

**NUTRITIONAL IMPORTANCE OF LIPIDS**

1. **Neutral Fats or Triacyl Glycerols**

i. Fats provide a concentrated source of energy. In developed countries, the percentage of calories derived from fats may be as high as 40%, but in the developing countries it is much less, around 10%.

ii. A minimum intake of lipids is essential since the requirements of fat soluble vitamins and essential fatty acids are to be met.

</tr>
</tbody>
</table>

iii. Fats increase the taste and palatability of food. They are the favored cooking medium.

iv. **Visible fat** or fat consumed as such, e.g. butter, ghee, oils. Recommended daily intake of visible fat is 10% of calories or 20 g/day; in pregnancy 30 g/day and during lactation 45 g/day.

v. **Invisible fat** or fat present as part of other food items, e.g. egg, fish, meat, cereals, nuts and oil seeds. Even cereals contain 1 g of fat per 100 g. More than half of essential fatty acid in Indian diet is in the form of invisible fat.

2. **Cholesterol and Heart Diseases**

i. The atherogenic effect of cholesterol and the risk of coronary artery disease in people with hypercholesterolemia are described in Chapter 25. Hence it is always advisable that dietary intake should be restricted.

ii. Food items known to be rich in cholesterol (egg yolk, liver, brain, kidney) are to be consumed in limited amounts. Table 36.8 gives a list of food items with their cholesterol content.

iii. Vegetables, cereals and pulses do not contain any cholesterol. On the other hand, vegetable sterols will inhibit cholesterol absorption.

iv. Saturated fats raise serum cholesterol; while unsaturated fats lower it. Therefore, unsaturated fat (vegetable oils and fish oils) are to be preferred.

v. The poly unsaturated fatty acids (PUFA) are present in vegetable oils and fish oils (Table 36.9). They are **essential fatty acids** and precursors of prostaglandins and leukotrienes. PUFAs are required for esterification and excretion of cholesterol. They reduce the cholesterol level in blood and are **anti-atherogenic** (see Chapter 25).

vi. The omega-3 fatty acids from fish oils decrease the plasma lipoproteins, (VLDL and LDL) and thereby decrease the risk of coronary artery disease. The contents of PUFA in oils are given in Table 36.10; a detailed list is given in Table 7.4.

vii. High fiber content also reduces serum cholesterol, lowers LDL fraction and raises HDL fraction. Whole cereals, pulses, leafy vegetables and fruits contain good quantity of fiber.
Moreover, the fat content should be such that saturated fatty acid (SFA) : mono unsaturated fatty acid (MUFA) : poly unsaturated fatty acid (PUFA) may be in 1:1:1 ratio.

Further, cholesterol intake should be less than 250 mg/day.

### IMPORTANCE OF PROTEINS

#### 1. Essential Amino Acids

i. Proteins form the building blocks for body tissues. Only 10-15% of the total energy is derived from proteins. When enough carbohydrates are present in the diet, the amino acids are not used for yielding energy. This is known as the protein sparing effect of carbohydrates. During starvation, amino acids may act as energy sources.

ii. Proteins are the only source of essential amino acids (see Box 3.1). The requirement of protein is shown in Table 36.11. As per the WHO/FAO recommendation in 1985, the safe levels of protein intake for an adult is 0.75-0.8 g/kg/day.

iii. For the synthesis of body proteins, all the essential amino acids should be supplied in adequate quantities at the same time.

iv. Cysteine and tyrosine can be synthesized, when methionine and phenyl alanine are available; thus requirement of the precursor amino acid is determined by the availability of the product. The remaining amino acids can be synthesized, provided there is enough supply of proteins in total. Only 3 amino acids (alanine, aspartate and glutamate) are truly dispensable, as they can be synthesized from pyruvate, oxaloacetate and alpha ketoglutarate respectively; and these precursors are generally available in plenty.

#### 2. Nitrogen Balance

i. A normal healthy adult is said to be in nitrogen balance (Fig.36.1), because the dietary intake (I) equals the daily loss through urine (U) feces (F) and skin (S).

\[ I = U + F + S \]

ii. When the excretion exceeds intake, it is negative nitrogen balance.

iii. When the intake exceeds excretion, it is a state of positive nitrogen balance.

iv. Nitrogen balance can be actually measured by calculating the dietary intake of protein nitrogen (16% of the weight of protein) and measuring the daily excretion.
3. Factors Affecting Nitrogen Balance

i. **Growth:** During the period of active growth, a state of positive nitrogen balance exists. On an average when a person gains 5 kg, about 1 kg proteins are added to the body. For this, about 160 g of nitrogen has to be retained, so he/she has to be in positive nitrogen balance.

ii. **Hormones:** Growth hormone, insulin and androgens promote positive nitrogen balance, while corticosteroids cause a negative nitrogen balance.

iii. **Pregnancy:** A pregnant woman will be in a state of positive nitrogen balance due to the growth of fetus.

iv. **Convalescence:** A person convalescing after an illness or surgery will be in positive nitrogen balance, due to active regeneration of tissues.

v. **Acute illness:** Negative nitrogen balance is seen in subjects immediately after surgery, trauma and burns.

vi. **Chronic illness:** Malignancy, uncontrolled diabetes mellitus and other debilitating diseases show negative nitrogen balance. For explanation, see Cachexia, on the next page.

vii. **Protein deficiency:** The deficiency of even a single essential amino acid can cause negative nitrogen balance. Prolonged starvation is another important cause.

4. Maintenance of Nitrogen Balance

To maintain the nitrogen balance, one has to satisfy the need for nitrogen intake, which are:

i. Obligatory nitrogen loss is 3.5 g of N/day for a 65 kg person (urinary, fecal and cutaneous loss). This could be equivalent to 22 g of protein.

ii. Requirement for protein turnover. The minimum daily requirements to compensate for the above two categories are 0.75-0.8 g/kg wt of good quality protein.

iii. Protein requirements for growth. This is applicable in the case of infants, children, adolescents, pregnancy, lactation and convalescence. As growth stops, protein requirement also decreases.

5. Nutritional Values (Nutritional Indices)

5-A. Assessment of Nutritional Values

Whipple (Nobel Prize, 1934) introduced plasmapheresis as a means to assess the nutritional value of proteins. Plasma from animal was taken, albumin was removed, the rest of plasma was introduced back into the animal. The time for regeneration of original level of albumin in plasma was taken as a parameter of the quality of the food given to the animal.

The modern, easier way, to assess the nutritional value of a protein, is to give that protein as the only source of nitrogen to an animal, and assess the weight gain (Fig. 36.2). The protein content of various food items are shown in Appendix IV. The nutritive value is shown in Table 36.12. The following indices are used to assess the nutritional value of proteins.

5-B. Biological Value (BV) of Protein

It is the ratio between the amount of nitrogen retained and nitrogen absorbed during a specific interval.

\[
BV = \frac{\text{Retained nitrogen} \times 100}{\text{Absorbed nitrogen}}
\]

Suppose 127 mg of a particular protein was consumed by a rat in a day and 4 mg is recovered in feces and 24 mg is seen in urine. Then

Amount ingested = 127 mg
Amount absorbed = 127 – 4 = 123 mg
Amount retained = 123 – 24 = 99 mg
Therefore BV = 99/123 × 100 = 81%

5-C. Net Protein Utilization (NPU)

NPU = retained nitrogen/intake of nitrogen × 100

In the above example,

NPU of protein "A" = 99/127 × 100 = 78%

and for protein "B", it is 4.5/100 × 100 = 4.5%.

Thus NPU is a better index than BV to denote nutritional quality and availability of a protein (Table 36.12).

5-D. Net Dietary Protein Value (NDPV)

This will assess both quantity and quality of the proteins in the diet.

\[
\text{NDPV} = \text{Intake of N} \times 6.25 \times \text{NPU}
\]

5-E. Protein Efficiency Ratio or PER

It is the weight gain per gram of protein taken. The essential amino acid content can also be expressed in terms of chemical score (mg of amino acid per gram of protein). By comparing the chemical score of different proteins with egg protein which is taken as a reference protein, the essential amino acid content can be assessed.

6. Limiting Amino Acids

Certain proteins are deficient in one or more essential amino acids. If this particular protein is
fed to a young rat as the only source of protein, it fails to grow. This amino acid is said to be the **limiting amino acid**. Limiting amino acid is that which limits the weight gain when a protein is supplied to an animal (Fig. 36.2).

**7. Mutual Supplementation**

This problem may be overcome by taking a mixture of proteins in the diet. **Mutual supplementation of proteins** is thus achieved (Table 36.13). For example, pulses are deficient in methionine, but rich in lysine.

On the other hand, cereals are deficient in lysine, but rich in methionine.

Therefore, a combination of pulses plus cereal (e.g. chappathi + dal) will cancel each other’s deficiency and become equivalent to first class protein. The supplementation effect of proteins may be seen in weight gain in animals (Fig. 36.3).

**PROTEIN–ENERGY MALNUTRITION**

i. It is the most widespread nutritional problem in developing countries; predominantly affecting children. The prevalence rate varies from 20-50% in different areas depending on socioeconomic status and level of education and awareness.

ii. At one end of the spectrum of malnutrition is **marasmus** (Greek word, "to waste"), which results from a continued severe deficiency of both dietary energy and proteins (primary calorie inadequacy and secondary protein deficiency).

iii. At the other end of the spectrum is **kwashiorkor**, where isolated deficiency of proteins along with adequate calorie intake is seen. Kwashiorkor means "sickness the older child gets, when the next child is born", a term from the local language of Ga tribe of Ghana. A classification by WHO is based on body weight as a percentage of standard body weight (Table 36.14).

**Biochemical Alterations in PEM**

Table 36.15 gives a comparison between kwashiorkor and marasmus.

</tbody>
</table>

i. The **hallmarks** of kwashiorkor are hypoalbuminemia, poor wound healing and edema.

ii. **Hypoalbuminemia**: Albumin values less than 2 g/dl is a biochemical marker in cases of kwashiorkor. In marasmus, this may not be so low.

iii. IgG increases due to associated infections.

iv. **Fatty liver** is seen in some cases of kwashiorkor, but not in marasmus. Fatty liver is due to decreased lipoprotein synthesis.

v. Glucose tolerance is often normal, but **hypoglycemia** may be seen in marasmic children.

vi. **Hypokalemia** and dehydration may be seen when there is diarrhea.

vii. **Hypomagnesemia** is a usual finding.

**Treatment of Protein Energy Malnutrition**

Optimal response is observed with diets providing 150-200 kcal/kg body weight and 3-4 g of protein/kg body weight. A mixture of three parts of vegetable proteins (Bengal gram or peanuts) and one part of milk protein is found to be very effective. It is monitored by disappearance of edema, rise in serum albumin level and gain in weight.

**Sequelae of Protein Calorie Malnutrition**

Severe malnutrition in early life can lead to permanent and irreversible physical and functional deficits. Severe persistent malnutrition may have deleterious effects on the intellectual capacity in later life. There may not be any sequelae where the moderate and mild forms are corrected in time. Since the children of today are the force of tomorrow, a nationwide effort is to be made to eradicate childhood malnutrition.

**Cachexia due to Diseases**

Patients with advanced cancer, AIDS (HIV infection), tuberculosis, etc. are seen as undernourished; this is called cachexia. This is similar to marasmus, but the loss of body protein is more than that seen in simple malnutrition. Cachexia is explained by the following facts:

1. Chronic infections and cancer will induce production of inflammatory **cytokines**; this leads to breakdown of protein by ubiquitin or proteasome pathway. This increases the energy expenditure. BMR is considerably increased.

2. Cytokines also stimulate **uncouplers** such as thermogenin, leading to increased oxidation and thermogenesis without trapping energy.

3. **Futile cycling of lipids** occurs, as the hormone sensitive lipase is activated by proteoglycans secreted by tumors.

So, free fatty acids are liberated from adipose tissue. These are utilized for triacyl glycerol synthesis in liver; this is a process that needs high expenditure of energy. This fat is again reaching adipose tissue through VLDL, thus completing the futile cycle.

4. Most of the tumors preferentially use **anaerobic glycolysis**, the end result being lactic acid. This lactate enters the gluconeogenesis pathway in liver, which is an energy consuming reaction (requiring 6 ATPs for each glucose unit).
OBESITY
Malnutrition may be of two types; undernutrition or overnutrition. The latter is otherwise called obesity. Obesity is the most prevalent nutritional disorder in prosperous developed countries. In India, obesity is prevalent in affluent people. This is because human race is accustomed to poverty and malnutrition from time immemorial, and the body is designed to store energy whenever available. This is the first generation in history, where foodstuffs are in plenty. So, by habit people eat more and get obese. Obesity is the condition in which excess fat has accumulated. This is due to the increased energy intake and decreased energy expenditure. The obesity index is calculated as W/H² (where W = weight in kg and H = height in meters); it is used to assess the obesity. "Obesity index" is an old terminology; the modern expression is Body Mass Index (BMI). A person is obese when BMI exceeds 27.8 kg/m² in men and 27.3 kg/m² in women (excess of 120% of desirable body weight).

Obesity can occur only as a result of ingestion of food in excess of the body's needs. The major causes are food habits (intake of calorie rich food in excess amounts) and lack of exercise. There is an increase in the number (hyperplasia) and size (hypertrophy) of the adipocytes. Genetic predisposition has been suggested. If one parent is obese, there are 50% chances for the children becoming obese. However, no gene alone is responsible for the production of obesity.

Diseases related to Obesity
Sensitivity of peripheral tissues to insulin is decreased. The number of insulin receptors are decreased in adipose tissue cells. Plasma insulin levels may be elevated. Obesity is associated with substantially increased cardiovascular risk. Increased waist to hip ratio (abdominal obesity) is a greater risk. In metabolic syndrome (Syndrome-X) insulin resistance, hyperglycemia, hyperlipidemia (increased LDL and decreased HDL) and obesity are seen.

The major ill effects of obesity are increased risk of coronary artery disease, diabetes mellitus, hypertension, metabolic syndrome and a reduced lifespan. Calorie-fat-restricted diet may retard ageing process and extend the lifespan.

Treatment of Obesity
Lifestyle modification is the best suitable technique. The goal is to reduce the intake of calories and fat. Frequent small meals with lots of vegetables will make the food palatable and give a feeling of satiety. Controlled exercise is very useful. See Box 36.1 for the special diet for obesity. In patients with higher grades of obesity, drugs may be given to decrease appetite (endocannabinoid receptor antagonists will decrease the intake of food).

Regulators of Appetite
Hypothalamus has the central control of appetite. Psychologic, genetic, neural and humoral factors are involved in the control. High level of cortisol (as in Cushing syndrome) leads to obesity. MSH (melanocyte stimulating hormone) is a powerful appetite suppressant, and any genetic mutation in the gene will have its effect. Patients with Prader Willi syndrome, (deletion of a part of chromosome 15) and Laurence-Moon-Biedl syndrome (genetic defect) tend to over eat and are obese. Polypeptides that increase appetite are: Neuropeptide Y (NPY), Ghrelin, Melanin concentrating hormone (MCH), Orexin, Endocannabinoid, Cholecystokinin (CCK), Polypeptide YY (PYY), Insulin and Cortisol. Appetite decreasing factors are: Leptin, Melanocyt stimulating hormone (MSH), Glucagon related peptide 1 (GLP1), Cocaine-amphetamine related transcript (CART) and Serotonin.

Adipose Tissue Talks to Brain Through Factors
1. Leptin (Greek leptos = thin) is a hormone secreted by adipocytes. It is a 16 kDa protein with 167 amino acids. It plays a key role in regulating energy intake and energy expenditure, including appetite and metabolism. It is the product of “ob” gene (in mice). The corresponding human gene is “Lep” which is present on human chromosome 7. Fasting or following a very low calorie diet (VLCD) lowers leptin levels. Leptin administration inhibits gastric appetite (endocannabinoid receptor antagonists will

Box 36.1. Diet for Obesity (Dieting)
Different types of diets are prescribed during dieting, all of which aim at a negative calorie balance. Consuming less food or consuming a low fat diet will not have the desired effect, because the body will have a tendency to switch to the fasting metabolic profile soon after meals. Robert Atkins proposed a low carbohydrate ketogenic high protein diet (Atkin’s diet) for losing weight. According to Atkins, only 20 g of carbohydrate per day is given (normal desirable intake is 100-120 g per day), but unlimited consumption of fat and proteins are permitted. When such a diet is consumed, the liver will be predominantly glucogenic and ketogenic. Peripheral tissues will utilize the excess ketone bodies for their energy needs. The substrate for gluconeogenesis is mainly glucogenic amino acids. ATP is provided by oxidation of fatty acids. Insulin secretion as well as the increment in glucose in the post prandial state is low. This low carbohydrate diet was found to give promising results in 6-12 week trials compared to low calorie, low fat diets. More long-term trials are necessary to prove the efficacy of the low carbohydrate ketogenic diet.
ulcer formation in rats and stimulates growth of esophageal adenocarcinoma cells. It is mainly produced by white adipose tissue and to a certain extent by gastric mucosal cells. It functions as a satiety signal. It is an index of the energy reserve in the body. When the energy reserve is adequate, leptin levels are increased and this would suppress further food intake. When there is enough fat deposit, leptin secretion is stimulated. Leptin inhibits neuropeptide-Y secretion, and so when fat depots are full, appetite is decreased. Mutation of leptin or mutation of its receptor in hypothalamus leads to removal of this feedback mechanism; so uncontrolled eating and obesity are the results. Obesity is associated with leptin resistance and high levels of leptin in plasma. Ob gene produces leptin and in its absence, obesity develops. The administration of recombinant leptin is found to be effective in the control of childhood obesity.

2. Neuropeptide-Y, a hypothalamic polypeptide, stimulates desire for carbohydrates. Neuropeptide Y is also secreted by the small intestinal (ileum) N cells. It is also present in the entire nervous system, adrenal gland and pancreas. The action is to inhibit insulin secretion.

3. Ghrelin is secreted by P/D1 cells lining the fundus of the human stomach and epsilon cells of the pancreas. It is a polypeptide, in which fatty acids are incorporated. It stimulates hunger and appetite by acting on the hypothalamus. Plasma level of ghrelin is increased in fasting state, which produces hunger signals. Ghrelin levels increase before meals and decrease after meals. Ghrelin also plays a significant role in the hippocampus, and is essential for cognitive adaptation to changing environments and in the process of learning. Recently, ghrelin has been shown to activate the endothelial isoform of nitric oxide synthase.

4. Another neuropeptide, Galanin increases the craving for fatty foods. Figure 36.4 shows the factors released by adipose tissue cells.

PRESCRIPTION OF DIET
1. General Principles

Recommended dietary allowances (RDA) of nutrients are given in detail in Appendix III. While prescribing the diet of a person; the following general rules are to be remembered:

**Box 36.2. Steps in Prescribing a Diet**

This problem is approached by solving the following questions sequentially:

1. What is the requirement of the person with regard to calorie and other essential nutrients?
2. What is the quantity of proximate principles required?
3. Which composition of food will give the above requirement?
4. How can a palatable diet that contains these food items be prescribed?
5. The total quantity may be divided into 3 or 4 meals at convenient intervals of time.

i. **The ideal body weight:** The underweight person should be given more nutrients and the overweight person should reduce calorie intake. The ideal body weight for an average adult male is taken as 48 kg for a height of 153 cm, plus or minus 1.25 kg for every cm. For an average adult female, the ideal body weight is 45 kg for a height of 153 cm, plus or minus 1 kg for every cm. For exact values, see Appendix VIII.

ii. **Protein requirement:** 1 g per kg body weight for adults and 2 g per kg for children. During pregnancy and lactation, protein requirement is about 2.5 g per kg.

iii. **Calorie requirement:** This depends on age, sex, height, weight, health status and above all on the physical activity and occupation. As a rule of thumb, the calorie requirement for a person is taken as 30-35 kcal per kg of ideal body weight. For sedentary habits, lower values (30 kcal) and for moderate muscular activities, higher values (35 kcal) are prescribed.

Considering the average weight of adult Indians between 55 to 65 kg, average calorie requirement will be between 1700 and 2300 kcal per day.

An extra allowance of 300 kcal is necessary during pregnancy and lactation periods. During convalescence, extra 300 kcal has to be supplied.

iv. **Specific dynamic action:** Extra energy is to be supplied to account for SDA.

v. **Ratio:** Balanced diet should contain calories from carbohydrate, proteins and fat in the ratio of 60:20:20. The important steps in prescribing the diet are enumerated in Box 36.2.

2. **First Step: Calorie Requirement**

For a 60 kg sedentary man, the energy requirement is $60 \times 30 = 1800$ kcal plus additional allowance for

**Fig. 36.4. Adipose tissue as an endocrine organ**
specific dynamic action \((1800 \times 10\% = 180)\). Therefore, the total requirement is roughly 2000 kcal. The recommended dietary intake for a 60 kg sedentary man, based on the above principles is given in Table 36.16.

3. Second Step: Proximate Principles
He requires 60 g proteins. This will give \(60 \times 4 = 240\) kcal of energy. His total requirement is 2000 kcal. Therefore, carbohydrates plus fats should produce \((2000 – 240) = 1760\) kcal. As a general rule, about 20% of total calories are supplied by fat. Therefore, fats should supply \(1760 \times 20\% = 350\) kcal which is provided by \((350/9) = 35\) g of fats. (About 30% of the total fat may be supplied as poly unsaturated fatty acids).

The rest 1400 kcal are supplied by 350 g of carbohydrates. These calculations are based on the fact that 1 g carbohydrate provides 4 kcal, 1 g fat supplies 9 kcal and 1 g protein gives rise to 4 kcal. Thus the requirements calculated in Table 36.16 may be rewritten as in Table 36.17.

4. Third Step: General Composition of Food
The third step is to calculate how these proximate principles are supplied as common foodstuffs. For this exercise we should familiarize with the nutritive value of foodstuffs. A simplified version is given in Table 36.18. Detailed values are shown in the Appendix VI of this book.

### Table 36.16. First step in the prescription of diet

5. Fourth Step: Determine the Items of Food
Knowing the requirement (Table 36.17) and the nutritive value of foodstuffs (Table 36.18), it is possible to write down the items of the food. A fundamental principle of dietetics is the "food exchange". It is very useful for calculation of the proximate principles. Accordingly, foods with similar nutrient composition are grouped together. This is also useful to provide variety in the food.

### Table 36.19. Food exchange system

<table>
<thead>
<tr>

</table>
energy and proteins. They are nutritionally equivalent. "Legume-pulse exchange system" is also described in Table 36.19.

7. Mutual Supplementation of Cereals and Pulses

Although protein content of pulses is more than cereals, average Indian diet contains more cereals, and hence proteins are mainly supplied by cereals. But pulses give good quality proteins.

A judicious combination of cereals and pulses provide all the essential amino acids (pulses are deficient in methionine, while cereals lack in lysine). An accepted formula is that the food should contain pulses and cereals in the ratio of 1:5 to provide good quality proteins.

Supplementing the cereals with animal proteins is certainly good to improve the quality, but at a higher cost. Fruits and vegetables will provide vitamins and minerals. Vitamin A is available in ripe mango, papaya, carrot, beetroot, and other leafy vegetables. B complex vitamins may be supplied by cereals (parboiled rice, whole wheat powder) and green leafy vegetables. Major sources of calcium are milk, cereals, pulses and green leafy vegetables. Iron is mainly supplied by pulses, cereals, vegetables, meat and liver. Jaggery is a good source for iron. Jaggery is, therefore, superior to refined sugar, especially for children. Milk is a very poor source for iron.

8. Prescribing a Normal Diet

Now we can assemble this knowledge to prepare a diet to suit the requirements given in Table 36.17. The result is given in Table 36.20. This will satisfy the requirements regarding protein (60 g), fats (35 g), calories (2000 kcal), calcium (400 mg) and iron (25 mg). See that cereals–pulses ratio is maintained at 5:1. When calories alone are to be increased, as in the case of a person having severe muscular exercise, tubers and roots will serve this purpose.

9. Fifth Step: Three Meals per Day

The total quantities of proximate principles, thus calculated are divided into breakfast, lunch and supper. The basic principles are summarized in Box 36.3.

10. Diet for Patients with Diabetes

Management of diabetes gives great emphasis for dietary control and exercise. The main aim is to keep the blood sugar level as far near the normal values, for as many hours, as possible in a day. The overall blood glucose level will be increased if there is a steep rise in blood sugar after every meal. Therefore, to maintain the average value near normal, we should reduce the postprandial hyperglycemia. This aim is achieved by:

a. giving a diet having low glycemic index, so that elevation in blood sugar is minimal.

b. giving the total calories in small divided doses, so that small quantity of food is taken at frequent intervals.

### Box 36.3. Important Points for Prescribing a Diet

1. It should be a balanced, well planned diet containing all essential nutrients.
2. The diet should be simple, locally available, palatable and digestible.
3. Adequate protein content with essential amino acids should be supplied. This is achieved by a cereal-pulse mixture with additional animal proteins, if necessary.
4. Calorie intake should be correct and should balance energy expenditure.
5. Special care should be taken to see that adequate quantity of calcium and iron are obtained from the diet. The absorption of these minerals is reduced by other factors in Indian diet.
6. Should have variety and should not differ very much from the habitual diet of the person.
7. Should provide adequate roughage.
Glycemic index

It is assessed by the glucose tolerance test (the glycemic response) after the particular diet and comparing it with a reference meal. The reference meal is always taken as 50 g of glucose (Fig. 36.5).

\[
\text{Index} = \frac{\text{Incremental area under glucose tolerance curve after 50 g test meal}}{\text{Incremental area under curve after 50 g of reference meal (glucose)}} \times 100
\]

Simple carbohydrates such as glucose or sugar will have a high glycemic index. But the same quantity of complex carbohydrates (such as starch) will not increase the blood sugar as much. Because, digestion and absorption are slow, with minimal increment in blood sugar. The glycemic index of complex carbohydrate is lesser than cane sugar.

As a general rule, the glycemic index of carbohydrate is lowered if it is combined with protein, fat or fiber, preferably at least two of the three. The glycemic indices of some of the foods are shown in Table 36.21.

Although ice cream contains sugar, it has a low glycemic index, because it contains a lot of fat which prevents absorption. Thus ice cream may be occasionally consumed by diabetic patients.

Table 36.21. Glycemic index of food items

</tbody>
</table>

The calorie requirement is distributed into proximate principles in the following manner for a diabetic patient: Carbohydrate 60-70%, fat 15-25% and protein 15-20%. Other general principles for prescribing a diabetic diet are:

a. Sugar, sweet and refined carbohydrates are avoided.
b. Leafy vegetables are increased, and tubers are restricted.
c. Frequent small meals are prescribed, with distribution of calories such that, breakfast 15%, mid-morning snack 5%, lunch 30%, evening tea 10%, dinner 35%, bedtime snack 5%.

Total Parenteral Nutrition (TPN)

In patients who cannot (unconscious; removal of large part of gut) or should not (major trauma or surgery) use their gastrointestinal tract, total parenteral feeding has to be resorted. It contains glucose and amino acids. About 10-30% glucose, 1-1.5 g/kg body weight protein, a fat emulsion containing 1-4 g fat/kg body weight, along with multivitamins and trace element solution are commonly used. The solution should also contain adequate amounts of sodium, potassium, calcium and magnesium. The solution may be infused through one of the large vessels like subclavian vein or superior vena cava, where the blood flow is sufficient to dilute the hypertonic solution. This procedure is known as total parenteral nutrition (TPN) or intravenous hyperalimentation.
Detoxification and Biotransformation of Xenobiotics

CHAPTER 37

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Detoxification mechanisms
2. Phase one reactions
3. Oxidation, reduction, hydrolysis
4. Phase two reactions
5. Glucuronic acid, sulphate, methyl
6. Phase three reactions

Biotransformation is the process whereby a substance is changed from one chemical to another by a chemical reaction within the body. For some drugs, it is not the absorbed drug, but a metabolite that has therapeutic action.

Biotransformation also serves as an important defense mechanism in that toxic xenobiotics and metabolites are converted into less harmful substances and substances that can be excreted from the body.

In general, biotransformation reactions generate more polar metabolites, that are readily excreted from the body. The liver plays the most important role in the biotransformation reactions.

The biochemical processes whereby the noxious substances are rendered less harmful and more water soluble, are known as detoxification. Lipophilic toxicants are hard for the body to eliminate and can accumulate to hazardous levels.

Xenobiotics are compounds which may be accidentally ingested or taken as drugs or compounds produced in the body by bacterial metabolism (Greek, xenos = strange).

Biotransformation is not exactly synonymous with detoxification, since in many cases, the metabolites are more toxic than the parent substance. This is known as bioactivation or toxification. An example is the biotransformation of vinyl chloride to vinyl chloride epoxide, which covalently binds to DNA and RNA, a step leading to cancer of the liver. The compounds that are detoxified include:

a. Compounds accidentally ingested like preservatives, food additives and adulterants.
b. Drugs taken for therapeutic purposes.
c. Compounds produced in the body which are to be eliminated, e.g. bilirubin and steroids. Bilirubin is toxic to the brain of newborns and may cause irreversible brain injury. Biotransformation of the lipophilic bilirubin molecule in the liver results in the production of water-soluble (hydrophilic) metabolites excreted into bile.
d. Compounds produced by bacterial metabolism, e.g. amines produced by decarboxylation of amino acids:

<table>
<thead>
<tr>
<th>Amino Acid</th>
<th>Metabolite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Histidine</td>
<td>Histamine</td>
</tr>
<tr>
<td>Lysine</td>
<td>Cadaverine</td>

<tr>
<td>Ornithine</td>
<td>Putrescine</td>
</tr>
<tr>
<td>Tyrosine</td>
<td>Tyramine</td>
</tr>
<tr>
<td>Tryptophan</td>
<td>Tryptamine</td>
</tr>
</tbody>
</table>

The transformation of a specific xenobiotic can be either beneficial or harmful, and perhaps both depending on the dose. A good example is the biotransformation of acetaminophen, a commonly used drug to reduce pain and fever. It normally undergoes rapid biotransformation with the metabolites quickly eliminated in the urine and feces; hence no toxicity is observed.

But at high doses, the normal level of enzymes may be saturated. The excess acetaminophen undergoes additional biosynthetic pathway, which produces a metabolite that is toxic to the liver.

Cytochrome P450 Enzyme Systems
The cytochrome P450 enzymes are involved in the biotransformation reactions. They are heme-containing enzymes, localized in the endoplasmic reticulum of liver. They are so named, because they absorb light at wavelength of 450 nm, when exposed to carbon monoxide. They are mono-oxygenases

\[
R-H + O_2 + NADPH + H^+ \rightarrow R-OH + H_2O + NADP^+
\]

NADPH (and not NADH) is the co-enzyme for all the P450 enzymes. Electrons are transferred from
NADPH to cytochrome P450. This leads to the reductive activation of molecular oxygen. One atom of oxygen is inserted into the substrate.

Cytochrome P450 contains phosphatidyl choline. Almost all common drugs are metabolized by the P450 system. There are about 150 isoforms of the P450 enzymes. They are classified according to structural homology, into family, subfamily etc. CYP is the accepted abbreviation. For example, CYP1A1 denotes that it is a cytochrome P450, belonging to family 1 and subfamily A, and is the first member in that subfamily. The genes of the corresponding proteins are described with the same name, except that genes are written with italics.

They are inducible enzymes. Phenobarbital causes increased activity of P450. The anticoagulant Warfarin is metabolized by CYP2C9. If the same patient is taking phenobarbitone, the enzyme is induced, the level of the enzyme is increased, warfarin is broken down quickly, and the dose of warfarin becomes inadequate. Similarly ethanol induces CYP2E1, which metabolises many carcinogens. Thus, the risk of carcinogenicity is increased after the use of ethanol.

CYP1A1 and some other members of the family are used in the metabolism of polycyclic aromatic hydrocarbons (PAHs). So this group is sometimes called aromatic hydrocarbon hydroxylases (AHHs). Cigarette smoke contains various aromatic hydrocarbons, these are activated by AHHs.

Some of the isoforms of the enzyme exhibit low catalytic activity (polymorphism). This explains the variation in drug responses among different persons. For example, there are 3 alleles for CYP2A6, which catalysate nicotine of tobacco. The person with the inactive allele is protected against addiction to tobacco.

The P450 enzymes are seen in many tissues, including adrenal glands, where they are present both in mitochondria and in microsomes. The mitochondrial P450 enzymes utilize NADPH linked flavoprotein, adrenodoxin reductase, and a non-heme iron-sulfur protein, adrenodoxin. They are mainly involved in steroid biosynthesis.

**Phases of Detoxification Processes**

Biotransformation reactions are usually classified as Phase one and Phase two reactions.

**Phase one** is the alteration of the foreign molecule, so as to add a functional group, which can be conjugated in phase 2. Phase 1 reactions result in the formation of compounds with decreased toxicity (detoxification). Sometimes this may result in increased toxicity (entoxification), e.g. Methanol to formic acid.

The phase 1 reactions include hydroxylation, oxidation, reduction, hydrolysis, dealkylation, epoxidation, etc.

The products of metabolic transformations are either excreted directly or undergo further metabolism by phase two reactions. They involve conjugation with a conjugating agent, thus converting lipophilic compounds into water soluble, easily excretable forms. Phase 2 reactions are sulfation, acetylation, methylation and conjugation with glucuronic acid, glutathione or glycine.

In some instances, products of phase 2 reactions may further be metabolized by phase three reactions.

**PHASE ONE REACTIONS**

1. **Oxidative Reactions**

   i. It may be either aromatic or aliphatic hydroxylation. The reactions also include sulfoxidation, N-oxidation and epoxidation.

   ii. For example, toluene is hydroxylated to benzyl alcohol by mixed function oxidase system (Fig. 37.1).

   iii. Sometimes both phase 1 and 2 reactions are necessary. The biotransformation of benzene requires both Phase one and Phase two reactions. Benzene is biotransformed initially to phenol by a Phase one reaction (oxidation). Phenol has the functional hydroxyl group that is then conjugated by a Phase two reaction (sulphation) to phenyl sulfate (Fig. 37.2).

   iv. The oxidation and detoxification of alcohol is also an important function of the liver. Two enzymes are involved in this process: alcohol dehydrogenase oxidises alcohol to aldehyde; and aldehyde dehydrogenase oxidises aldehyde to acid (Fig. 37.3). The alcohol
dehydrogenase is an NAD$^+$ linked enzyme, which is located in the cytosol. Aldehyde dehydrogenase is an NAD$^+$ dependent mitochondrial enzyme.

v. Oxidation of some compounds may result in production of substances which are more toxic, e.g.

Methanol $\rightarrow$ Formic acid
Ethylene glycol $\rightarrow$ Oxalic acid

2. Reduction Reactions

Some of the reductases also contain cytochrome P-450 and are flavoproteins in nature. The major group of compounds which are reduced and detoxified by the liver are nitro compounds. These are reduced to their amines, while aldehydes or ketones are reduced to alcohols. An example is the reduction of nitrobenzene to aniline (Fig. 37.4). Other examples are:

Picric acid $\rightarrow$ picramic acid
Para-nitrophenol $\rightarrow$ para-aminophenol

Aspirin is the drug most widely used in clinical practice. It has analgesic, antipyretic and anti-atherogenic activities. It was synthesized by Charles Gerhardt in 1853. Felix Hoffmann used it as a pain killer for the first time. Salicylic acid was known as sprinic acid, as it was produced from Spirea plants. So acetyl salicylic acid was first named as acetyl-sprin, and later, shortened to aspirin.

<td>Acetyl CoA</td>
</tr>
</tbody>
</table>

3. Hydrolysis

Hydrolysis is a chemical reaction in which the addition of water splits the toxicant into two fragments or smaller molecules. The hydroxyl group (OH-) is incorporated into one fragment and the hydrogen atom is incorporated into the other. Esters, amines, hydrazines, amides, glycosidic bonds and carboxylates are generally biotransformed by hydrolysis, e.g. aspirin, acetanilide, procaine, xylocaine, aliphatic esters, di-isopropyl fluoro-phosphate (DFP), etc. (Fig. 37.5).

**Aspirin** is the drug most widely used in clinical practice. It has analgesic, antipyretic and anti-atherogenic activities. It was synthesized by Charles Gerhardt in 1853. Felix Hoffmann used it as a pain killer for the first time. Salicylic acid was known as sprinic acid, as it was produced from Spirea plants. So acetyl salicylic acid was first named as acetyl-sprin, and later, shortened to aspirin.

---

**Fig. 37.3. Oxidation of alcohol groups**

**Fig. 37.4. Phase one; reductive reaction**

**Fig. 37.5. Phase one. Examples of hydrolysis**

**Table 37.1. Phase two; usual conjugating agents**
PHASE TWO REACTIONS; CONJUGATIONS

i. A xenobiotic that has undergone a Phase one reaction is now a new metabolite that contains a reactive chemical group, e.g. hydroxyl \((-\text{OH})\), amino \((-\text{NH}_2\)) and carboxyl \((-\text{COOH})\). These metabolites must undergo additional biotransformation as a Phase two reaction.

ii. Phase two reactions are conjugation reactions, that is, a molecule normally present in the body is added to the reactive site of the Phase one metabolite. In most cases, the conjugation will make the compounds nontoxic and easily excretable.

iii. Conjugating agents and their active forms are shown in Table 37.1. Glycine and glutamine can also act as conjugating agents.

1. Glucuronic Acid

Glucuronide conjugation is the most common Phase two reactions. Bilirubin is a good example for a compound conjugated and excreted as its glucuronide. Glucuronic acid can conjugate with hydroxyls (both phenolic and alcoholic), carbonyl, sulphydryl and amino compounds.

![Glucuronide conjugation](image)

</tr>
<tr>
<td>Amines</td>
<td>Amide</td>
<td>N-glucuronides</td>
</tr>
</tbody>
</table>

2. Sulfate Conjugation

In general, sulfation decreases the toxicity of xenobiotics. The highly polar sulfate conjugates are readily excreted through urine. Often glucuronidation or sulfation can conjugate the same xenobiotics. Phenolic and alcoholic compounds are conjugated with sulfate. The enzyme is sulfo-transferase and the sulfate group is transferred from PAPS (phospho adenosine phospho sulfate, see Chapter 15).

\[
\begin{align*}
\text{R–OH + PAPS} & \rightarrow \text{R–O–SO}_3^- + \text{PAP} \\
\text{Phenol + PAPS} & \rightarrow \text{Phenyl sulfate + PAP} \\
\text{Indole + PAPS} & \rightarrow \text{Indoxyl sulfate + PAP}
\end{align*}
\]

Important compounds excreted as their sulfates include steroids and indole compounds.

3. Cysteine and Glutathione

The cysteine is derived from glutathione, which is the active conjugating agent. The reaction is given...
in detail in Figure 37.6. Alkyl or aryl halides, epoxides and alkenes are detoxified in this manner.

4. Acetylation
Conjugation with acetic acid is taking place with drugs like sulfanilamide, isoniazid and PAS (para-amino salicylic acid) (Fig. 37.7).

5. Conjugation with Glycine
Benzoic acid is conjugated with glycine to form **hippuric acid** (benzoyl glycine), which is excreted in urine (Fig. 37.8).

6. Conjugation with Glutamine
Similarly, Phenyl acetic acid is conjugated with glutamine to form **phenyl acetyl glutamine** (Fig. 37.8).

7. Methylation Reactions
   i. Amino, hydroxy or thiol groups are methylated. **S-adenosyl methionine** (SAM) is the methyl donor and the enzyme is usually O-methyl transferase.
   
   ii. For example, catechol-O-methyl transferase converts epinephrine to metanephrine. Pyridine is excreted as N-methyl pyridine.
   
   iii. Mercapto ethanol is excreted as 5-methyl mercapto ethanol. Transmethylation reactions are given in detail in Table 15.1.
   
   iv. However, methylation decreases the water solubility rather than increasing it. Metals like mercury may be methylated, making them more lipophilic, increasing permeability and causing neurotoxicity.

**PHASE THREE REACTIONS**

i. Phase 3 reactions are not very common. A typical example is further conjugation with glutathione.

ii. The xenobiotics that enter the body are mostly drugs and they are detoxified by the enzymes concerned with drug metabolism. Induction of cytochrome P-450 system may even produce unwanted effects in some persons. For example, induction of ALA synthase by barbiturates will precipitate attacks in acute intermittent porphyria (Chapter 21).

iii. Beneficial effect of induction is utilized in newborns to induce glucuronyl transferase enzyme by barbiturates.

iv. In some cases, the xenobiotics may be converted to harmful compounds by the cytochrome P450-dependent oxygenases, e.g. Benzopyrene is converted to a carcino gen by epoxidation.

v. Effect of a particular drug may vary from person to person. The drug metabolizing enzymes may show genetic variation. This may lead to decreased, increased or absent expression of enzyme activity. Some people who can metabolize the drugs sluggishly, may show toxic manifestations with normal doses of the drug.

**Related Topics**
Please see detoxification of free radicals (Chapter 20) and liver functions tests (Chapter 26).
CHAPTER 38

Environmental Pollution and Heavy Metal Poisons

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Corrosives
2. Irritants
3. Heavy metal poisons
4. Lead, Mercury, Aluminium
5. Pesticides and insecticides
6. Occupational or industrial hazardous agents
7. Air pollutants
8. Toxic substances in foodstuffs

Man has tried to change the environment in different ways from the days when he was a cave dweller. Any substance present in the environment, which may produce abnormality in metabolism or alter the well being of organism, is called an environmental pollutant.

A poison is a substance which causes death or harm if introduced in the living body or brought into contact with parts of the body.

Lethal doses (per kg body weight) of some toxic substances are: Cyanide = 1 mg/kg body weight; Morphine = 25 mg/kg; Aspirin = 500 mg/kg; Ethyl alcohol = 10 g/kg.

CORROSIVES
These are strong acids (sulfuric acid, hydrochloric acid); strong alkalies (sodium hydroxide, ammonia); and salts (zinc chloride, potassium chromate).

They remove water from the tissues, coagulate the cellular proteins and convert hemoglobin into acid hematin.

The cause of death is circulatory collapse and spasm of glottis. Sulfuric acid can be detected from the gastric fluid by reacting with barium chloride to produce a white precipitate of barium sulfate.

Ammonia, potassium hydroxide, sodium hydroxide, calcium hydroxide and ammonium carbonate are the common alkalies encountered. They remove water from the tissues and precipitate proteins.

These can be detected in the gastric juice by reacting with silver nitrate to form silver hydroxide, which forms a brown precipitate. Ammonia is highly neurotoxic (Chapter 14).

Cyanide Poisoning
Cyanide causes tissue anoxia by chelating the ferric ions of the intracellular respiratory enzyme, cytochrome oxidase. Poisoning may be due to suicidal attempts. Industrial exposure may occur in the persons working with hydrocyanic (prussic) acid or with potassium cyanide.

Ingestion of amygdalin, present in kernels of certain fruits (apricots, almonds, peaches) is also a common cause.

Dicobalt edetate (kelocyanor) is the antidote, which chelates the cyanide. Another method is to give sodium nitrite and sodium thiosulfate intravenously. The nitrite converts hemoglobin to methemoglobin. Ferric ion of Met-Hb takes up cyanide as cyan-met-hemoglobin so that cytochrome oxidase is now free of cyanide. Later thiosulphate detoxifies the cyanide by forming thiocyanate, which is excreted. But in practice, death is instantaneous and time may not be available for the treatment.

IRRITANTS
Important chemical irritants are phosphorus, chlorine, bromine and iodine. Metallic irritants are arsenic, antimony, mercury, copper, lead, zinc and silver. Organic irritants from plants include castor, croton, and calotropis.

Phosphorus
It is a poison affecting cellular oxidation. Accidental poisoning in children may occur due to chewing of fireworks or rat poisons. Symptoms resemble acute liver disease. The poison is oxidized in the body.

Neurotoxins
These may act at cerebral level, e.g. opium, alcohol, ether, chloroform, datura, belladona, cannabis, etc. Those acting at spinal level are aconite, quinine and oleander.
HEAVY METAL POISONS

1. Lead Poisoning

A 61-year old male was admitted in a medical college hospital in Bengaluru with typical symptoms of lead poisoning (encephalopathy, nephropathy and anemia). The lead level in blood was over 100 microgram/dl. On detailed questioning, the patient told that he was very particular to take only “pure food” and he was preparing fresh “aatta” (wheat flour). He was powdering wheat on a small hand-mill at his house. The machine had a crusher which was fixed on the pivot by soldering with lead. So for the last 30 years, he was getting daily doses of lead along with his “pure aatta”. The company had already supplied thousands of such instruments throughout the country. All those families might be getting harmful doses of lead!

1-A. Sources of lead poison

i. Lead is the most common environmental poison in India. About 30% of population are already affected by lead poisoning. It is dispersed into air, food, soil and water. Lead poisoning is also included in the class of "summer disease", as increased temperature brings out the dust, and lead particles will also be in the air.

ii. Paint is the major source for exposure, especially in children, as they bite painted toys. US law states that paints should not contain more than 0.06% of lead. But Indian paints, especially cheaper ones may contain up to 30% lead salts. Paint is peeled off as small flakes from walls of living rooms.

iii. Increased content of lead is seen in air, water and vegetables in cities and near highways. This is due to the tetraethyl lead derived from the exhaust of vehicles. Statutory use of lead-free petrol has reduced this type of contamination.

iv. Lead pipes are important sources for contamination.

v. Newspapers and xerox copies contain lead, which is adsorbed to fingertips, and later contaminate foodstuff taken by hands.

vi. One pack of cigarette contains 15 microgram of lead and chronic smokers have higher blood levels of lead.

vii. Lead chromate is commonly used as adulterant in curcumin.

viii. Battery repair, radiator repair, soldering, painting and printing are occupations prone to get lead poisoning.

1-B. Signs and Symptoms of Lead Poisoning

i. Lead is a cumulative poison and is accumulated in tissues over the years. It is not biodegradable. 90% of lead is seen in bones, 9% in blood and 1% in brain and kidneys.

ii. There is no “safe” level in blood; about 10 mg/dl can be tolerated. More than 10 mg/dl in children and more than 25 mg/dl in adults leads to toxic manifestations.

iii. Lead can pass through placenta and milk. Miscarriage, still birth, and premature birth are reported in lead poisoning of mothers.

iv. Developing brains are more susceptible to lead. Permanent neurological sequelae, cerebral palsy and optic atrophy may be seen.

v. In children, mental retardation, learning disabilities, behavioral problems, hyperexcitability and seizures are seen. Even 10 microgram/dl of lead in blood for a long time will reduce I.Q. to 8 points.

vi. Anemia, abdominal colic and loss of appetite are very common.

vii. If the blood level is more than 70 mg/dl, acute toxicity is manifested, as encephalopathy, convulsions, mania, neuropathy, abdominal colic, severe anemia and kidney damage. Discoloration and blue line along the gums are characteristic features of acute lead poisoning.

viii. Lead inhibits heme synthesis. Basophilic stippling of red cells are seen in the peripheral blood and bone marrow smears. This is due to the agglutination of ribosomes. Globin synthesis is adversely affected. Lead particularly inhibits delta amino levulinic acid (ALA) synthase and ALA-dehydratase (see Chapter 21). Lead also inhibits the enzyme ferrochelatase. Life span of RBC is shortened. Anemia enhances lead absorption, lead in turn produces more anemia; thus a vicious cycle is operating. Lead will inhibit absorption of iron and calcium. 1 molecule of lead will inhibit absorption of 1000 molecules of calcium.

1-C. Treatment of Lead Poisoning

Calcium dodecyl edetate (Calcium disodium versenate), penicillamine and dimercaprol (BAL) are used as antidotes. Dimercaptosuccinic acid is a better but costly antidote.

2. Mercury Poisoning

It is the most common industrial poison. The source for poisoning may be elemental, inorganic or organic mercury.

2-A. Elemental mercury

Hazard may come from inhalation of mercury vapor from broken thermometers, sphygmomanometers or
from dental amalgam. In acute poisoning pulmonary edema and encephalopathy may result. A classical triad of (a) oral lesions (gingivitis, salivation and stomatitis), (b) tremor and (c) psychological changes (insomnia, shyness, emotional instability, memory loss) are the hallmark of chronic elemental mercury poisoning. This is called erethism.

2-B. Inorganic Mercury
Poisoning may arise from calomel (cathartic), topical medicines and in plastic industry. Acute effects include gingivitis, gastritis, vomiting and pulmonary edema. In chronic cases, erethism, especially the neuropsychiatric manifestations predominate.

2-C. Organic Mercury
Poisoning may occur from paints, fungicides and cosmetics. From mercury salt wastes, the bacteria synthesise methyl mercury ($\text{CH}_3\text{Hg}^+$). This then enters into the fish. Eating of such fish is the most common cause for organic mercury poisoning.

In 1953, in Minamata Bay, Japan, industrial effluent caused methyl mercury poisoning, an epidemic lasting for several years. Organic mercury poisoning is thereafter called Minamata disease.

The classical triad of methyl mercury exposure is dysarthria, ataxia and visual field constriction. In severe cases, toxic encephalopathy, sensory neuropathy, intention tremor, hearing loss and spasticity may also be seen. Laboratory investigation findings are:

i. Normal level of mercury in blood is less than 1 mg/dl. When it is increased to 2-5 mg/dl, symptoms of toxicity appear. A level of 15 mg/dl is fatal.

ii. Urinary excretion of mercury is elevated, especially in chronic poisoning.

iii. Hair analysis can detect organic mercury compounds. Dimercaprol derivatives, D-penicillamine, and N-acetyl cysteine can increase the excretion of mercury and are useful in treatment.

3. Aluminium Toxicity
i. Aluminium is the third most abundant element after oxygen and silicon in earth’s crust. Exposure is from packing and building materials, paint pigments, insulating materials, cosmetics, antacids, and aluminium cooking vessels.

ii. An average Indian consumes 1-10 mg of aluminium per day, but only part of it is absorbed. Tolerable upper limit of absorption is 1 mg/day. Only up to 100 microgram/day can be eliminated through urine. If intake is more than 100 mg/day, toxicity results.

iii. Aluminium stimulates production of free radicals. It prevents absorption of calcium, phosphorus and iron. It also interferes with heme synthesis.

iv. Aluminium precipitates Alzheimer precursor proteins and may lead to Alzheimer’s disease. Aluminium is implicated in degeneration of dendrites. It is also involved in Parkinson’s disease.

v. Osteomalacia and microcytic hypochromic anemia are other manifestations of toxicity.

4. Arsenic Toxicity
The oxides of arsenic are commonly used as fruit sprays, pesticides, rat poisons, etc. It acts on sulfhydryl enzymes and interferes with cell metabolism. It may also cause intravascular hemolysis, which leads to hemoglobinuria. The trivalent or pentavalent organic arsenic compounds are less toxic than inorganic compounds. The symptoms are anaphylactic reactions or later development of agranulocytosis, hepatitis, jaundice and encephalitis.

PESTICIDES AND INSECTICIDES
DDT (dichlorodiphenyl trichloro ethane)
It is fat soluble and deposited in the adipose tissue. It is not excreted. Thus concentration inside the body goes on increasing. The DDT used in North America as pesticide during 1970s has reached Antarctica and reduced the thickness of shell of eggs of penguins. Even though DDT is banned in many countries, it is still available in India. Many antifungal agents sprayed on fruits are having long term effects of depressed spermatogenesis and fertility.

Organophosphorus Compounds
Organophosphorus (ORP) and organocarbamates (ORC) are the common pesticides and organo sulfur compounds (dithiocarbamates) are fungicides. Organophosphorus compounds, Parathion and Malathion are powerful neurotoxic agents. They inhibit acetyl choline esterase through phosphorylation of the active center of the enzyme. Hence acetylcholine accumulates in the nerve endings. Thus the transfer of nerve impulse across synapses and at the nerve-muscle junction is
prevented. Diagnosis depends on the estimation of cholinesterase in serum and RBC. The antidote is atropine sulfate and cholinesterase re-activators (diacetyl monoxime or pralidoxime).

**OCCUPATIONAL AND INDUSTRIAL HAZARDS**

**Polychloro-biphenyls**
They are widely used in various industries, can mimic thyroid hormones. Bisphenols from plastic containers leach out into drinking water. Vinyl phenols are dissolved from PVC pipes. These chemicals will lead to decrease in fertility and alteration in behavior.

**Freon and Chlorofluoro Methane**
CF₂Cl₂ (CFC) and CFCl₃ are used in refrigerators and spray-cans. They are photo-dissociated to chlorine atoms. When chlorine reaches upper atmosphere, it destroys the ozone layer that has been protecting the biosphere against excessive radiation, ever since life emerged.

**Methanol**
It is the organic solvent widely used in paints and anti-freezes. It may be consumed in place of ethanol as a substitute. Alcohol dehydrogenase converts methanol to formaldehyde. It is more toxic than ethanol. Optic neuritis and blindness is the characteristic toxicity. The treatment is to give large doses of ethanol, which is preferentially oxidized in the body so that formaldehyde formation is reduced.

**AIR POLLUTANTS**
The atmosphere contains mostly nitrogen (78.09%) and oxygen (20.94%), carbon dioxide (0.03%), and water vapor. The permissible level of total suspended particles (TSPs) is 230 mg/cu.m.

A chemical other than those conventionally accepted in the composition of clean air is called a Contaminant. A contaminant that occurs in the atmosphere in sufficiently high concentrations to cause an adverse effect is called a Pollutant.

The main natural sources of pollution are due to volcanic eruption, forest fires, dust storms and air borne particles. In addition to dissolved gases, suspended particulate matter like dust and soot, also adds to the contamination of air. They range in size from 1 to 10 microns in diameter.

The major artificial sources of pollution arise due to emissions from automobiles, industry and power plants. These are carbon dioxide, carbon monoxide, hydrocarbons, oxides of nitrogen, oxides of sulfur and lead.

The poisonous mixture of smoke, fog, air and other chemicals is called smog. The chemically reducing smog is derived from the combustion of coal and oil, and contains sulfur dioxide (SO₂), sulfur trioxide (SO₃), mixed with soot. SO₂ and SO₃ in presence of atmospheric water vapor, become sulfurous and sulfuric acids, respectively. This is the precursor of acid rain that may be carried by wind to long distances.

Chronic respiratory symptoms are associated with sulfur oxide or participates in air. Exacerbations of bronchitis were associated with high concentrations of smoke and sulfur oxide. Children living in polluted areas show diminished ventilatory function when compared with their counterparts living in less polluted areas.

Heart diseases are also related to pollutants such as ozone, sulfur dioxide, sulfates and cadmium in the air. High level of carbon monoxide decreases ability to concentrate and decreases visual threshold. Inhalation of air borne lead can cause neurological disturbances.

**Industrial Pollution**
Dramatic and disastrous episodes of air pollution have been documented in many industrialized centers in the world. An example was the London Fog of 1952, in which approximately 4000 deaths occurred over a period of 2 weeks, following 5 days of severe cold and dense fog. Another such event was the Bhopal gas tragedy in December 1984 which claimed thousands of lives due to methyl isocyanate (MIC) poisoning.

**Passive Cigarette Smoking**
The particulate load in a household is directly proportional to the number of cigarette smokers living at home. Increased prevalence of respiratory illnesses and reduced levels of pulmonary function measurements have been found in children of smoking parents. Studies have also concluded that lung cancer risk is higher in non-smokers who live under the same roof with smokers.

**Other Obnoxious Indoor Agents**
Common industrial pollutants and their effects are listed in Table 38.1.

**TOXIC SUBSTANCES IN FOODSTUFFS**
These may be considered under the following headings.
Chapter 38; Environmental Pollution and Heavy Metal Poisons

1. Toxins normally present in plants.
2. Contamination occurring during cultivation.
3. Products of post-harvest period.
4. Chemical contaminants during food processing.
5. Food adulterants.
6. Toxins entering during or after cooking.

1. **Toxins Normally Present in Plants**
   i. **Protease inhibitors:** Many legumes (soybean, field bean, peanut), cereals (corn) and tubers (potato, sweet potato) contain trypsin inhibitors. They are destroyed by cooking. But partially cooked food may have this activity, inhibiting digestion and absorption of amino acids.
   
   ii. **Goitrogens:** They prevent iodine uptake or utilization by thyroid gland. Thio-oxazolidone is present in cabbage, radish, turnip and brussel sprouts. Thiocyanates and iso-thiocyanates are seen in mustard and other oilseeds. Polyphenolic glycosides are present in the red skins of groundnut and almonds. All these compounds have goitrogenic effect.
   
   iii. **Anti-vitamins:** Orange peel, used in making orange marmalade, contains citral, which inhibits vitamin A activity. Linseed oil, which contains linetin, interferes with pyridoxine utilization. Black berries and red cabbage contain thiaminase, which destroys vitamin B1. Raw eggs, containing avidin, can lead to biotin deficiency.
   
   iv. **Cyanogenic Glycosides:** Cereals (sorghum), legumes (lima beans) and tubers (tapioca or cassava) contain cyanogenic compounds, which on hydrolysis produce hydrocyanic acid. Hence, they are highly toxic when taken raw. Cattle and sheep eating tapioca leaves often get acute fatty degeneration of liver with fatal outcome. The toxins can be removed by cooking and decanting the supernatant water.
   
   v. **Favism:** Ingestion of uncooked broad bean (vicia fava) may cause **hemolytic anemia** in susceptible persons with glucose-6-phosphate dehydrogenase (GPD) deficiency (see Chapter 23). The toxic glycoside is known as vicin. Cooking and decanting will remove the toxins.
   
   vi. **Alkaloids:** Some mushrooms contain poisonous alkaloids. In small quantities, they produce nausea, vomiting, diarrhea, etc. In large quantities, it may produce acute necrosis of liver and death may result.
   
   vii. **Pressor Amines:** They increase the blood pressure. Histamine, tyramine, tryptamine, serotonin and epinephrine are present in significant quantities in plantains, banana and cheese. Tyramine is present in cheese, wine and beer. Usually these are detoxified by mono amine oxidase (MAO) enzyme. But in persons taking MAO-inhibitors, their consumption may produce hypertension and headache.

2. Contamination Occurring During Cultivation
This is due to pesticides and insecticides. These toxins could be removed by repeated washing and by peeling of outer layers of vegetables and fruits.

3. Storage Contamination
   i. Fungal infections: During post-harvest storage, contamination with fungus is very common. *Aspergillus flavus* produces aflatoxins, which are hepatotoxic and carcinogenic (Chapter 51). The fungus grows in moist conditions in groundnut, coconut, rice, maize, wheat, etc. Maximum permissible limit of aflatoxin contamination is 0.05 ppm.
   ii. Ergot (*Claviceps purpurea*): It is the fungus that usually grows in moist food grains (rye, millet, wheat, barley, bajra). Ergotamine, ergotoxin and ergometrin are present in this fungus (Ergometrin is clinically used to prevent postpartum hemorrhage). The toxins may produce peripheral vascular contraction, causing painful cramps, gangrene in extremities and convulsions. The disease is called ergotism.

4. Contamination During Food Processing
   Mineral Oils: Petroleum products are used to extract oil from seeds. These solvent residues may remain in the extracted oil. Mineral oils have hepatotoxic and carcinogenic properties.

5. Adulterants
   i. Lathyrism: It is characterized by paralysis of lower limbs. It is seen in persons consuming large quantities of *Lathyrus sativus* (Khesari dal). Khesari dal is widely used to adulterate ordinary dal, and hence the disease may be seen sporadically all over India. Neurotoxins present in lathyrus cause damage of upper motor neurons. There is exaggerated knee jerk, ankle clonus, scissor gait and spastic paralysis. The toxic principle from *lathyrus sativus* is identified as beta oxalyl amino alanine (BOAA), having the structure COOH--CH(NH2)--CH2--NH--CO--COOH
   BOAA also inhibits lysyl oxidase, resulting in reduced cross-linking in collagen. Thorough cooking and decanting the supernatant two or three times will remove these toxins (leaching out the toxin by hot water). Ironically, the protein content in Khesari dal is of very good quality.
   ii. Argemone oil: Mustard oil may be adulterated with argemone oil. This is from a wild plant, *Argemone mexicana*. Argemone seeds are similar to mustard seeds, and oil from both seeds are similar in consistency. Hence adulteration is easy. Argemone oil contains the alkaloid, sanguinarine which causes vomiting, diarrhea, congestive cardiac failure and edema. It is then called epidemic dropsy.

6. Toxins entering during food preparation
   Mono sodium glutamate (Aginomoto): It is a common food additive. Packets of mono sodium glutamate carry the statutory warning that it is unsuitable for children below the age of 5. It produces transient symptoms like numbness and palpitation. It may deteriorate mental alertness in children.

Ethanol metabolism (Chapter 10); Carbon monoxide (Chapter 22); Detoxification and Xenobiotics (Chapter 37); Free Radicals (Chapter 20); Environmental and Chemical Carcinogens (Chapter 51).
CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Purines and pyrimidines
2. Nucleosides and nucleotides
3. De novo synthesis of purine nucleotides
4. Degradation of purine nucleotides
5. Uric acid and gout
6. De novo synthesis of pyrimidines
7. Disorders of pyrimidine metabolism.

In 1868, Frederick Miescher isolated nucleic acid (then called nuclein) from pus cells. Albrecht Kossel (Nobel prize, 1910) differentiated RNA and DNA in 1882. In 1906, Kossel described the 4 bases in nucleic acids.

Nucleotides are precursors of the nucleic acids, deoxy-ribonucleic acid (DNA) and ribonucleic acid (RNA). The nucleic acids are concerned with the storage and transfer of genetic information. The universal currency of energy, namely ATP, is a nucleotide derivative. Nucleotides are also components of important co-enzymes like NAD+ and FAD, and metabolic regulators such as cAMP and cGMP.

Composition of Nucleotides
A nucleotide is made up of 3 components:
- Nitrogenous base, (a purine or a pyrimidine)
- Pentose sugar, either ribose or deoxyribose;
- Phosphate groups esterified to the sugar.

When a base combines with a pentose sugar, a nucleoside is formed.

When the nucleoside is esterified to a phosphate group, it is called a nucleotide or nucleoside mono-phosphate. When a second phosphate gets esterified to the existing phosphate group, a nucleoside diphosphate is generated. The attachment of a 3rd phosphate group results in the formation of a nucleoside triphosphate. The nucleic acids (DNA and RNA) are polymers of nucleoside mono-phosphates.

Bases Present in the Nucleic Acids
Two types of nitrogenous bases; the purines and pyrimidines are present in nucleic acids.

Fig. 39.1. Structure of purines

Fig. 39.2. Minor bases seen in nucleic acids
1. Purine Bases
The purine bases present in RNA and DNA are the same; adenine and guanine. Adenine is 6-amino purine and guanine is 2-amino, 6-oxypurine. The numbering of the purine ring with the structure of adenine and guanine are shown in Figure 39.1.

2. Minor Purine Bases
These bases may be found in small amounts in nucleic acids and hence called minor bases. These are hypoxanthine (6-oxopurine) and xanthine (2, 6-di-oxopurine) (Fig. 39.2). Uric acid (2,6,8-tri-oxopurine) is formed as the end product of the catabolism of other purine bases. It can exist in the "enol" as well as "keto" forms (tautomeric forms) (Fig. 39.2). Keto form is by far the predominant type under physiological conditions.

3. Pyrimidine Bases
The pyrimidine bases present in nucleic acids are cytosine, thymine and uracil. Cytosine is present in both DNA and RNA. Thymine is present in DNA and uracil in RNA. Structures are shown in Figure 39.3. See also Box 39.1.

A few other modified pyrimidine bases like dihydro-uracil and 5-methyl cytosine are also found rarely in some types of RNA (Fig. 39.4).

Nucleosides
i. Nucleosides are formed when bases are attached to the pentose sugar, D-ribose or 2-deoxy D-ribose (Fig. 39.5).

ii. All the bases are attached to the corresponding pentose sugar by a beta-N-glycosidic bond between the 1st carbon of the pentose sugar and N9 of a purine or N1 of a pyrimidine.

iii. The deoxy nucleosides are denoted by adding the prefix d- before the nucleoside.
iv. The carbon atoms of the pentose sugar are denoted by using a prime number to avoid confusion with the carbon atoms of the purine or pyrimidine ring (Fig. 39.6). The names of the different nucleosides are given in Table 39.1.

v. Nucleosides with purine bases have the suffix -sine, while pyrimidine nucleosides end with -dine.

vi. Uracil combines with ribose only; and thymine with deoxy ribose only (Table 39.1).

### Nucleotides

i. These are phosphate esters of nucleosides. Base plus pentose sugar plus phosphoric acid is a nucleotide.

ii. The esterification occurs at the 5th or 3rd hydroxyl group of the pentose sugar. Most of the nucleoside phosphates involved in biological function are 5'-phosphates (Table 39.2).

iii. Since 5'-nucleotides are more often seen, they are simply written without any prefix. For example, 5'-AMP is abbreviated as AMP; but 3' variety is always written as 3'-AMP.

iv. Moreover, a base can combine with either ribose or deoxy ribose, which in turn can be phosphorylated at 3' or 5' positions. One purine and one pyrimidine derivative are given as examples in Table 39.3.

</table>
v. Many co-enzymes are derivatives of adenosine monophosphate. Examples are NAD⁺, NADP, FAD and Co-enzyme A.

vi. Nucleotides and nucleic acids absorb light at a wavelength of 260 nm; this aspect is used to quantitate them. As nucleic acids absorb ultraviolet light, chemical modifications are produced leading to mutation and carcinogenesis.

Nucleoside triphosphates

i. Corresponding nucleoside di- and tri-phosphates are formed by esterification of further phosphate groups to the existing ones. In general, any nucleoside triphosphate is abbreviated as NTP or d-NTP (See Table 39.4).

ii. Nucleoside diphosphate contains one high energy bond and triphosphates have 2 high energy bonds. ATP is the universal energy currency (Fig. 39.7). It is formed during oxidative processes by trapping the released energy in the high energy phosphate bond. More details on high energy bonds are given in Chapter 19.

iii. A phosphodiester linkage may be formed between the 3’ and 5’ positions of ribose group. Such compounds are called cyclic nucleotides (Fig. 39.8). 3’, 5’-cyclic AMP or cAMP is a major metabolic regulator. Cyclic GMP also behaves similarly. These are second messengers in mediating the action of several hormones.

iv. Deoxy ribonucleotides are used for synthesis of DNA and ribonucleotides for RNA. In pseudo-uridylic acid (found in tRNA) uridine is attached to ribose phosphate in a C-C bond instead of C-N bond in UMP (Fig. 39.9).

v. High energy compounds are listed in Table 19.2. Please note that active methionine, amino acid adenylates, active sulfate etc are higher energy compounds containing adenosine monophosphate.

Digestion of Nucleic Acids

The nucleic acids in the diet are hydrolyzed to a mixture of nucleotides by ribonuclease and deoxy ribonuclease present in pancreatic and intestinal secretions. Then nucleotidases liberate the phosphate from nucleotides. The resulting nucleosides are hydrolyzed by nucleosidases forming free bases and pentose sugars.

However, the dietary purines and pyrimidines are neither converted to nucleotides nor incorporated into nucleic acids. They are directly catabolized.

BIOSYNTHESIS OF PURINE NUCLEOTIDES

i. The purine nucleotides are synthesized by most of the tissues. However the major site is the liver. This pathway operates in the cytoplasm.
ii. The major pathway is denoted as **de novo synthesis**, because the purine ring is synthesized from different small components. Since the human being can synthesize the purine and pyrimidine bases de novo, they are said to be prototrophs.

iii. The contribution of different atoms from different sources for the formation of the purine ring is shown in the Figure 39.10.

iv. During de novo synthesis, **purine ring is built up on a ribose-5-phosphate molecule**. Hence nucleotides are the products of the de novo synthesis.

v. There are ten steps in the de novo synthesis pathway. The enzymes catalyzing these reactions are existing as a multienzyme complex in eukaryotic cells; this arrangement increases the efficiency of the pathway. The names of the enzymes catalyzing the purine synthesis steps are as follows (see Figs 39.12 and 39.13)

![Fig. 39.10. The assembly of purine ring is from various sources. THFA (FH₄) = tetra hydro folic acid](image)

The expansions of the abbreviated forms of the products are shown in Figures 39.12 and 39.13.

**Fig. 39.11. Phospho ribosyl pyrophosphate**

**Step 0 (Preparatory Step), PRPP synthesis**

i. Phospho ribosyl pyrophosphate (PRPP) is the donor of ribose-5-phosphate for de novo synthesis. The reaction is:

\[
\text{Ribose-5-phosphate} + \text{ATP} \rightarrow \text{ADP} + \text{Phospho ribosyl pyrophosphate (PRPP)}
\]

The structure of PRPP is shown in Figure 39.11.

ii. The purine ring is later on assembled on the ribose-5-phosphate.

iii. PRPP is also used for the synthesis of pyrimidine nucleotides, nucleotide co-enzymes and also for the salvage pathway. Hence the synthesis of PRPP is not considered as a step in the de novo synthesis of purine nucleotides; it is called a preliminary or preparatory step.

**Formation of AMP**

Steps 1 to 10 are summarized in Table 39.5. Flow diagrams of these steps are shown in Figures 39.12 and 39.13. The de novo synthesis of one molecule of purine nucleotide requires 6 ATP.

First step is the rate limiting enzyme. Step 4 is inhibited by **azaserine**, an anticancer drug. 6-mercaptopurine inhibits amination of IMP to AMP, and so it is an anticancer drug.

**Conversion of IMP to GMP**

The conversion of IMP to GMP involves two steps, first oxidation of IMP to xanthyl acid (xanthosine monophosphate) (XMP) by an NAD⁺ dependent dehydrogenase. Then an amido transferase transfers the NH₃ group from glutamine to XMP to form GMP. ATP is hydrolyzed to AMP level in this reaction (Fig. 39.14). Both AMP and GMP can be converted to their di- and tri- phosphates. Synthesis of one molecule of purine nucleotide requires 6 high energy phosphates.

**Salvage Pathway**

i. This pathway ensures the recycling of purines formed by degradation of nucleotides. Nucleosides and deoxy-nucleosides can also be salvaged.

ii. PRPP is the starting material in this pathway; it is also a substrate for de novo synthesis. Hence these two pathways are closely interrelated.
iii. The free purines are salvaged by two different enzymes; adenine phospho ribosyl transferase (APRTase) and hypoxanthine guanine phosphoribosyl transferase (HGPRTase).

iv. The pathway is of special importance in tissues like RBCs and brain where the de novo pathway is not operating. The salvage pathway economizes intracellular energy expenditure.

v. Absence of enzymes of salvage pathway produces specific clinical syndromes. Salvage pathway is summarized below:

\[
\text{APRTase} \\
\text{Adenine + PRPP} \rightarrow \text{AMP + PPi} \\
\text{HGPRTase} \\
\text{Guanine + PRPP} \rightarrow \text{GMP + PPi} \\
\text{HGPRTase} \\
\text{Hypoxanthine + PRPP} \rightarrow \text{IMP + PPi}
\]

**Regulation of Purine Synthesis**

i. The committed step in de novo synthesis is the reaction catalyzed by amido-transferase (step 1). It is inhibited by AMP and GMP.

ii. They act as allosteric modifiers. Binding of AMP and GMP on the enzyme converts monomeric active form to a dimeric inactive form.

iii. Since both AMP and GMP can bind to the same enzyme molecule at different sites, they act synergistically.

iv. Both AMP and GMP inhibit their own formation by feedback inhibition of adenylosuccinate synthetase and IMP dehydrogenase.

v. The formation of AMP from IMP requires GTP; similarly formation of GMP requires ATP. Hence both GTP and ATP are made available in sufficient quantities.

vi. The availability of PRPP is another important regulatory factor. The activity of PRPP synthetase is regulated by negative modifiers; purine and pyrimidine nucleotides.

**Analogues as Purine Synthesis Inhibitors**

They act as competitive inhibitors of the naturally occurring nucleotides that are used to synthesize DNA. When wrong bases are incorporated, the DNA becomes functionally inactive. Thereby cell division is arrested. So they are useful as anticancer drugs. A few examples are:

a. Mercaptopurine inhibits the conversion of IMP to GMP and AMP.

b. Folate antagonists (Methotrexate) would affect the reactions involving one carbon group transfers.
Degradation of Purine Nucleotides

The end product of purine nucleotide catabolism is uric acid (urate). The structure is shown in Figure 39.2. This degradation is taking place mainly in the liver. The steps are shown in Figure 39.15.

The xanthine oxidase is a metalloflavoprotein containing FAD, molybdenum and iron. As xanthine is oxidized to uric acid, the electrons are transferred first to molybdenum, then to FAD, and finally to molecular oxygen, when hydrogen peroxide (one of the reactive oxygen species) is produced.

Species difference

The end product of purine catabolism in human beings is uric acid. However, the total amount of nitrogen excreted as uric acid is very little, because human beings are ureotelic. The amino nitrogen is finally excreted as urea in mammals. The birds, amphibians and reptiles are uricotelic because they excrete uric acid as the major end product of purine as well as amino acid catabolism. The lower primates and some other mammals have the enzyme uricase which converts uric acid to allantoin and the final product excreted is allantoin which is more soluble.

Caffeine

Caffeine is the trimethyl derivative of xanthine. Coffee and tea contains caffeine. It inhibits phosphodiesterase, causes prolonged action of cyclic AMP and increases the activity of hormone sensitive lipase (Fig. 11.16). Caffeine enhances the effect of epinephrine on glycogenolysis.

URIC ACID

Strecker in 1857 showed the presence of uric acid in urine. In 1892, Sir Frederick Hopkins (Nobel prize, 1929) estimated uric acid. In 1895, Emil Fischer (Nobel prize, 1902) showed that uric acid is derived from purine nucleus.

Normal blood level of uric acid ranges from 2-5 mg/dl in females and 3-7 mg/dl in males. The daily excretion varies from 500-700 mg.
content is more in non-vegetarian diet. Uric acid is sparingly soluble in water.

**Disorders of Purine Metabolism**
The most common abnormality is an elevation of uric acid level in blood, referred to as hyperuricemia. It is defined as serum uric acid concentration exceeding 7 mg/dl in male and 6 mg/dl in female. It may or may not be associated with increased excretion of uric acid in urine, which condition is called uricosuria. The manifestations are due to the low solubility of uric acid in water.

**GOUT**

i. It is due to accumulation of urate crystals in the synovial fluid resulting in inflammation leading to acute arthritis.

ii. At 30°C, the solubility of uric acid is lowered to 4.5 mg/dl. Therefore uric acid is deposited in cooler areas of the body to cause tophi. Thus tophi are seen in distal joints of foot.

iii. Increased excretion of uric acid may cause deposition of uric acid crystals in the urinary tract leading to calculi or stone formation with renal damage. Gout may be either primary or secondary.

1. **Primary Gout**

   About 10% of cases of primary gout are idiopathic. Primary gout may show a familial incidence. Incidence of primary gout is about 1:500 in total population. Causes of primary gout are:

   1-A. 5-phosphoribosyl amido transferase
   
   The abnormal enzyme is active, but not sensitive to feedback regulation by the inhibitory nucleotides. This would lead to overproduction of purine nucleotides.

   1-B. Abnormal PRPP synthetase
   
   The enzyme is not subject to normal allosteric control mechanisms and this could lead to increased production of PRPP. The condition is X-linked and recessive.

   1-C. Deficiency of enzymes of salvage pathway
   
   This would result in increased availability of PRPP and decreased purines; so feedback inhibition is lost.

   1-D. Glucose-6-phosphatase deficiency
   
   This condition is known as von Gierke’s disease (glycogen storage disease, type I, see Chapter 9). When this enzyme is deficient, glucose-6-phosphate cannot be converted to glucose. So more glucose is channelled into the pentose-phosphate shunt pathway, resulting in increased availability of ribose-5-phosphate. This would lead to increased formation of PRPP.

   1-E. Glutathione reductase variant
   
   This enzyme depends on NADPH generated by pentose phosphate pathway. The abnormality in enzyme leads to increased production of ribose-5-phosphate and thereby increased level of PRPP. Dysregulation of the rate limiting step of purine nucleotide synthesis leads to increased synthesis and degradation of uric acid.

2. **Secondary Hyperuricemia**

   2-A. Increased production of uric acid
   
   It may be due to enhanced turnover rate of nucleic acids as seen in
Chapter 39: Nucleotides: Chemistry and Metabolism

2-B. Reduced excretion rate

i. Renal failure.

ii. Treatment with thiazide diuretics which inhibit tubular secretion of uric acid.

iii. Lactic acidosis and keto-acidosis due to interference with tubular secretion.

3. Clinical Findings of Gout

Galen has described the classical image of the gouty subjects as the red faced, good living, hard drinking, country squire. Many geniuses, including Isaac Newton, Gibbon and Johnson were suffering from gout.

Gouty attacks may be precipitated by high purine diet and increased intake of alcohol. Often the patients have a few drinks, go to sleep symptomless, but are awakened during the early hours of morning by excruciating joint pains. Alcohol leads to accumulation of lactic acid.

The typical gouty arthritis affects the first metatarsophalangeal joint (big toe), but other joints may also be affected. The joints are extremely painful. Synovial fluid will show birefringent urate crystals.

In chronic cases, uric acid may get deposited around joints causing swelling (tophi) composed of sodium urate. The total urate pool (normal 1200 mg) is increased to 3000 mg in gout patients without tophi. It may be as high as 30,000 mg in patients with tophi.

In chronic gout, the deposition of urate crystals in renal medulla occurs which progresses to urolithiasis and renal damage.

Lesch-Nyhan Syndrome

It is an X-linked inherited disorder of purine metabolism. Incidence is 1:10,000 males. There is deficiency of HGPRTase. So, the rate of salvage pathway is decreased resulting in accumulation of PRPP and decreased level of inhibitory purine nucleotides. The disease is characterized by self mutilation, mental retardation, excessive uric acid and nephro-lithiasis. Gout develops in later life. The neurological manifestations suggest that the brain is dependent on the salvage pathway for the requirements of IMP and GMP.

Hypouricemia

Adenosine Deaminase (ADA) Deficiency

It is associated with severe immunodeficiency where both T and B cells are deficient. It is an inherited autosomal recessive disease. ADA deficiency leads to accumulation of adenosine

Treatment Policies in Gout

i. Reduce dietary purine intake and restrict alcohol.

ii. Increase renal excretion of urate by uricosuric drugs, which decrease the reabsorption of uric acid from kidney tubules, e.g. probenecid.

iii. Reduce urate production by allopurinol, an analogue of hypoxanthine (Fig. 39.16). Allopurinol is a competitive inhibitor of xanthine oxidase thereby decreasing the formation of uric acid. Xanthine and hypoxanthine are more soluble and so are excreted more easily. Xanthine oxidase converts allopurinol to allooxanthine. It is a more effective inhibitor of xanthine oxidase. This is a good example of ‘suicide inhibition’ (Chapter 5). Allopurinol was synthetised by Elion and Hitchings independently (Nobel prize, 1988).

iv. Colchicine, an anti-inflammatory agent is very useful to arrest the arthritis in gout.

Fig. 39.16. Allopurinol inhibits xanthine oxidase; an example of competitive inhibition

Fig. 39.17. Sources of C and N atoms of pyrimidine
and dATP; this would inhibit further production of precursors for DNA synthesis especially dCTP. Lymphocytes usually contain high quantity of ADA. Therefore ADA deficiency is mainly manifested as reduced lymphocytes. This leads to impaired cellular and humoral immunity. Hypouricemia is due to defective breakdown of purine nucleotides. Antibiotics and periodic injections of immunoglobulin will be life saving. Weekly intramuscular injections of bovine ADA were found to be beneficial. Bone marrow stem cells will increase both T and B cells in the patients. The first successful gene replacement therapy has been tried in ADA deficiency (Chapter 43).

**Xanthine Oxidase Deficiency**
It is a genetic defect. Characteristic features are hypouricemia, increased excretion of hypoxanthine and xanthine and liver damage.

**DE NOVO SYNTHESIS OF PYRIMIDINE**
The pyrimidine ring (unlike the purine) is synthesized as free pyrimidine and then it is incorporated into the nucleotide. The origin of atoms of pyrimidine nucleus is indicated in Figure 39.17.

**Step 1: Carbamoyl Phosphate Synthesis**
The reaction occurs in cytoplasm (in urea synthesis, the reaction is in mitochondria). The nitrogen of glutamine and bicarbonate react to form carbamoyl phosphate (step 1, Fig. 39.18). The enzyme is carbamoyl phosphate synthetase II (CPS II). (The differences between CPS-I and CPS-II are described in Table 14.2).

**Step 2: Rate Limiting Step**
Carbamoyl phosphate and aspartate combine to form carbamoyl aspartate (step 2, Fig. 39.18). The enzyme is aspartyl transcarbamoylase (ATC), which is allosterically regulated. The atoms C2 and N3 are derived from carbamoyl phosphate and the rest are from aspartate.

**Step 3: Formation of Pyrimidine Ring**
The 3rd nitrogen and 4th carbon are joined by a covalent bond and carbamoyl aspartate is cyclised. Dihydro orotic acid is produced. The enzyme is dihydro orotase (DHOase) (step 3, Fig. 39.18).

**Step 4: Oxidation**
Hydrogen atoms are removed from C5 and C6 positions, so that orotic acid is produced (step 4, Fig. 39.18). Enzyme is dihydro orotate dehydrogenase (DHODH). It requires NAD as co-enzyme.

**Step 5: Formation of OMP**
Ribose-5-phosphate is added to orotic acid, so as to produce orotidylic acid or orotidine monophosphate (OMP). PRPP is the donor of ribose-5-P. The enzyme is orotate phosphoribosyl transferase (OPRTase) (step 5, Fig. 39.18).

**Step 6: Decarboxylation**
The C7 of OMP is removed as carbon dioxide, so that uridine monophosphate (UMP) is produced (step 6, Fig. 39.18). This
is the first purine that is synthesized. The enzyme is OMP-decarboxylase (OMPDC). 6-aza-uridine inhibits this step, and so used as an anticancer drug.

Step 7, Synthesis of Triphosphates
UMP is phosphorylated to form UDP (uridine diphosphate) with the help of ATP (step 7, Fig. 39.18). The enzyme is nucleoside monophosphate kinase (UMP kinase). Next, the UDP is phosphorylated to UTP (uridine triphosphate) with the help of ATP (step 8, Fig. 39.18). The enzyme is nucleoside diphosphate kinase.

Step 8, Formation of CTP
UTP is converted to CTP by adding an amino group from glutamine catalysed by CTP synthetase. It needs ATP (step 9, Fig. 39.18).

Regulation of Pyrimidine Synthesis
i. In eukaryotes the first 3 enzymes, viz, CPS II, ATC and DHOase are present as a multi-enzyme complex and referred to as ‘CAD’, taking the first letters of the 3 enzymes.

ii. The last 2 enzymes, OPRTase and OMP decarboxylase are also present as a single functional complex. Because of this clustering of enzymes, the synthesis is well co-ordinated. Both complexes are cytosolic.

iii. The remaining enzyme, dihydro orotate dehydrogenase (step 4) is mitochondrial.

iv. The major regulatory step in prokaryotes is the reaction catalysed by aspartate trans-carbamoylase (ATC) which is allosterically inhibited by CTP.

v. In mammalian cells the regulation occurs at the level of CPS II (enzyme 1) which is inhibited by UTP are activated by PRPP. Aspartate trans carbamoylase (enzyme 2) is inhibited by CTP, and activated by ATP.

vi. Further, OMP decarboxylase is inhibited by UMP. The requirement of ATP for CTP formation and the stimulatory effect of GTP on CTP synthetase ensure a balanced synthesis of purine and pyrimidine nucleotides.

vii. Pyrimidines can also be salvaged like the purines, using PRPP and phosphoribosyl transferase and nucleoside phosphorylase.

viii. Both gene expression and enzyme activity are regulated. The first 3 and last 2 enzymes are regulated by repression / depression.

Disorders of Pyrimidine Metabolism
Orotic Aciduria
i. The condition results from absence of either or both of the enzymes, OPRTase and OMP decarboxylase. The reaction needs 1 carbon units, and folic acid. DHF = dihydro folic acid. THF = tetrahydro folic acid.

Methotrexate inhibits the enzyme DHF-reductase. So dTMP synthesis is inhibited, in turn DNA synthesis is inhibited.
468  ▪  Textbook of Biochemistry; Section E: Molecular Biology

Decarboxylase. It is an autosomal recessive disease.

ii. There is retarded growth and megaloblastic anemia. The rapidly growing cells are more affected and hence the anemia. Crystals are excreted in urine which may cause urinary tract obstruction. Due to lack of feedback inhibition orotic acid production is excessive.

iii. The condition can be successfully treated by feeding cytidine or uridine. They may be converted to UTP which can act as feedback inhibitor.

iv. Orotic aciduria may also occur in ornithine transcarbamoylase deficiency (urea cycle enzyme) as carbamoyl phosphate accumulates due to defective conversion to citrulline.

v. Allopurinol competes with orotic acid for the enzyme orotate phosphoribosyl transferase (enzyme no.5 in Fig. 39.18.), leading to orotic aciduria and orotidinuria.

**Deoxy Ribonucleotide Formation**

Deoxy ribonucleotides (both purines and pyrimidine series) are formed by the reduction at the 2' carbon of the corresponding nucleoside diphosphates (NDP to dNDP). The enzyme is ribonucleotide reductase complex, which contains non-heme iron. It requires NADPH, Thioredoxin and thioredoxin reductase (Fig. 39.19). Thus, UDP is first converted to dUDP and then to dUTP.

**Combined Regulation of Purine and Pyrimidine Synthesis**

Purine and pyrimidines are synthesized in equimolecular quantities. This suggests co-ordinated control of their biosynthesis. PRPP is the precursor of both purines and pyrimidines; the PRPP synthase is inhibited by both purine and pyrimidine nucleotides. Both series of reactions are closely regulated by allosteric effectors. Binding of a specific NTP to the substrate-specificity site will have positive effect on the reduction of other NTPs (Table 39.6). Since ATP is required for the reduction of both CDP and UDP, the purine to pyrimidine balance is always maintained.

**Synthesis of Deoxothyminucleotides**

The thymine nucleotide is formed by thymidylate synthase by methylation of dUMP. The methyl group is donated by N5,N10-methylene-THFA. Later, THFA is regenerated by dihydro folate reductase, using NADPH as the reductant (Fig. 39.20). Methotrexate inhibits the enzyme DHF-reductase. So dTMP synthesis is inhibited, in turn DNA synthesis is inhibited.

**Anticancer Agents Acting on Pyrimidines**

Methotrexate inhibits dihydrofolate reductase and thereby reduces the regeneration of THFA; it is a powerful anticancer agent (Fig. 39.20).

5-fluoro-uracil, 5-iodo uracil, 3-deoxy uridine, 6-aza uridine, 6-aza cytidine and 5-iodo-2-deoxy-uridine are anticancer drugs, which competitively inhibit thymidylate synthase. Cytosine arabinoside where ribose is replaced by arabinose is another anticancer agent.

**Degradation of Pyrimidine Nucleotides**

Uracil and thymine are degraded by analogous reactions. The phosphate is removed from nucleotide to form corresponding nucleoside. In the next step, free base is released. The ring is opened. Finally, beta-amino isobutyric acid is excreted in urine. This is the end product of pyrimidines. Other products are carbon dioxide and ammonia (Fig. 39.21). Pseudouridine is not metabolized further, and is excreted as such in urine.

Deoxyribo Nucleic Acid (DNA): Structure and Replication

Thomas Morgan (1866-1945), the founder of modern genetics, showed that chromosomes contain genes in a sequential manner in Drosophila (Nobel prize, 1933). In 1931, Barbara McClintock showed the rearrangement of genes or mobile genes in chromosomes in corn (Nobel prize, 1983). George Beadle, working with mutant strains of Neurospora suggested "one enzyme one gene" hypothesis in 1941 (Nobel prize, 1958). Avery in 1944 demonstrated that DNA is the genetic material. In 1952, Hershey (Nobel Prize 1946) showed that only DNA of virus and not the proteins will enter into the host before infection. Edwin Chargaff elicited the base pairing rule of DNA in 1950. X-ray crystallographic studies on DNA by Maurice Wilkins (Nobel prize, 1962) showed the details of structure of DNA. Rosalind Franklin worked out the helical structure of DNA. (She died of ovarian cancer at the age of 37, probably due to irradiation during her work on X-ray crystallography). Based on these data, James Watson and Francis Crick in 1953 deduced the double helical structure of DNA (Nobel prize, 1962).

**STRUCTURE OF DNA**

Deoxyribonucleic acid (DNA) is composed of four deoxy ribonucleotides, i.e. deoxyadenylate (A), deoxyguanylate (G), deoxycytidylate (C), and thymidylate (T).

These units are combined through 3' to 5' phospho diester bonds to polymerise into a long chain. The nucleotide is formed by a combination of base + sugar + phosphoric acid. The 3’-hydroxyl of one sugar is combined to the 5’-hydroxyl of another sugar through a phosphate group (Fig. 40.1). In this particular example, the thymidine is attached to cytidine and then cytidine to adenosine through phospho-diester linkages (Fig. 40.1).

In the DNA, the base sequence is of paramount importance. The genetic information is coded in the
specific sequence of bases; if the base is altered, the information is also altered.

The deoxyribose and phosphodiester linkages are the same in all the repeating nucleotides. Therefore, the message will be conveyed, even if the base sequences alone are mentioned as shown:

5'P--Thymine--Cytosine-Adenine-3'OH  
Or, 5'------T--C--A---3'

This would convey all the salient features of the polynucleotide shown in Figure 40.1.

**Polarity of DNA molecule**

In the case of DNA, the base sequence is always written from the 5' end to the 3' end. This is called the polarity of the DNA chain.

**Watson-Crick Model of DNA Structure**

The salient features of Watson-Crick model of DNA are given below (Figs 40.2 and 40.3):

1. **Right handed double helix**

DNA consists of two polydeoxy ribonucleotide chains twisted around one another in a right handed double helix similar to a spiral staircase. The sugar and phosphate groups comprise the handrail and the bases jutting inside represent the steps of the staircase. The bases are located perpendicular to the helix axis, whereas the sugars are nearly at right angles to the axis.

2. **The base pairing rule**

Always the two strands are complementary to each other. So, the adenine of one strand will pair with thymine of the opposite strand, while guanine will pair with cytosine. The base pairing (A with T; G with C) is called Chargaff’s rule, which states that the number of purines is equal to the number of pyrimidines.

3. **Hydrogen bonding**

The DNA strands are held together mainly by hydrogen bonds between the purine and pyrimidine bases. There are two hydrogen bonds between A and T while there are three hydrogen bonds between C and G. The GC bond is therefore stronger than the AT bond.

4. **Antiparallel**

The two strands in a DNA molecule run antiparallel, which means that one strand runs in the 5' to 3' direction, while the other is in the 3' to 5' direction. (Fig. 40.2). This is similar to a road divided into two, each half carrying traffic in the opposite direction.
5. Other features

In the DNA, each strand acts as a template for the synthesis of the opposite strand during replication process. The spiral has a pitch of 3.4 nanometers per turn. Within a single turn, 10 base pairs are seen. Thus, adjacent bases are separated by 0.34 nm. The diameter or width of the helix is 1.9 to 2.0 nanometers. A major groove (1.2 nm) and a minor groove (0.6 nm) wind along the molecule, parallel to the phospho-diester backbone. In these grooves, proteins interact with the exposed bases.

Denaturation of DNA strands

The double stranded DNA may be denatured and separated by heat. This is called as melting of DNA. Tm or melting temperature is the temperature when half of the helical structure is denatured. At lower temperature, the melted strands are re-associated; this is called annealing.

Higher Organization of DNA

In higher organisms, DNA is organized inside the nucleus. Double stranded DNA is first wound over histones; this is called nucleosomes (Fig. 40.4). Chromatin is a loose term employed for a long stretch of DNA in association with histones. Chromatin is then further and further condensed to form chromosomes (Fig. 40.5). Similarly, the DNA molecule is folded and compressed to 10,000 fold to generate chromosomes (Fig. 40.5).

Histones

They are proteins containing unusually higher concentration of basic amino acids. There are 5 classes; H1, H2A, H2B, H3 and H4. The H1 histone is loosely attached to the DNA (Fig. 40.4). Others are called core histones because they form the nucleosome (Fig. 40.4). Amino terminal one-third region of H2A and H2B are lysine rich. H3 and H4 are arginine rich histones. Histone synthesis stops when DNA synthesis ceases. Histones synthesized in the cytoplasm migrate to the nucleus. Histones are modified by acetylation, methylation, ADP-ribosylation and phosphorylation. Acetylation and methylation of lysine residues are the most common modifications. Acetylation of histones leads to activation of transcription, whereas de-acetylation causes depression of transcription. Phosphorylation is associated with condensation of chromosomes. ADP-ribosylation is associated with DNA repair. Methylation generally occurs when the gene is repressed. Sometimes histones are fixed to small ubiquitin related modifier (abbreviated as Sumo), and the process is called sumoylation. Sumoylation of histones is seen during repression of transcription.

Apart from histones, there are many other special proteins which will interact at specific regions of DNA. The protein–DNA interactions are mainly mediated by 3 motifs – Helix-turn-helix, zinc finger and leucine zipper motifs. Only small regions of the protein make direct contact with the DNA; the rest of the proteins are involved in other activities, like dimerisation, ligand-binding, interaction with co-activators and corepressors etc. DNA binding and trans-activation domains of most regulatory proteins are separate and non-interactive.

Nucleosomes

The double stranded DNA wraps twice around a histone octamer formed by H2A, H2B, H3 and H4 (Fig. 40.4). This super-twisted helix forms a spherical particle of 10 nm diameter; called nucleosome. The function of the nucleosome is to condense DNA; this arrangement also stabilises DNA.

Further Condensation of DNA

The supercoiled DNA with histones (nucleosomes) will have a diameter of about 10 nm. A group of such nucleosomes form
the "DNA fibrils". About 6 such fibrils are further supercoiled to form 30 nm diameter chromatin fibers or chromatin threads. By this time, the DNA is folded to about 100 times. Histones stabilise these fibers. In interphase chromosomes, chromatin fibers condense to 100,000 bp loops, anchored in some supporting matrix (nuclear matrix) (Fig. 40.5).

**DNA is a Very Big Molecule**

Human diploid genome consists of about $7 \times 10^9$ base pairs and bases are at a distance of 0.34 nm. So when placed end to end it will be about two meters long! If one nucleotide is added per second, it will take 250 years to synthesize the whole DNA of a human cell. The length of a DNA molecule is compressed to 8,000 to 10,000 fold to generate the chromosomes (Fig. 40.5).

**Chromosomes**

These fibers are further supercoiled and condensed to form chromosomes during the M phase of cell cycle. The packaging of nucleoproteins within chromosome is specific, as shown by characteristic patterns (banding) observed by Giemsa's staining (Fig. 40.6). During metaphase, the DNA can be seen under a microscope, as superpacked chromosomes, where identical sister chromatids are connected at the centromere. Depending on the length of the chromosome and the position of the centromere, the chromosomes are numbered. In humans, there are 23 pairs of chromosomes (Fig. 40.7). The position of centromere is the characteristic mark for specific chromosome. The centromere is AT rich region, and has repeated DNA sequences of about one million base pairs in mammals. This region also shows a lot of specific centromere binding proteins. This region is called kinetochore, which provides the anchor for the mitotic spindle.

**Activity of Chromatin**

Transcriptionally active regions of chromatin are sensitive to digestion by deoxy ribonuclease-1 (DNase-1). These are 100,000 bp long. Certain portions of the active regions contain hypersensitive sites to DNase, these are 100-200 nucleotides long. These regions are supposed to be the site where transcription factor proteins are assembled, and where transcription is initiated. Active regions stain less densely and are called euchromatin. Euchromatin fills up the majority of the nucleus. Transcriptionally inactive chromatin is densely packed and is called heterochromatin.

**Inactivation of DNA During Differentiation**

All human cells are derived from a single cell, the zygote. Therefore, all cells contain the same genetic information. But, a cell from the gastrointestinal epithelium is different from a cell of central nervous system, by structure and function. How such a differentiation is made possible? In a cell, about 90% DNA are permanently inactive. Histones and specific proteins help in this inactivation process and consequent differentiation.

**Introns, Exons, Cistron**

As the evolution proceeds, DNA content has also increased (Table 40.1).

The segments of the gene coding for proteins are called exons (expressed regions). They are interspaced in the DNA with stretches of silent areas, called introns (intervening areas). The primary mRNA transcripts contain intron sequences; which
are later removed to produce mature mRNA. Introns are not translated. Actual function of introns is not clear. It may serve to separate exons so that genetic recombination can occur more easily and efficiently.

A Cistron is the unit of genetic expression. It is the biochemical counterpart of a "gene" of classical genetics. One cistron will code for one polypeptide chain. If a protein contains 4 subunits, these are produced under the direction of 4 cistrons ("one cistron—one polypeptide" concept).

**Repeat Sequences of DNA**

Only about 1-2% of the human DNA contain genes; the rest are silent areas. About 1% of DNA is present inside mitochondria. There are only about 25,000 to 30,000 protein-coding regions in the human DNA. Thus, most of the DNA is made of noncoding sequences. About 90% of DNA is introns. About 50% of DNA is unique or nonrepetitive. About 30% of the genome consists of repetitive sequences; they contain 5-500 base pairs repeated many times. Some sequences are repeated many times. These regions are clustered mainly in centromeres and telomeres; but are seen randomly in other regions also. Repetitive sequences include highly repetitive sequences, moderately repetitive sequences; long dispersed repeat sequences (LINEs) or short interspersed repeat sequences (SINEs). Long interspersed repeat sequences (LINE) are 6-7 kbp length and are repeated about 50,000 times. The short interspersed repeat sequences (SINE) are 100-300 bp in length, but are repeated 100,000 times. One such sequence, the Alu family, is repeated about 500,000 times, and accounts for about 5% of total human DNA. These interspersed repeat sequences are mobile elements, and they can jump from one region to another region of the genome. They appear to be retroposons, i.e. they can move from one location to another (transposition) through an RNA intermediate by the action of reverse transcriptase. Microsatellite repeat sequences are AC repeats on one strand and TG on the other strand; such repeats are 100,000 in the genome. Trinucleotide sequence repeats are associated with diseases. Thus, CGG repeat sequence is seen in fragile X syndrome. Similarly CAG repeats are seen in Huntingon's chorea, CTG in myotonic dystrophy, CAG in spinobulbar muscular atrophy.

**REPLICATION OF DNA**

During cell division, each daughter cell gets an exact copy of the genetic information of the mother cell. This process of copying the DNA is known as DNA replication.

In the daughter cell, one strand is derived from the mother cell; while the other strand is newly
synthesized. This is called semiconservative type of DNA replication. Each strand serves as a template or mould, over which a new complementary strand is synthesized (Fig. 40.9).

Meselson-Stahl Experiment (1958)
Bacteria were grown in a medium containing the heavy isotope of nitrogen $^{15}$N, when all the DNA was labelled with heavy nitrogen. These cells were allowed to divide in a medium containing normal nitrogen, $^{14}$N. In the first generation, all DNA molecules were half labelled. In the second generation half labelled and completely unlabelled molecules were present in equal numbers. From this experiment (Fig. 40.8), it was proved that DNA replication is semiconservative in vivo.

The base pairing rule is always maintained. The new strand is joined to the old strand by hydrogen bonds between base pairs (A with T and G with C) (Figs 40.3 and 40.10). The replication is summarised in Figure 40.11. The whole process may be studied under the following steps:

1. Origin of Replication (ori)
The DNA replication starts with the recognition of the site of origin of replication. This is done by a complex. Many origins of replication, called autonomous replicating sequences (ARS) have been identified in mammals. The origin of replication on the DNA strand in bacteria is termed as ori. Corresponding areas in higher organisms are called replicators, which contain certain base sequences called the origin replication element (ORE). This area is recognized by specific proteins collectively called the origin recognition complex (ORC).

2. Unwinding of DNA
DNA helicase unwinds the DNA.
   i. Topo-isomerases, Gyrases and Helicases, all of them unwind the DNA. Relief of supercoil is done by topo-

3. Components of DNA Replisome
The complex of enzyme proteins and other factors required for DNA replication is called Replisome. DNA replication needs the participation of more than 20 enzymes and proteins, collectively called DNA replicase system or replisomes. The important components are:
   i. The protein A or DnaA binds at specific sites of origin, and opens the duplex.
   ii. Type II acts by introducing double stranded breaks, rotation occurs and the breaks are resealed.
   iii. Gyrase is a bacterial type II topo-isomerase which acts on closed circular DNA (bacteria have circular DNA).
   iv. Helicase separates the strands of DNA, without a cut, but using energy from hydrolysis of ATP.

4. Replication Bubble
Each replication fork contains (Fig. 40.12) a. DNA helicase which unwinds a short region of DNA helix.
   b. Primase that initiates synthesis of a short RNA segment (see below).
c. DNA polymerase enzyme that synthesis the new strand of DNA (see below)

d. DNA is prevented from recoiling by SSBs.

5. DNA Polymerase (DNAP)

This enzyme synthesises a new complementary strand of DNA, by incorporating dNMP sequentially in 5' to 3' direction, making use of single stranded DNA as template.

5-A. Bacterial DNA polymerases

In bacteria there are 5 polymerases. Arthur Kornberg (Nobel prize, 1959) isolated the DNA polymerase I (Kornberg's enzyme) from Escherichia coli. It is a repair enzyme. It has both 3' to 5' and 5' to 3' exonuclease activities. When 5' to 3' exonuclease domain is removed, the remaining fragment retains the polymerisation and proof reading activities; it is then called Klenow fragment. It is widely used in recombinant DNA technology. Bacterial DNA polymerase III is the main replication enzyme in bacteria. It has beta, gamma, delta, delta dash units. Bacterial polymerases type IV and V were identified in 1999.

5-B. Mammalian DNA Polymerases (DNAP)

In mammalian cells (eukaryotic), there are 5 DNAPs, named as α, β, γ, δ, ε. The enzyme polymerase alpha is the major enzyme responsible for chromosome replication. This enzyme polymerises about 100 nucleotides per seconds (Bacterial enzyme speed is about 10 times more). Mammalian alpha DNAP has 4 subunits, one of which has primase activity. Mammalian beta DNAP is a repair enzyme. DNAP gamma is concerned with mitochondrial DNA synthesis. Delta enzyme is used for both leading and lagging strand synthesis. Epsilon is used for leading strand synthesis.
6. RNA Primer is Required for DNA Synthesis
An RNA primer, about 100-200 nucleotides long, is synthesized by the RNA primase. Then the RNA primer is removed by DNAP, using exonuclease activity and is replaced with deoxyribo nucleotides by DNAP (Fig. 40.13).

7. Elongation of DNA Strand
Under the influence of DNA polymerase, the 3' hydroxyl group of the end nucleotide combines with the 5' phosphate group of the new deoxynucleotide. The pyrophosphate is released from the deoxynucleoside triphosphate (Figs 40.10 and 40.11). This newly added nucleotide would now polymerise with another one, forming the next phosphodiester bond. If "A" is present on the template, "T" enters in that place in the newly synthesized DNA strand. The base pairing rule is always observed. The DNA polymerase carries out the sequential addition of each nucleotide complementary to the one in the template strand.

Polymerisation: Polymerisation of the new strand of DNA is taking place from 5' to 3' direction. This means that the template is read in the 3' to 5' direction (Figs 40.10 and 40.11). That is, the 3rd hydroxyl of the last deoxynucleotide is joined with the 5th phosphate of the newly entering nucleotide. Thus, the 3' end of the last nucleotide is free. This would mean that the template is read by the enzyme in the 3' to 5' direction.

Thus two double stranded molecules are produced. One molecule goes to one daughter nucleus, and the other to the second daughter nucleus. But each daughter cell gets only one strand of the parent DNA molecule. Old DNA strand is not degraded, but is conserved in the daughter cell, hence this is semiconservative synthesis (see Fig. 40.9).

8. Discontinuous Synthesis and Okazaki Pieces
i. DNA synthesis is always in the 5' to 3' direction in both strands. The strand which is discontinuously synthesized is referred to as the "lagging strand" otherwise called "retrograde strand" and the one continuously polymerised as the "leading strand" (Fig. 40.14). Replication of DNA is taking place on both strands simultaneously; but it is in pieces of about 100 to 250 nucleotides in length. This "discontinuous DNA synthesis" produces replication forks or replication bubbles (Fig. 40.12). Both strands are simultaneously replicated.

ii. The small DNA molecules attached to its own primer RNA are called Okazaki fragments. Several Okazaki pieces are produced. The synthesis along the lagging strand is in 5' to 3' direction. As it moves, the primase synthesises short RNA primer, to which deoxyribo nucleotides are added by DNA polymerase. (DNAP-alpha synthesises short pieces, which are extended by DNAP-delta. This delta enzyme has a role in the synthesis of both leading and lagging strands). DNAP-alpha has primase activity.

iii. DNA synthesis continues until the primer and previously added Okazaki fragment is encountered. Then the RNA primer is removed by DNAP, using exonuclease activity and is replaced with deoxyribo nucleotides by DNAP. The remaining nick is sealed by the DNA ligase.

9. Condensation into Chromatin Structure
Newly synthesized DNA is rapidly arranged into nucleosomes. This is facilitated by histone chaperone proteins and chromatin remodelling complexes. A summary of DNA replication is given in Box 40.1.
10. Modification after Replication

DNA methylation at C5 of cytosine catalysed by DNA methyl transferase is commonly associated with gene silencing and contributes to the X-chromosomal inactivation, genomic imprinting (selective silencing of maternal or paternal alleles). Transcriptional regulation of tissue specific genes during cellular differentiation also results from DNA methylation. Methylation occurs in CG rich areas in the promoter region. The changes in gene expression are inherited, but during the passage from one generation to another, the imprints may be erased and rewritten. Epigenetic information which modifies the genetic information are said to be the writings with nature’s pencil, that can be erased and rewritten.

The degree of methylation in normal cells and cancer cells are different. One of the effects of ROS (reactive oxygen species, free radicals) is through hypermethylation. Aberrant methylation is also observed in cellular senescence and may affect age-related diseases, such as type 2 diabetes mellitus.

Cell cycle

In G1 (gap 1) phase, the cell prepares for DNA synthesis. DNA synthesis occurs during the S (synthesis) phase of the cell cycle (Fig. 40.15). During the S phase, DNA is completely replicated, but only once. Cell prepares for mitosis in G2 (gap 2) phase, when proteins necessary for daughter cells are synthesized. Then the cell enters into the M (mitotic) phase, when chromosomes are visible under microscope. The whole cycle lasts about 24 hours; out of which M phase is only 1-2 hours. Those cells which are not in division are said to be in G0 phase or resting phase. Cell cycle, cyclins, CDKs, Rb protein etc are further described in Chapter 42.

DNA REPAIR MECHANISMS

1. General Repair

i. The replication process should be carried out with high fidelity, otherwise the information is altered. Hence there should be a foolproof mechanism to correct the mistakes. There are different types of DNA repair mechanisms; all of them follow the general mechanism outlined above, but details may vary. A summary of the DNA repair is given in Table 40.2.

ii. While printing a page, the typesetter sets the types; an impression is taken, proof reading is done to correct mistakes if any, and then the final printing is done. A similar follow-up mechanism operates after DNA synthesis.

iii. Various physical and chemical agents produce base alterations; these are to be appropriately corrected immediately. Deregulation of epigenome has been recognized as a fundamental mechanism of carcinogenesis. Hypermethylation of CG islands have been observed to silence oncosuppressor genes. Changes in histone modification, namely acetylation and methylation are seen in cancer cells compared to normal cells. Inhibition of epigenetic regulators like DNA methyl transferase (DMT) and histone decaetylase (HDAC) are being looked upon as therapeutic targets in cancer chemotherapy.

</tbody>
</table>
2. Exonucleolytic proof reading
The DNA polymerase has 3' to 5' exonuclease activity. Hence any mispaired nucleotide added is immediately removed (Fig. 40.16).

Nucleotide Excision Repair (NER)
NER is an important mechanism by which the cell can prevent unwanted mutations by removing the vast majority of UV-induced DNA damage (mostly in the form of thymine dimers). There are 9 major proteins involved in NER in Mammalian cells and their names come from the diseases associated with the deficiencies in those proteins. XPA, XPB, XPC, XPD, XPE, XPF and XPG; these names are derived from xeroderma pigmentosum and CSA and CSB are enzymes deficient in Cockayne syndrome. NER takes place along with the replication process (proof reading). The original template DNA contains methylated residues (N6-methyl adenine and 5-methyl cytosine). The newly synthesized strand will not have methylated bases. So enzymes can recognise the original (correct) DNA strand. The mismatched base is identified and removed along with a few bases around that area. The wrong base is removed by the endonuclease activity of the XPG. It removes 24-32 nucleotides around the wrong base. As the endonuclease cleaves at two points, the enzyme is sometimes also called excinuclease. A small segment of DNA with correct base sequence is then synthesized by DNA polymerase beta. Then the gap or nick is sealed by DNA ligase. The ligase requires energy input for its activity (Fig. 40.17).

Strand Directed Mismatch Repair
See Figure 40.18. Specific proteins scan the newly synthesized DNA strand (new strand is identified by not being methylated). The mismatched area is identified, a loop is made. In E.coli, this recognition and looping is done by three proteins, MutS,
MutC and MutH. Then that segment is removed. Finally correct segment is synthesized by the help of DNA polymerase, SSBs, and ligase.

**Base Excision Repair**
Depurination of DNA is a spontaneous process, which occurs at a rate of 10,000 per cell per day. Thus cytosine, adenine and guanine bases spontaneously form uracil, hypoxanthine and xanthine respectively. These are not normal constituents of DNA. Specific N-glycosylases can remove these abnormal bases. The sugar has no base. Apurinic endonucleases excise this abasic sugar. Proper base is then added by a repair DNAP and ligase.

**Mutations**
Even after proof reading some mistakes may be retained in the print. Similarly a few defects may remain in the DNA. These are called mutations. Mutations are due to a change in the base sequence of DNA. These may result from faulty replication or repair of DNA. Mutation rate is about 6 nucleotide changes per year in the germ cell line cells of an individual. Moreover, out of every $10^6$ cell divisions, one somatic mutation is taking place. Mutations and mutagens are further explained in Chapter 42.

**Diseases Associated with DNA Repair**
1. **Xeroderma Pigmentosum (XP)**
   It is derived from the Greek terms xeres = dry and derma = skin. It is an autosomal recessive condition. Defect lies in the NER (nucleotide excision repair) mechanism. There are seven XP genes (A to G) necessary for NER mechanism in humans. Mutation in any one of them may lead to the condition XP. UV light (sun light) causes formation of thymine dimers, where covalent bonds are formed between adjacent thymine residues. Since repair mechanism is not operating, these mutations are accumulated, leading to cancer. There is sensitivity to ultraviolet rays; sunlight causes blisters on the skin. Avoiding sunlight and using sunscreen ointment will be beneficial. Patients with XP have a 1000-fold greater chance of developing skin cancer than do normal persons. Death usually occurs in the second decade of life due to squamous cell carcinoma of skin. Prenatal diagnosis of XP is possible.

2. **Ataxia Telangiectasia (AT)**
   It is a common autosomal recessive disease. Sensitivity to UV, cerebellar ataxia, telangiectasia in eyes and lymphoreticular neoplasms are common. Ataxia telangiectasia mutated (ATM) gene is located at chromosome 11q. The mutated gene is present in 1% of total population. The disease is manifested in 1:40,000 persons. Other such defects are summarized in Box 40.2.
Telomere and Telomerase

i. The replication always takes place from 5' to 3' direction in the new strand. The DNA polymerase enzyme is not able to synthesize the new strand at the 5' end of the new strand. In other words, a small portion (about 300 nucleotides) in the 3' ends of the parent strands could not be replicated (Fig. 40.19).

ii. This end piece of the chromosome is called telomere. Therefore, another enzyme, telomere terminal transferase or telomerase takes up this job of replication of the end piece of chromosomes.

iii. After the normal replication, there is only single strand in this region; so this portion is degraded by exonucleases. This broken end leads to aberrant recombinations or end to end fusions. Unless there is some mechanism to replicate telomeres, the length of the chromosomes will go on reducing at each cell division (genes loss). The stability of the chromosome is thus lost.

iv. The shortening of telomere end is prevented by an enzyme telomere terminal transferase or telomerase. It contains an essential RNA component, which provides the template for telomerase repeat synthesis.

v. Telomerase acts like a reverse transcriptase. Telomerase recognises 3' end of telomere, and then a small DNA strand is synthesized.

vi. Terminal restriction fragments from 70-year old donors are shorter than those from 20-year old ones. Thus, in old age, the telomerase activity is lost; leading to chromosome instability and cell death.

vii. As a general rule, cancer cells have continued presence of telomerase, and the chromosome length equilibrium is maintained, leading to continued cell division. As cancer cells have increased and persistent activity of telomerase, the cancer cells become immortal. Premature shortening of telomeres is seen in some types of aplastic anemia. Elizabeth Blackburn, Carol Greider and Jack Szostak discovered the telomeres and telomerase, all the three were awarded Nobel prize in 2009.

Hydrolysis of DNA

i. Those enzymes which hydrolyse only from the end of the DNA molecule are called exonucleases.

ii. Those enzymes which hydrolyse the internal phospho diester bonds are called endonucleases.

iii. Certain endonucleases cut at specific sequences of DNA; these "molecular scissors" are called restriction endonucleases (RE) (see Chapter 43).

Inhibitors of DNA Replication

Certain compounds will inhibit bacterial enzymes, but will not affect human cells; such drugs are useful as anti-bacterial agents.

Some other compounds will inhibit human enzymes, they will arrest new DNA synthesis, and arrest the cell division. Those drugs are therefore useful as anti-cancer agents. A list of such drugs is given in Box 40.3.
Chapter 41: Transcription and Translation

### RIBONUCLEIC ACID

Ribonucleic acid (RNA) is also a polymer of purine and pyrimidine nucleotides linked by phosphodiester bonds. However RNA differs from DNA as shown in Table 41.1 and Figure 41.1. About 50% of cellular RNA is distributed in the ribosomes and endoplasmic reticulum; 25% in cytoplasm; 15% in mitochondria and the rest 10% in nucleus. Cellular RNAs are of 5 types:

### TRANSCRIPTION AND TRANSLATION

- **a. Messenger RNA (mRNA).** The gene present in DNA is transcribed into mRNA. This constitutes about 2-5% of total RNA in the cell. They are generally degraded quickly.
- **b. Ribosomal RNA (rRNA).** This constitutes about 80% of all RNA in the cell. 28S, 18S and 5S are the major varieties. They are involved in the protein biosynthesis. They are very stable.
- **c. Transfer RNA (tRNA).** There are about 60 different species present. They constitute about 15% of the total RNA in the cell. They are very stable.
- **d. Small RNA.** They constitute about 1-2% of total RNA in the cell. There are about 30 different
varieties. They are very stable. **Small Nuclear RNAs** (SnRNAs) are a subgroup of small RNA. Some important species of SnRNAs are U1 (165 nucleotides), U2 (188 nucleotides), U3 (216), U4 (139), U5 (118), U6 (106). They are involved in mRNA splicing.

e. Micro-RNA (miRNA). They alter the function of mRNA. They are moderately stable. More details are given at the end of this chapter.

**Central Dogma of Molecular Biology**

As shown in Figure 41.2, the information available in the DNA is passed to messenger RNA, which is then used for synthesis of a particular protein.

**Replication, Transcription and Translation**

i. DNA replication is like printing a copy of all the pages of a book. The replication process occurs only at the time of cell division.

ii. But transcription is taking place all the time. Only certain areas of the DNA are copied (selected regions on the sense strand). This is like taking xerox copy of particular page of the book. So, the genetic information of DNA is transcribed (copied) to the messenger RNA (mRNA). During transcription, the message from the DNA is copied in the language of nucleotides (4 letter language).

iii. The mRNA then reaches the cytoplasm where it is translated into functional proteins (Fig. 41.2). During translation, the nucleotide sequence is translated to the language of amino acid sequence (20 letter language) (Fig. 41.2).

**Template and Coding Strands**

i. The template strand is transcribed to give rise to mRNA. The template strand has the complementary sequence of mRNA.

ii. The opposite strand has the same sequence as the mRNA. The DNA strand having the same sequence of mRNA is called coding strand (Fig. 41.3). As it is complementary to the template strand, it is also called anti-template strand or nontemplate strand.

**Messenger RNA or mRNA**

i. It acts as a messenger of the information in the gene in DNA to the protein synthesizing machinery in cytoplasm. It carries the message to be translated to a protein.

ii. The template strand of DNA is transcribed into a single stranded mRNA. This is accomplished by the DNA dependent RNA polymerase.

iii. The mRNA is a complementary copy of the template strand of the DNA (see Fig. 41.3).

iv. However, thymine is not present in RNA; instead uracil will be incorporated.

**Fig. 41.3.** Transcription. The mRNA base sequence is complementary to that of the template strand and identical to that of the coding strand. In mRNA, U replaces T.

**Fig. 41.4.** Genes may be on any strand of DNA. Transcription is in 3' to 5' direction of the template strand.

**Fig. 41.5.** Transcription process.
v. In the DNA, one strand will harbor certain genes, while others are borne by the other strand (Fig. 41.4).

vi. A **transcription unit** is the region of DNA that includes not only the gene for mRNA synthesis, but also the initiator, promoter, and terminator regions as well as the introns. The mRNA that is initially produced is called **primary transcript**.

1. **TRANSCRIPTION PROCESS**

Roger Kornberg got Nobel prize in 2006 for his studies on molecular basis of transcription. He is son of Arthur Kornberg (Nobel Prize 1959) who worked on DNA replication. Transcription includes initiation, elongation, and termination steps followed by post-transcriptional processing. A summary is shown in Figure 41.5.

1-A. Mammalian RNA Polymerases

There are 3 different DNA dependent RNA polymerases (RNAP) in higher organisms. They have molecular weight 500 to 600 kDa.

i. **RNAP type II or B** is the main enzyme synthesizing mRNAs. It is inhibited by alpha amanitin (a toxin from the mushroom *Amanita phalloides*). Amanitin blocks the translocation of RNAP during mRNA synthesis. SnRNA and miRNA are also synthesized by the same RNAP B. RNAP has two large and 12 smaller subunits. Phosphorylation activates RNAP II.

ii. **RNAP type I or A** is responsible for synthesis of rRNA (ribosomal); it is not inhibited by amanitin.

iii. **RNAP type III or C** is responsible for production of tRNA; it is moderately sensitive to amanitin.

1-B. Bacterial RNA Polymerase

Bacterial RNAP enzyme contains two alpha, two beta subunits, one omega subunit and one sigma factor and two zinc molecules. Beta subunit fixes at the initiation site. The sigma factor recognises the promoter site and increases the affinity of the holo-enzyme to the promoter site.

2. **Signals for Initiation of Transcription**

2-A. Promoters

There are certain specific areas on the DNA that act as starting signals for initiation process. The RNAP attaches at the promoter site on the template DNA strand. In human beings, about $10^6$ transcription initiation sites are present on the entire DNA.

2-B. TATA Box in Prokaryotes

In the case of bacteria, about 35 bp upstream of the transcription start site, there is a sequence of 5'-TGTTGACA-3'. About 10 bp upstream, there is another sequence 5'-TATAAT-3'. The second one is referred to as **TATA box** or Priboon box. The TATA box is not on template strand, but on coding strand.

2-C. Golberg-Hogness Box in Eukaryotes

In mammals, the exact sequence in TATA box is slightly different (TATAAA) and is known as Golberg-Hogness box. It is located at –25 to –30 position. It acts as signal for the start region. Further upstream, between –70 and –80, there is another sequence GGCAATCT, known as CAAT box. These recognition signals are said to be **cis-acting**, as they are near to the gene.

2-D. Enhancers and Silencers

**Enhancers** increase the rate of transcription and **silencers** decrease the rate. Other regulatory signals for transcription are **Hormone response elements (HRE)** (Chapter 44), Repressors, Inducers and Derepressors (Chapter 42).

3. **Initiation of Transcription**

3-A. Bacterial System

i. The starting point of transcription corresponds to the 5' nucleotide of the DNA, designated as +1. Then numbering is done 2, 3, 4, etc. to the downstream region of the DNA. The nucleotide adjacent to downstream of the starting point is numbered as –1. Further upstream, these negative numbers are increased.

ii. The DNA helix partially unwinds, and the RNAP binds with the promoter site on DNA with the help of sigma factor (Fig. 41.7). This is called **pre-initiation complex** (PIC).

iii. When it reaches the appropriate site on the gene, the first nucleotide of the mRNA attaches to the initiation site on the beta subunit of RNAP. This becomes the 5' end of the mRNA. It will be complementary to the base present in the DNA at that site. This is the **initiation of transcription**. Generally, a purine ribonucleotide is the first unit in the nascent mRNA.

iv. The next nucleotide attaches to the RNAP. A phosphodiester bond is formed. Then the enzyme moves to the next base on the template DNA (see Fig. 41.6).

v. After 10-20 nucleotides are polymerized, the RNAP undergoes conformational change, and moves away from the promoter region. This is called **promoter clearance**. Sigma factor is now released and the gene is fully transcribed.

3-B. Mammalian System

In eukaryotes, the situation is more complex. There are at least 7 **transcription factors**, collectively called as TH-II. First, the TATA box is recognized...
by TBP (TATA binding protein). Instead of the sigma factor, SL1 factor ensures that RNAP could locate the start point. In humans about $10^5$ transcription initiation sites are available.

The human TATA box binds TATA-binding protein (TBP), which has many subunits. TBP-associated factors (TAF) bind with TBP to form TFIID. Binding of TFIID complex to the TATA box is the first step in the transcription process. Other proteins associated with this process are, TFIIA, B, E, F, H and polymerase II. The whole complex spans DNA from position –30 to +30. Moreover other proteins, known as general transcription factors (GTFs) facilitate promoter specific binding to form pre-initiation complex in mammals. Three classes of transcription factors are involved in transcription of mammalian genes. These are:

- Basal components, such as TBP, TFIIA, B, E, F and H.
- Co-regulators, such as TAFs, TFIID, Meds, Chromatin modifiers.
- Activators, such as SP1, ATF, AP1.

4. Elongation Process of Transcription

i. The RNAP moves along the DNA template. New nucleotides are incorporated in the nascent mRNA, one by one, according to the base pairing rule (Fig. 41.8). Thus A in DNA is transcribed to U in mRNA; T to A; G to C and C to G.

ii. The synthesis of mRNA is from 5’ to 3’ end. That means the reading of template DNA is from 3’ to 5’ (Fig. 41.3). This is analogous to the polarity in DNA synthesis.

iii. As the RNAP moves on the DNA template, the DNA helix unwinds downstream and winds at the upstream areas. RNAP has the DNA unwinding property. Topo-isomerase will also help in this unwinding process. A transcription bubble containing RNAP, DNA and nascent RNA is formed (Fig. 41.7). This bubble is about 20 bp length.

iv. RNAP has no nuclease activity; so there is no proof reading. Hence fidelity is less; mistake rate in mRNA transcription is $10^4$ or $10^5$ times more than DNA replication. But it is less serious, since these mistakes are not transmitted to the daughter cells or to the next generation.

5. Termination of Transcription

The specific signals are recognized by a termination protein, the Rho factor (abbreviated with Greek letter, "ρ"). The attachment is ATP dependent process. When it attaches to the DNA, the RNAP cannot move further. So, the enzyme dissociates from DNA and consequently newly formed mRNA is released (Fig. 41.9). Rho independent termination is also described.

In humans, the termination signals exist far downstream of the coding sequence, usually 1000 to 2000 bases away.

6. Post-transcriptional Processing

i. The mRNA formed and released from the DNA template is known as the primary transcript. It is also known as heteronuclear mRNA or hnRNA.

ii. In mammalian system, it undergoes extensive processing to become the mature mRNA. These modifications are:

- Endonuclease cleavage
- Poly-A tailing
c. 5' capping
d. Methylation
e. Removal of introns
f. Splicing of exons (connect together). These processings occur mainly in the nucleoplasm.

iii. In bacteria, mRNA is not changed; and translation of mRNA starts even before completion of transcription.

iv. Post-transcriptional processing is not only for mRNA but for tRNA and rRNA as well.

6-A. Poly-A Tailing at 3' End
The 3' terminus is polyadenylated in the nucleoplasm (Fig. 41.10). This poly-A tail may be 20 to 250 nucleotides long. This tail protects mRNA from attack by 3' exonuclease.

6-B. Capping at 5' End
Eukaryotic mRNAs are all 'capped' at the 5' terminus by 7-methyl guanosine triphosphate. An unusual 5' to 5' triphosphate bridge is seen. This is also done inside the nucleus. The cap is useful in recognition of mRNA by the translating machinery.

6-C. Methyations
Methylations of N6 of adenine residue and 2'-hydroxyl group of ribose are common. These are mainly done in the cytoplasm.

7. Removal of Introns
i. The primary transcripts are very long; they have molecular weights more than $10^7$. Molecular weight of mature mRNA is about $1-2 \times 10^6$. This means large portions of hnRNA are cleaved off.

ii. The primary transcript contains coding regions (exons) interspersed with noncoding regions (introns).

iii. These intron sequences are cleaved and the exons are spliced (combined together) to form the mature mRNA molecule. This processing is done in nucleus (see Figure 41.10). Splicing is an energy requiring process.

Small Nuclear RNAs (snRNAs)
Their size ranges from 90-300 nucleotides. They are named as U1, U2, U4, U5, U6 and U7. The U stands for the uracil rich nature of the snRNAs. They take part in the formation of spliceosomes. All of them are located in the nucleus. They complex with specific proteins, to form small nuclear ribonucleoprotein particles (SnRNPs). It is pronounced as "Snurps". Production of autoantibodies against "Snurps" cause systemic lupus erythematosis (SLE), a fatal autoimmune disease.

Spliceosomes
SnRNPs associated with hnRNA at the exon-intron junction form spliceosomes. This is taking place inside the nucleus. Cuts are made at both ends of intron; it is removed; and exon-exon ends are ligated at G-G residues (Fig. 41.11). For elucidation of spliceosome activity, Richard Roberts and Phillip Sharp were awarded Nobel prize in 1993.

Ribozymes
i. Enzymes made up of RNA are called ribozymes. Ribozymes or RNA enzymes are catalytic RNA
molecules with sequence specific cleavage activity. They also exhibit Michaelis-Menten kinetics. Thomas Cech and Sidney Altman discovered the ribozymes, for which they were awarded Nobel prize in 1989.

ii. In the pre-cellular epoch, nucleic acids were biological catalysts; and in course of evolution, proteins took up this activity. In that sense, the ribozymes are vestigial remnants.

iii. Spliceosomes contain ribozymes as well as protein components which serve to stabilize the structure of ribozymes.

iv. RNAse-P is another ribozyme, which generates the ends of tRNAs.

v. Peptidyl transferase present in ribosomes (used for protein biosynthesis) is another example of ribozyme.

Alternative splicing
One form of gene regulation is the differential processing of mRNA. Suppose there are exons 1, 2 and 3. The splicing can be 1-2, 1-3, 2-3, etc. In one type of beta thalassemia, there is a mutation in the exon-intron junction, so that one intron is not removed, leading to absent synthesis of beta chain. The sequence of glucokinase (GK) gene has 10 exons and 9 introns. But expression of GK gene is regulated differently in liver and pancreas, because of 2 different promoters in these two tissues; these are produced by differential splicing of exons.

Alternate editing of mRNA
ApoB gene is transcribed into and mRNA that leads to synthesis of 100 kDa protein in liver, which is called apoB100. In intestine the same primary transcript is formed; but a cytidine deaminase converts a CAA codon in the mRNA into UAA codon; thus codon for glutamine is changed to a termination codon, producing a 49 kDa protein; this is apoB48.

Untranslated regions of mRNA
Protein synthesis is often regulated at the level of initiation of translation, making it a critical step. This regulation occurs by both the cis-regulatory elements, which are located in the 5'-and 3'-UTRs (untranslated regions), and trans-acting factors. A breakdown in this regulation machinery can perturb cellular metabolism, leading to various physiological abnormalities. The highly structured UTRs, along with features such as GC-richness, upstream open reading frames and internal ribosome entry sites, significantly influence the rate of translation of mRNAs. Changes in the cis-regulatory sequences of the UTRs, for example, point mutations and truncations, influence expression of specific genes at the level of translation. Such modifications may tilt the physiological balance from healthy to diseased states, resulting in conditions such as hereditary thrombocytopenia, breast cancer, fragile X syndrome, bipolar affective disorder and Alzheimer’s disease. This shows the crucial role of UTRs, perhaps as much as that of coding sequences, in health and disease.

Reverse Transcriptase
i. Generally speaking, the genes are made up of DNA. Usually, DNA dependent RNA polymerase transfers the information of DNA to mRNA. However, genetic materials of some animal and plant viruses are made up of RNA.

ii. Retrovirus is a subgroup of RNA viruses. The human immunodeficiency virus (HIV) causing AIDS is a retrovirus. Here the RNA acts as a template. Based on this RNA, the enzyme, RNA dependent DNA polymerase or reverse transcriptase will make a new DNA strand. Temin and Baltimore isolated this enzyme in 1970 and they were awarded the Nobel prize in 1975.

iii. From the RNA-DNA hybrid, the RNA part is hydrolysed by a specific RNAse-H. The remaining DNA acts as a template to produce double stranded DNA. Thus genetic information is transferred from RNA to DNA (Fig. 41.12).
Some of the tumor viruses were also shown to possess reverse transcriptase. The presence of the enzyme may be taken as an indication of a retrovirus infection.

**Inhibitors of RNA Synthesis**

*Actinomycin D* and *Mitomycin* intercalate with DNA strands, thus blocking transcription. They are used as anticancer drugs. *Rifampicin* is widely used in the treatment of tuberculosis and leprosy (Natural antibiotic rifamycin is produced from streptomyces). Other inhibitors of RNA synthesis are shown in Table 41.2.

**PROTEIN BIOSYNTHESIS**

The DNA is *transcribed* to mRNA which is *translated* into protein with the help of *ribosomes*. This is summarized in Figure 41.13.

**Transfer RNA (tRNA) or (sRNA)**

i. They transfer amino acids from cytoplasm to the ribosomal protein synthesizing machinery; hence the name transfer RNA.

ii. Since they are easily soluble, they are also referred to as *soluble RNA* or sRNA. They are RNA molecules present in the cytoplasm.

iii. Each molecule is only 73-93 nucleotides in length; much shorter than mRNA molecules.

iv. When transcribed, the tRNA molecules are large and they undergo post-transcriptional modifications.

**A. Structure of tRNA Molecule**

i. The transfer RNAs show extensive internal base pairing and acquire *clover leaf* like structure (Fig. 41.14A).

ii. They contain a significant proportion of *unusual bases*. These include dihydrouracil (DHU) (Fig. 39.4), pseudouridine (ψ) (Fig. 39.9), and hypoxanthine (Fig. 39.2). Moreover many bases are methylated.

**B. Acceptor Arm is at the 3’ End**

It carries the amino acid (Fig. 41.14-A). This area has 7 base pairs. The end sequence is **CCA-3’**. The 3’ end hydroxyl group is forming an ester bond with the carboxyl end of amino acids.

**C. Anticodon Arm of tRNA**

At the opposite side of the acceptor arm is the anticodon arm (Fig. 41.14-B). It recognizes the triplet nucleotide codon present in mRNA. The specificity of tRNA resides in the anticodon site, which has *base sequences complementary to that of mRNA codon*.

For example, if the mRNA has a codon with the sequence UUU, the anticodon sequence of the tRNA will be AAA, by which it base pairs with mRNA codon. So the specific tRNA can bind correctly to the mRNA codons. In this case, the **UUU codon is translated as phenylalanine**. Recognition of codon by the tRNA anticodon is illustrated in Figure 41.14B.

Fig. 41.13. Expression of a gene into a protein
The tRNA molecule will show specificity in both aspects; in recognizing the mRNA codon as well as in accepting the specific amino acid coded by that codon. In this way the tRNA molecules play a pivotal role in translation.

The tRNAs act as adapter molecules between mRNA and the amino acids coded by it. The nucleotides of codons have no affinity for amino acids. So the tRNA molecules act as mediators between the mRNA and amino acids. Methionine-tRNA was isolated by Paul Berg in 1956 (Nobel prize, 1980). The complete sequencing of alanine-tRNA was done by Robert Holley in 1963 (Nobel prize 1968). Khorana (Indian born US scientist) got Nobel prize in 1968, for synthesizing the gene for alanine tRNA.

D. DHU Arm of tRNA
The D arm or DHU region is so named due to the presence of a dihydro uridine in that area (Fig. 41.14A). The DHU arm serves as the recognition site for the enzyme which adds the amino acid.

E. Pseudouridine Arm of tRNA
The opposite arm is called pseudouridine arm, as it contains a pseudouridine. It is generally denoted with the Greek alphabet “ψ” which is pronounced as “psi” (Fig. 41.14A). It is involved in binding tRNA to ribosomes. About 75% of tRNA molecules possess a short extra arm, about 3 to 5 base pairs long and they belong to Class 1. The tRNA molecules belonging to Class 2, have a long extra arm, 13 to 21 base pairs in length.

F. Processing of tRNA
The tRNA is synthesized as a long precursor and is trimmed by Ribonuclease P, a ribozyme. The CCA sequence is added at 3’ end and bases are modified.
Ribosomal RNA (rRNA)

Ribosomes provide necessary infrastructure for the mRNA, tRNA and amino acids to interact with each other for the translation process. Thus ribosomal assembly is the protein synthesizing machinery. Nucleolus is the area where rRNA is synthesized and ribosomal assembly is produced. For studies on structure and function of ribosomes, Nobel prize was awarded in 2009 to Venkataraman Ramakrishnan (born in India), Ada Yonath and Thomas Steitz.

A. Components of rRNA

The mammalian ribosome has a sedimentation velocity of 80S unit. It has a larger 60S subunit and another smaller 40S subunit. They contain different rRNAs and specific proteins. Ribosomal RNA has catalytic activity. Peptidyl transferase activity is carried out by 28S RNA which acts as a ribozyme.

B. Bacterial Ribosomes are Different

Bacterial ribosomes are smaller than mammalian ones. Bacteria has 70S ribosomes; with 30S and 50S subunits. So, many antibiotics will inhibit bacterial protein synthesis, but will do no harm to human cells. See end of this Chapter.

C. Processing of rRNA

The rRNA is also synthesized as a 45S precursor which is cleaved to 28S, 18S, 5.8S and 5S rRNAs. The large ribosomal subunit has 28S, 5.8S and 5S rRNA and small ribosomal subunit has only 18S rRNA.

Genetic Code

A triplet sequence of nucleotides on the mRNA is the codon for each amino acid. Since there are four different bases, they can generate 64 \((4^3)\) different codons or code words by permutations and combinations. For example, the codon for phenyl alanine is UUU. Nirenberg was awarded the Nobel prize in 1968 for deciphering the genetic code. There are 31 tRNA species, carrying 20 amino acids, which translate 61 codons. Important features of genetic code are shown in Box 41.1.

Salient Features of the Genetic Code

i. Triplet Codons

The codes are on the mRNA. Each codon is a consecutive sequence of three bases on the mRNA, e.g. UUU codes for phenylalanine (Table 41.3).

ii. Nonoverlapping

The codes are consecutive. Therefore the starting point is extremely important. The codes are read one after another in a continuous manner, e.g. AUG, CAU, GAU, etc.

iii. Nonpunctuated

There is no punctuation between the codons. It is consecutive or continuous.

iv. Degenerate

Table 41.3 shows that 61 codes stand for the 20 amino acids. So one amino acid has more than one codon. For example, serine has 6 codons; while glycine has 4 codons. This is called degeneracy of the code. Generally speaking, if the amino acid has more than one codon, the first two bases in the codon will be the same, only the third one is different. This reduces the effect of mutations.

v. Unambiguous

Though the codons are degenerate, they are unambiguous; or without any doubtful meaning. That is, one codon stands only for one amino acid.

Table 41.3. Triplet codons and corresponding amino acids
vi. Universal
The codons are the same for the same amino acid in all species; the same for "Elephant and E.coli". The genetic code has been highly preserved during evolution.

vii. Wobbling Phenomenon
The reduced stringency between the third base of the codon and the complementary nucleotide in the anticodon is called wobbling. The pairing of codon and anticodon can wobble at the third letter. For example, GGU, GGC and GGA are the codes for glycine; all three will pair with the anticodon CCI (I = Inosinic acid) of glycine-tRNA. The degeneracy of genetic code and wobbling phenomenon together will reduce the effect of mutations.

viii. Terminator Codons
There are three codons which do not code for any particular amino acids. They are "nonsense codons", more correctly termed as punctuator codons or terminator codons. They put "full stop" to the protein synthesis. These three codons are UAA, UAG, and UGA. UGA is a stop codon; but in special circumstances, it stands for seleno-cysteine (the "21st" amino acid).

ix. Initiator Codon
In most of the cases, AUG acts as the initiator codon. AUG also acts as the codon for methionine. In a few proteins, GUG may be the initiator codon.

Mitochondria have different codes
The protein synthesising machinery of mitochondria is distinct from that in the cytoplasm. There are only about 22 tRNAs in mitochondria; but there are 31 tRNA species in cytoplasm.

TRANSLATION PROCESS
Translation is a cytoplasmic process. The mRNA is translated from 5' to 3' end. In the polypeptide chain synthesized, the first amino acid is the amino terminal one (Fig. 41.13). The chain growth is from amino terminal to carboxyl terminal. The process of translation can be conveniently divided into the phases of:
A. activation of amino acid
B. initiation
C. elongation
D. termination and
E. post-translational processing.

A. Activation of Amino Acid (Charging reaction)
i. The enzymes aminoacyl tRNA synthetases activate the amino acids. The enzyme is highly selective in the recognition of both the amino acid and the transfer RNA acceptor. There is at least one tRNA for each of the 20 amino acids.

ii. The D arm of tRNA is very important for the recognition by the enzyme. The CCA 3' terminus of the acceptor arm carries amino acid (Figs 41.14A and B).

iii. Amino acid is first activated with the help of ATP. Then the carboxyl group of the amino acid is esterified with 3' hydroxyl group of tRNA.

\[
\text{Amino acyl tRNA synthetase} \\
\text{Amino acid} \quad \text{Aminoacyl tRNA} \\
+ \text{tRNA} + \text{ATP} \quad + \text{AMP}
\]

Fig. 41.15. Initiation steps; UAC= anticodon on met-tRNA; AUG= start signal; P= peptidyl site; A= aminoacyl site
This is a two-step reaction. First reaction is the formation of AMP-amino acid-enzyme complex. In the second reaction, this activated amino acid is transferred to the corresponding tRNA molecule. The AMP and enzyme are released.

iv. In this reaction, ATP is hydrolysed to AMP level, and so two high energy phosphate bonds are consumed.

B. Initiation of Protein Synthesis

Initiation can be studied as 4 steps: 1. Recognition steps. 2. Formation of pre-initiation complex, i.e. binding of ternary complex of met-tRNA, GTP and eIF-2 to 40S ribosome. 3. Binding of mRNA to the pre-initiation complex to form 43S initiation complex. 4. The 43S initiation complex is combined with the 60S ribosomal subunit to form 80S initiation complex.

B-1. Recognition Steps

In eukaryotes, the first amino acid incorporated is methionine (AUG codon). But in prokaryotes, the same codon stands for N-formyl methionine, which is the first amino acid.

The first AUG triplet after the marker sequence is identified by the ribosome as the start codon. In mammalian cells, the marker is the “Kozak” sequence; in bacteria, it is the “Shine-Dalgarno” sequence. For the process, initiation factors (eIF) are required; their properties are summarized in Table 41.4. The letter “e” is shown to differentiate eukaryotic initiation factors from those of bacterial factors.

Poly-A tail of the mRNA and its binding protein, PAB1 are also important for the recruitment of 40S ribosomal subunit to the mRNA. PAB1 attaches to the poly-A tail, then interacts with eIF-4F that is bound to the cap of mRNA. This helps in the attachment of 40S ribosomal subunit to the 5’ end of mRNA.

B-2. Formation of 43S Pre-initiation Complex

GTP, IF-2, met-tRNA (tRNA carrying methionine) and 40S ribosomal subunit are complexed to form pre-initiation complex (Fig. 41.15). This is the 43S pre-initiation complex. This is stabilized by eIF-3 and eIF-1A. Met-tRNA has the anticodon UAC.

There are 2 tRNAs for methionine; one for methionine for the initiator codon; the second one for methionine in the internal part of proteins. IF-2 is a control point for protein synthesis. It has 4 subunits; the alpha unit is phosphorylated by different protein kinases, HCR, PKR, PERK and GCN2. During virus infection, these kinases are activated, and protein synthesis as a whole (including virus proteins) is inhibited.
B-3. Formation of 43S Initiation Complex
This pre-initiation complex binds with mRNA; the 5' methylated cap of mRNA facilitates this binding. **Initiation factors** 4A, 4B, 4E, 4F and 4G are necessary for this binding. It also requires energy from hydrolysis of ATP. This forms initiation complex (Fig. 41.15).

IF-3 binds with 4F and links the complex with 40S subunit of ribosome. The 4E is important in controlling the rate of protein translation. The 4E is responsible for recognition of the mRNA cap, and this is the **rate limiting step** in the whole of translation process. Insulin and growth factors phosphorylate one serine residue of the 4E. Phosphorylated 4E avidly binds the cap of mRNA, so that translation is enhanced. Another set of proteins (BP1, PHAS1, BP2, BP3, etc.) will bind and inhibit 4E. Insulin phosphorylates BP1, which results in dissociation of 4E and BP1, and the inhibition of BP1 is removed. Thus insulin increases translation process. Insulin is anabolic.

B-4. Formation of 80S Ribosomal Assembly
The 48S initiation complex now binds with 60S ribosomal unit to form the full assembly of 80S ribosome. This needs hydrolysis of GTP; this hydrolysis is effected by IF-2 and IF-5. Then all initiation factors are released from 48S initiation complex (Fig. 41.15).

**P and A Sites of Ribosomal Assembly:** The whole ribosome contains two receptor sites for tRNA molecules. The “P” site or peptidyl site carries the peptidyl-tRNA. It carries the growing peptide chain. The “A” site or aminoacyl site carries the new incoming tRNA with the amino acid to be added next. When the 80S ribosome is assembled, the tRNA-Met is now at the P site. The anti-codon of met-tRNA is correctly base pairing with the AUG codon on mRNA (Figs 41.15 and 41.16). A third site (E site) or exit site is occupied by the deacylated tRNA.

C. Elongation Process of Translation
Elongation has 3 steps: 1. Binding of aminoacyl tRNA to the A site. 2. Peptide bond formation and 3. Translocation of the ribosome on the mRNA.

C-1. Binding of New Aminoacyl tRNA
A new aminoacyl tRNA comes to the "A" site. The next codon in mRNA determines the incoming amino acid. **Elongation factor-1 (EF-1)** (Table 41.4) and **GTP** are complexed with the incoming aminoacyl tRNA. The GTP is hydrolysed to GDP, the tRNA binds to the "A" site and EF-1 is released (Fig. 41.16).

C-2. Peptide Bond Formation
i. The alpha amino group at the incoming amino acid in the "A" site forms a peptide bond (CO-NH) with carboxyl group of the peptidyl tRNA occupying the "P" site. This reaction is catalyzed by the enzyme **peptidyl transferase** (28S rRNA, a component of 60S subunit). This is an example of ribozyme; RNA acts as the enzyme.

ii. Since the amino acid brought in by the tRNA is already activated, there is no need for further energy supply for the purpose of peptide bond formation. Now the growing peptide chain is occupying the "A" site (Fig. 41.16).

C-3. Translocation Process
i. At this time, the tRNA fixed at the "P" site does not carry any amino acid and is therefore released from the ribosome. Then the whole ribosome moves over the mRNA through the distance of one codon (3 bases). The peptidyl tRNA is translocated to the "P" site; this is done with the help of **elongation factor 2 (EF2)**.

ii. The "A" site is ready to receive another aminoacyl tRNA bearing the appropriate anticodon. The new aminoacyl tRNA is fixed to the "A" site, by base pairing with the mRNA codon. Translocation requires hydrolysis of GTP to GDP (Fig. 41.16).

iii. The elongation reactions (steps C-1, C-2 and C-3 above) are repeated till the polypeptide chain synthesis is completed.

D. Energy Requirements
For each peptide bond formation, **4 high energy phosphate bonds are used**; two for the initial activation and one for EF-1 step (GTP to GDP) and one for EF-2 step (GTP to GDP). Actual peptide bond formation (peptidyl transferase step) **does not require** any energy, because the amino acids are already activated. Further, 1 ATP is used for initiation complex formation; 1 GTP for 80S ribosome formation and 1 GTP for termination.

E. Termination Process of Translation
i. After successive addition of amino acids, ribosome reaches the **terminator codon** sequence (UAA, UAG or UGA) on the mRNA. Since there is no tRNA bearing the corresponding anticodon sequence, the "A" site remains free.
ii. The **releasing factor 1** (RF1) enters this site. The RF1 binds with RF3 and GTP. This complex hydrolyses the peptide chain from the tRNA at the P site, with hydrolysis of GTP to GDP. The completed peptide chain is released.

iii. Finally, 80S ribosome **dissociates** into its component units of 60S and 40S (Fig. 41.17).

**Polyribosomes**
One eukaryotic ribosome can synthesise 5 to 6 peptide bonds per second. Many ribosomes can work on the same mRNA molecule simultaneously and these aggregates are called polyribosomes or polysomes (Fig. 41.18). In such cases each ribosome will be about 80 to 100 nucleotides apart on the mRNA. Polyribosomes may be attached on the walls of the endoplasmic reticulum to form the rough ER (Chapter 2). The proteins are then transported through cisternal space to Golgi apparatus, where they are temporarily stored. Cytoplasmic proteins are synthesized by ribosomes that exist free in cytoplasm.

**Protein Targetting**

i. **Proteins for external secretion**
The process is also called as "protein sorting" or "protein localization". The secreted proteins, plasma membrane integral proteins, lysosomal enzymes and membrane proteins of ER are synthesized on rough endoplasmic reticulum by membrane bound polyribosomes. The newly synthesized protein is then delivered to the destined compartment. Blobel and Sabatini proposed the **signal hypothesis** to explain the different destination of proteins. Guenter Blobel was awarded Nobel prize in 1999.

The secretory proteins contain a **signal peptide** (SP) region of about 12 to 35 amino acids, located in the **amino terminal region** (Fig. 41.20). This signal peptide will cause anchoring of ribosomes on ER. Initially one free ribosome in the cytoplasm attaches on the mRNA and a small part about 70 amino acids in length, including the SP region, is synthesized.

Another **signal recognition particle** (SRP) is now attached to the SP region, that blocks further protein synthesis. SRP-SP ribosome complex then binds to a **docking protein** or receptor (SRPR) available on ER. Only then the block is removed and remaining portion of the protein is synthesized. By this mechanism, the signal peptide directs the ribosome to be attached on the ER (Fig. 41.20). The arrangement of the docking protein on ER is such that, the nascent protein is passed through the membrane into the channels of ER. Later, the signal region is cleaved off by **signal peptidase**. Then protein synthesis is completed, and the protein molecule is now inside the endoplasmic membrane (Fig. 41.20). As the nascent protein is traversing the inner membrane of ER, carbohydrate moieties are added at particular regions by specific enzymes; this is called **co-translational glycosylation**.

ii. **Proteins for internal parts of the cell**
Proteins destined to become proteins of cytosol, mitochondria and peroxisomes are lacking this signal sequence. Hence they are synthesized on **free ribosomes**. After completion of synthesis, they do not enter the lumen of ER, but are available in the cytoplasm.

iii. **Correct address of destination is labelled**
The signal peptide is on the amino terminal region of protein. Apart from that, the proteins carry an "address" that is specific for its correct destination inside the cell. This is present in the **carboxy terminal** end of proteins. For example, proteins possessing the amino acid sequence KDEL (Lys-asp-glu-leu) near the C-terminal end are destined to reach the **luminal surface of ER**. Integral **membrane proteins** of ER have amino acid sequences acting as a stop signal, which prevents escape of proteins from ER. Proteins destined to reach peroxisomes contain **peroxisome target sequence** (PTS) with 26-36 amino acids. Nuclear proteins and ribosomal proteins, which are imported into the nucleus, contain certain **nuclear import signal sequences**. The nuclear transport is energy requiring and is aided by the two cytoplasmic proteins, alpha-importin (60 kD) and beta-importin (90kD). Diseases due to defective protein targeting are shown in Box 41.2.
Post-translational Processing

A. Proteolytic cleavage
Modification of polypeptides by partial proteolysis, e.g. conversion of pro-insulin to insulin (Fig. 41.19). See also Chapter 4.

B. Modifications of amino acids

i. **Gamma carboxylation** of glutamic acid residues of prothrombin, under the influence of vitamin K (Chapter 33).

ii. **Hydroxylation** of proline and lysine in collagen with the help of vitamin C (Chapter 52).

iii. **Phosphorylation** of hydroxyl groups of serine, threonine or tyrosine by kinases, e.g. glycogen phosphorylase.

iv. **Cotranslational glycosylation**: Carbohydrates are attached to serine or threonine residues through O-glycosidic linkages and to asparagine or glutamine residues through N-glycosidic linkages (Box 41.3).

C. Subunit aggregation

Examples are immunoglobulin, hemoglobin and maturation of collagen. Failure of post-translational modification affects the normal function of many proteins.

---

**Box 41.2. Protein Targetting**

Zellweger syndrome is due to defective oxidation of very long chain fatty acids (VLCA). Here the correct "address" is not printed on the protein packet; so that it could not be delivered to the correct locality. Peroxisomal enzymes are produced; but their entry into peroxisome is denied. This leads to insufficient oxidation of VLCA. Accumulation of VLCA in CNS causes neurological impairment and death in childhood.

Another example is the primary hyperoxaluria, which causes kidney stones at an early age. The defect is due to protein targeting defect and the enzyme alanine glyoxylate amino transferase (Fig. 15.7) is seen in mitochondria, instead of its normal peroxisomal location.

Some forms of familial hypercholesterolemia are due to deficient transport signals. Cause of cystic fibrosis include improper localization of proteins.

Inclusion cell disease is due to non-entry of normal enzymes into lysosomes. Mannose-6-phosphate is the marker to target enzymes to lysosomes; this is absent.

proteins. For example, poor cross-linking of collagen in scurvy, since ascorbic acid is required for the hydroxylation of proline and lysine (Chapters 34 and 52).

D. Protein folding and chaperones

When a protein is being synthesized, it may assume different three-dimensional structures, out of which only one will have the biological activity. Abnormal folding of proteins may lead to prion diseases. Protein misfolding diseases are described in Chapter 52.

Chaperones help to produce the correct spatial arrangement. The word “chaperone” literally means elderly lady in charge of unmarried girls on social occasions. Chaperones attach to nascent polypeptide chains and prevent wrong foldings; so that folding is allowed only in the correct direction. They help in the assembly of tertiary and quaternary structure of proteins.

Examples of chaperones are a large family of proteins called heat shock proteins (HSPs). Any stress to the cell including heat, toxins, heavy metals, free radicals, radiation, bacteria, etc. will cause increased production of HSPs, and hence they are more correctly termed as stress proteins. Chaperonopathies are disorders resulting from "sick chaperones". These diseases progress with age.

Inhibitors of Protein Synthesis

The modern medical practice is heavily dependent on the use of antibiotics. They generally act only on bacteria and are nontoxic to human beings. This is because mammalian cells have 80S ribosomes, while bacteria have 70S ribosomes.

i. Reversible Inhibitors in Bacteria

These antibiotics are bacteriostatic. Tetracyclins bind to the 30S subunit of bacterial ribosome and so inhibit attachment of aminoacyl tRNA to the A site of ribosomes. Chloramphenicol inhibits the peptidyl transferase activity of bacterial ribosomes. Erythromycin (macrolides) and clindamycin prevent the translocation process.

ii. Irreversible Inhibitors in Bacteria

These antibiotics are bactericidal. Streptomycin and all other aminoglycoside antibiotics bind to 30S subunit of bacterial ribosomes. They cause misreading of mRNA and at high concentrations, they completely inhibit the initiation complex formation and totally inhibit protein synthesis.

iii. Inhibitors of Protein Synthesis in Mammals

They are not suitable for clinical use; but they are used as research tools. Puromycin is structurally similar to tyrosine-tRNA and gets attached to the "A" site of the ribosome. So, the incomplete peptide is released. It acts both in bacterial and mammalian cells. Cycloheximide inhibits peptidyl transferase in 60S subunit. It acts only on eukaryotic cells. Diphtheria toxin, liberated by the bacteria, Corynebacterium diptheria, causes inactivation of EF-2 by attachment of ADP to EF-2 and consequent inhibition of protein biosynthesis in mammalian systems. Inhibitors of transcription (described elsewhere in this Chapter) will also in turn inhibit translation process.

Mitochondrial DNA and RNA

1. There is a dichotomy on the mitochondrial metabolism. Some of the mitochondrial protein synthesis is under the control of mitochondrial DNA; but important proteins of the outer membrane of the mitochondria are synthesized under the influence of nuclear DNA. Table 41.5 shows that mitochondria are similar to bacteria than mammalian cells. This fact supports the theory that mitochondria are derived from prokaryotes symbiotically adapted to multicellular organisms.

2. The mitochondrial DNA (mtDNA) is circular, has about 16,500 nucleotides. The mtDNA has information for synthesis of 2 ribosomal RNAs, 22 tRNAs and 13 proteins. All of them are components of electron transport chain. However, most of mitochondrial proteins are encoded by nuclear DNA and synthesized in the cytoplasm.

3. Mitochondria require only 22 tRNAs. Mitochondrial DNA (mtDNA) replication takes about 1 hour. Other features of mitochondrial genes are:

4. Maternal inheritance: Since the mitochondria are inherited cytoplasmically, the mtDNA is inherited from the mother. Mother transmits mtDNA through oocyte.

5. There are hundreds of copies of mtDNA in each cell (nuclear DNA has only 2 copies). During cell division, mtDNA replicates and they segregate to the daughter cells. If a mutation occurs in mtDNA, the daughter cells may inherit the mutant or normal mtDNA. Heteroplasmy is defined as the presence of normal and mutant mtDNA in different proportions in different cells.

6. High mutation rate.

7. Age related accumulation of mutations in mtDNA may be responsible for age related decrease in cellular OXPHOS function, and progression of other degenerative diseases.
8. Defects in mitochondrial genome will lead to mitochondrial myopathies. Leber’s hereditary optic neuropathy is caused by a single base mutation which alters one arginine to histidine in the NADH Coenzyme Q reductase. OXPHOS (oxidative phosphorylation) diseases are shown in Table 41.6. Generally, there will be manifestations in nervous system (seizures, deafness, dementia), eyes (retinitis pigmentosa, optic atrophy, blindness, ptosis), heart (cardiomyopathy), kidneys (Fanconi’s syndrome, with loss of metabolites in urine) and skeletal muscles (myoglobinuria). Treatment is limited to management of major symptoms.

Genomics and Proteomics

- **Genome** means all the DNA contained in an organism or a cell, which includes both the chromosomes within the nucleus and the DNA in mitochondria. Thus the genome of an organism is the totality of genes making up its hereditary constitution (Box 41.4).

- **Genomics** is the study of the genome and its actions. Genomics thus involves the analysis of the full DNA sequence of the organism. **Genetics** scrutinizes the functioning and composition of the single gene where as genomics addresses working of all genes and their inter-relationships in order to identify their combined influence on the growth and development of the organism (Box 41.4).

- **Proteome** is the sum of all proteins expressed by the genome of an organism, thus involving the identification of the proteins in the body and determination of their role in physiological and pathological functions. While the genome remains largely unchanged, the proteins of a particular cell change dramatically as genes are turned on and off in response to the environment (Box 41.4).

- **Proteomics**: Directly addresses the protein complement of the genome. It has been defined as the study of protein properties (expression level, post-translational modification, interactions, etc.) on a large scale to obtain a global, integrated view of disease processes, cellular processes, and networks at the protein level. The study of all proteins by a cell type or an organism is called ‘proteomics’.

**Box 41.4. Emerging Concepts**

**Micro-RNA**

Some genes produce tiny RNAs, known as micro-RNAs or miRNA, which are about 21 to 25 bases in length. Micro-RNAs are derived from large primary transcripts through specific nucleolytic processing. Primary transcripts are produced, inside the nucleus, certain exonucleases reduce their length. They have RNA hairpin structure (showing internal hybridization to make it two strands), and are called short hairpin RNA (shRNA). These are transported through nuclear pore into cytoplasm, where out of the two strands, one is broken by dicer nuclease. The selected strand is called the guide strand, which is incorporated into the RISC (RNA induced silencing complex (RISC) to form functional silencer of mRNA. The guide strand provides specificity to RISC, which binds and then degrades complementary target mRNA in the cytoplasm. The micro-RNAs bind to matching pieces of messenger RNA, turn it into a double strand and keep it from doing its job. The process effectively blocks the production of the corresponding protein, causing translation arrest.

**Interfering RNA or RNAi or siRNA**

Andrew Fire and Craig Mello found that when double-stranded RNA was introduced into roundworms, it would silence the gene corresponding to that RNA. They were awarded Nobel prize in 2006. RNA interference is a protective mechanism against viruses, which sometimes create double-stranded RNA when they replicate. Short double-strand RNA, again about 21 to 25 bases, would silence the corresponding gene. RNAi is a faster way to turn off genes. Both RNAi and micro-RNA result in decreased levels of functional proteins in the cells. RNAi degrades the mRNA through specific cytoplasmic organelles called P bodies. (Micro-RNA reduces the translation of mRNA into protein). Scientists are aiming to use RNA interference to treat diseases, especially HIV infection.

**Antisense Therapy**

The mRNA contains a message or “sense” to be translated into protein. If an oligonucleotide chain having complementary sequence to an mRNA is made, it is said to be “antisense”. When antisense oligonucleotide (either RNA or DNA) is added, it will trap the normal mRNA and so protein biosynthesis can be stopped. This is called antisense strategy (Fig. 41.21). Small oligonucleotides (about 7 to 10 nucleotides length) can act as antisense molecules. The antisense...
nucleotides are delivered into the cells by liposome encapsulation. Clinical trials on HIV and cancer are being conducted using antisense molecules.

**Fusion Proteins**
A fusion protein is the product of a fused gene. A fusion gene is produced by removing a stop codon from the DNA sequence coding for a particular polypeptide and appending the DNA sequence coding for another protein. The product is a fusion protein. Sometimes a part of a chromosome is detached and fused with another region in the same or on another chromosome. Such chromosome translocations will also lead to formation of fusion genes and fusion proteins.
CHAPTER 42

Inheritance, Mutations and Control of Gene Expression

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Principles of heredity
2. Dominant and recessive inheritance
3. Mutations
4. Operon concept
5. Repression and de-repression
6. Prenatal diagnosis
7. Newborn screening

It is estimated that more than 6% of all infants born alive suffer from genetic diseases and 1% from chromosomal aberrations. The former conditions involve minor alterations in DNA make up, e.g. phenylketonuria. The latter ones are due to major changes in chromosomes; e.g. Down's syndrome, Turner's syndrome. Gregor Johann Mendel (1822-84), who was Abbot of Brun, described the principles of heredity in 1866. As it was printed in an obscure journal, it remained unnoticed for many years. In 1900, Hugo de Vries and C. Correns, rediscovered and confirmed Mendel's theory. Walter Flemming demonstrated chromosomes in 1882. In 1902, Walter Sutton showed that chromosomes are in pairs and are the carriers of Mendel's Unit of heredity. The word 'Gene' was coined by Wilhelm Johannsen in 1909. According to Mendel's law, if "A" represents a dominant character and "b" recessive or latent character in parents, then (A+b)² = A²+2 Ab +b², i.e. one-half of progeny will have mixed parental characters (2Ab); one-fourth will have dominant (A²) and one-fourth will have recessive (b²) characters. All genes are not equal in the eyes of evolution. Evolutionarily relevant mutations tend to accumulate in 'hotspot genes' and at specific positions within genes. Genetic evolution is constrained by gene function, the structure of genetic networks, and population biology.

Basic Principles of Heredity
1. Heredity is transmitted from parent to offspring as individual characters.

2. The genes are linearly distributed on chromosomes at fixed positions (loci).
3. Genes that may replace one another at the same locus are called allelomorphic genes or alleles. Alleles are genes responsible for alternate or contrasting characters. Usually one allele is inherited from father and the other from mother.
4. When both alleles carry the same defect, it is said to be homozygous.
5. When one allele is normal, and the counterpart is defective; it is called heterozygous.
6. Genes on the same chromosome are linked; and the linkages are more pronounced in the nearby genes.
7. The observed character expressed by the gene is called phenotype.
8. The genotype represents the set pattern of genes present in the cell.

1. Dominant Inheritance
i. It is characterized by the phenotypic expression of the disease, even if one allele is abnormal or in heterozygous state. In the example shown in Figure 42.1, the father has the defective gene, marked as D. The possible permutations of gametes are shown in the figure.
ii. Affected men and women transmit the abnormality to their children. When an affected heterozygote (Dd) marries a normal spouse (dd), half of the progeny can have the disease.
iii. Examples of diseases with autosomal dominant inheritance are chondrodystrophy (dwarfism) and some types of porphyrias.
2. Autosomal Recessive Inheritance
   
   i. Phenotype or a particular character is controlled by a pair of alleles located on a specified area on the chromosomes.
   
   ii. If the disease is manifested only in homozygous state (not expressed in heterozygous condition), it is known as recessive transmission.
   
   iii. For example, in a person suffering from sickle cell anemia, both the alleles for beta globin gene have mutated. Hence all beta globin chains will be abnormal. He is homozygous for sickle cell disease.
   
   iv. In certain cases, the carrier state may be identified biochemically, then it is referred to as the trait of the disease. For example, in sickle cell trait, one beta globin gene (allele) is normal; while the other one is abnormal (carrier state). Such individual is heterozygous to that character. Therefore, normal gene produces normal Hb and abnormal gene produces HbS. Thus inside the RBC, 50% of hemoglobin molecules are abnormal. This can be identified by electrophoresis.
   
   v. When both father and mother are carriers, one-quarter of siblings express the disease (both alleles abnormal), another one-quarter of siblings are normal, and half of the children are carriers (Fig. 42.2). This chance factor is acting on each progeny.
   
   vi. If only one parent is carrier and the other is normal; then there will be no affected child, but 50% children are carriers.
   
   vii. Most of the inborn errors of metabolism are recessively transmitted. A few examples are phenylketonuria, albinism, galactosemia and sickle cell anemia.

3. Sex-linked (X-linked) Recessive Inheritance
   
   i. In the autosomal conditions, the disease occurs in both sexes with equal frequency. But in sex-linked conditions, X-chromosome carries the abnormal gene. See Figure 42.3.
   
   ii. In a wedding between a normal male and a carrier female, the probabilities are that one-quarter is male with disease; one-quarter is female carrier; one-quarter normal male and one-quarter normal female.
   
   iii. If an affected male marries a normal female, male children will be normal, but all female children will be carriers, because they all inherit the abnormal X from their father (Fig. 42.3).
   
   iv. In X-linked recessive condition, normal X dominates over abnormal X; but abnormal X is expressed when present with Y.
   
   v. Hemophilia, glucose-6-phosphate dehydrogenase deficiency, pseudo-hypertrophic muscular dystrophy (Duchenne type), and red green color blindness are examples of sex-linked recessive inheritance.

Population Genetics
A law stating the frequency of abnormal genes in population was discovered in 1908 independently by Hardy (mathematician) and Weinberg (physician). The **Hardy-Weinberg law** states that, if there are \( p \) gametes of 'A' type and \( q \) gametes of 'a' type and when \( p + q = 1 \) in one generation, the genotypes and their frequency will be:
Fig. 42.3. Sex-linked recessive inheritance

<table>
<thead>
<tr>
<th>Genotype</th>
<th>AA</th>
<th>Aa</th>
<th>aa</th>
</tr>
</thead>
<tbody>
<tr>
<td>relative frequency</td>
<td>(p^2)</td>
<td>(2pq)</td>
<td>(q^2)</td>
</tr>
</tbody>
</table>

The law states that \((p^2 + 2pq + q^2) = 1\) and the genotypes in the population from one generation to another generation will be in equilibrium. Or, \(p^2 : 2pq : q^2\) ratio is maintained in all generations (the ratio of normal and abnormal gene is maintained in all generations). This law is useful to calculate the frequency of a harmful gene in a population. It is known that 1 in 20,000 live births is an albino, which is inherited recessively. Let us say, they are ‘aa’ genotypes. Thus the remaining 19,999 are ‘AA’ or ‘Aa’ genotypes. The frequency of q of the recessive albino gene can be calculated as follows: \(q^2 = 1/20,000\). Therefore \(q = 1/141\). Since \(p + q = 1\), in this particular example, \(p = 140/141\). Therefore the ‘Aa’ genotype, or \(2pq = 1/70\). Thus 1 out of 70 individuals, carries the abnormal gene for albinism. In other words, 1.4% of all persons are heterozygous for albino allele. So, there are 280 carriers for each albino patient.

Spontaneous Mutations
The abnormal genes are produced by natural mutations and deleted by Darwin’s natural selection mechanism, e.g. phenylketonuria patient is mentally retarded and therefore lesser chances to procure a child. The law essentially states that the rate of new mutation equals the elimination. That means, spontaneous mutation is taking place on that gene in successive generations.

Law of Selection Applied to Genes
However, an abnormal gene need not always be eliminated from a population, if there is a selective advantage for heterozygous state. The best example is the sickle-cell anemia trait. The geographical distribution of sickle-cell anemia fairly well overlaps with malaria endemicity. Sickle-cell anemia is a lethal disease; patient dies before the reproductive age, and therefore the gene must have been eliminated. But the heterozygous persons carry RBCs having 50% normal Hb and 50% abnormal hemoglobin. So, the oxygen pressure inside the RBC is lesser than normal individuals. Hence, malarial parasites do not multiply easily in heterozygous individuals (Chapter 22). Therefore, in the malarial endemic areas, the lethal nature of the gene in the homozygous state is counter-balanced by the advantage in heterozygous state. This is called balanced polymorphism. Genes for thalassemia, GPD deficiency, etc. are also maintained in the population by such a mechanism.

Marriages with Close-cousins are Inadvisable
The probability of two carriers getting married is increased in consanguinous marriages. (Latin, con = with; sanguis = blood). So, there is increased frequency of genetic diseases in their children. For example, phenylketonuria has an incidence of 1 in 25,000 in general population; but it is 13 / 25,000 in children of first cousin marriages.

Cytoplasmic Inheritance
This follows a maternal line of transmission, e.g. mitochondrial inheritance. Transmission of mitochondrial genes ends with each son, because son does not pass the mitochondrial genes to his offspring. Mothers are heteroplasmic and are therefore unaffected, e.g. Leber’s optic neuropathy (Table 41.6), myoclonic epilepsy, etc.

Chromosomal Recombination
During meiosis (reduction division), exchange of genetic information between homologous chromosomes is taking place. Homologous chromosomes are exactly aligned so that respective genes oppose. Then a process of crossover occurs, so that reciprocal exchange of genetic information is obtained. Such a recombination can explain the fact that the

Genetic Disorders

The locations of many genes have been identified on specific chromosomes. A small selected list is given in Table 42.1. Genetic disorders are of different types:

A. Chromosomal disorders. These are identified by karyotyping, e.g. 21 trisomy.

B. Single gene defect, sometimes identified by biochemical methods, e.g. phenylketonuria.

C. Mitochondrial abnormalities.

D. Multifactorial disorders.

Treatment Policies of Genetic Diseases

1. Replace the end-product of the missing enzyme, e.g. administer thyroxine in familial goitre.

2. Limit the substrate of the missing enzyme. In phenylketonuria, reduce phenyl alanine in diet. In galactosemia remove lactose from diet.

3. Replace missing protein, e.g. administer AHG (anti-hemophilic globulin) in hemophilia.

4. Activity of abnormal enzyme is enhanced, e.g. large quantities of vitamin B12 is useful in methyl malonic aciduria.

5. Induction of enzyme; in Crigler-Najjar syndrome, glucuronyl transferase enzyme can be induced by phenobarbitone.

6. Gene therapy is still in experimental stages, but may become common in the next generation.

MUTATIONS

i. A mutation is defined as a change in nucleotide sequence of DNA. This may be either gross, so that large areas of chromosome are changed, or may be subtle with a change in one or a few nucleotides.

ii. Mutation may be defined as an abrupt spontaneous origin of new character.

iii. Statistically, out of every 10^6 cell divisions, one mutation takes place.

1. Classification of Mutations

A point mutation is defined as change in a single nucleotide. This may be subclassified as (a) substitution, (b) deletion, and (c) insertion. All of them may lead to mis-sense, nonsense or frameshift effects.

1-A. Substitution

Replacement of a purine by another purine (A to G or G to A) or pyrimidine by pyrimidine (T to C or C to T) is called Transition mutation. If a purine is changed to a pyrimidine (e.g. A to C) or a pyrimidine to a purine (e.g. T to G), it is called a transversion. The point mutation present in DNA is transcribed
and translated, so that the defective gene produces an abnormal protein.

1-B. Deletion
Deletions may be subclassified into—
- **i. Large gene deletions**, e.g. alpha thalassemia (entire gene) or hemophilia (partial)
- **ii. Deletion of a codon**, e.g. cystic fibrosis (one amino acid, 508th phenyl alanine is missing in the CFTR protein).
- **iii. Deletion of a single base**, which will give rise to frameshift effect.

1-C. Insertion
Insertions or additions or expansions are subclassified into—
- **i. Single base additions**, leading to frameshift effect.
- **ii. Trinucleotide expansions**. In Huntington's chorea, CAG trinucleotides are repeated 30 to 300 times. This leads to a polyglutamine repeat in the protein. The severity of the disease is increased as the numbers of repeats are more.
- **iii. Duplications**. In Duchenne Muscular Dystrophy (DMD) gene is duplicated in the disease.

2. Effects of Mutations
2-A. Silent Mutation
A point mutation may change the codon for one amino acid to a synonym for the same amino acid. Then the mutation is silent and has no effect on the phenotype. For example, CUA is mutated to CUC; both code for leucine, and so this mutation has no effect.

2-B. Mis-sense but Acceptable Mutation
A change in amino acid may be produced in the protein; but with no functional consequences. For example, in the normal hemoglobin A molecule, the 67th amino acid in beta chain (HbA \(\beta-67\)) is valine. The codon in mRNA is GUU. If a point mutation changes it to GCU, the amino acid becomes alanine; this is called \(\text{Hb Sydney}\). This variant is functionally normal. A **conserved mutation** occurs when the altered amino acid has the same properties of the original one; e.g. Glutamic acid to Aspartic acid.

2-C. Mis-sense; Partially Acceptable Mutation
In this type, the amino acid substitution affects the functional properties of the protein. \(\text{HbS}\) or sickle-cell hemoglobin is produced by a mutation of the beta chain in which the 6th position is changed to valine, instead of the normal glutamate. Here, the normal codon GAG is changed to GUG (**transversion**). \(\text{HbS}\) has abnormal electrophoretic mobility and subnormal function, leading to sickle-cell anemia. Details are given in Chapter 22.

2-D. Mis-sense; Unacceptable Mutation
The single amino acid substitution alters the properties of the protein to such an extent that it becomes nonfunctional and the condition is incompatible with normal life. For example, \(\text{HbM}\) results from histidine to tyrosine substitution (CAU to UAU) of the distal histidine residue of alpha chain. There is met-hemoglobinemia.

2-E. Nonsense; Terminator Codon Mutation
A tyrosine (codon, UAC) may be mutated to a termination codon (UAA or UAG). This leads to premature termination of the protein, and so functional activity may be destroyed, e.g. beta-thalassemia. Or, a terminator codon is altered into a coding codon (UAA to CAA). This results in elongation of the protein to produce "run on polypeptide" (Hb Constant spring) (Chapter 22).

2-F. Frameshift Mutation
This is due to addition or deletion of bases. From that point onwards, the reading frame shifts. A "garbled" (completely irrelevant) protein, with altered amino acid sequence is produced. An example:

<table>
<thead>
<tr>
<th>Normal mRNA</th>
<th>AUG UCU UGC AAA......</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal protein</td>
<td>Met Ser Cys Lys.......</td>
</tr>
<tr>
<td>DeletedU mRNA</td>
<td>AUG CUU GCA AA.......</td>
</tr>
<tr>
<td>Garbled protein</td>
<td>Met Leu Ala .............</td>
</tr>
</tbody>
</table>

In this hypothetical example, deletion of one uracil changes all the triplet codons thereafter. Therefore, a useless protein or no protein is produced. Frame shift mutation can lead to thalassemia due to premature chain termination and run-on-polypeptide that are non-functional.

2-G. Conditional Mutations
Most of the spontaneous mutations are **conditional**; they are manifested only when circumstances are appropriate. Bacteria acquire resistance, if treated with antibiotics for a long time. This is explained by spontaneous conditional mutations. In the normal
circumstances, wild bacilli will grow. In the medium containing antibiotic, the resistant bacilli are selected. In a tuberculous patient, a lung cavity may harbor about $10^{12}$ bacilli. This may contain about $10^6$ mutations, out of which a few could be streptomycin resistant. Therefore if only one drug is given, there will be overgrowth of drug resistant bacilli. To avoid this, a combination of two anti-tuberculous drugs is given. So, drug-1-resistant mutants are killed by drug-2 and drug-2-resistant mutants are removed by drug-1. The statistical probability of a single bacillus acquiring resistance against both drugs is negligible.

3. Mutagens and Mutagenesis

Any agent which will increase DNA damage or cell proliferation can cause increased rate of mutations also. Such substances are called mutagens. X-ray, gamma-ray, UV ray, acridine orange, etc. are well known mutagens. Muller (Nobel Prize, 1946) showed that the rate of mutation was proportional to the dose of irradiation. Beadle (Nobel Prize, 1958) showed that the effect of X-irradiation on metabolism was due to mutations of genes. Tatum (Nobel Prize, 1958) further showed that a mutation of a single gene resulted only in a single chemical reaction, which gave evidence to the concept of "one gene, one enzyme".

4. Manifestations of Mutations

4-A. Lethal Mutations

The alteration is incompatible with life of the cell or the organism. For example, mutation producing alpha-4 Hb is lethal, and so the embryo dies.

4-B. Silent Mutations

Alteration at an insignificant region of a protein may not have any functional effect.

4-C. Beneficial Mutations

Although rare, beneficial spontaneous mutations are the basis of evolution. Such beneficial mutants are artificially selected in agriculture. Normal maize is deficient in tryptophan. Tryptophan-rich maize varieties are now available for cultivation. Micro-organisms often have antigenic mutation. These are beneficial to micro-organisms (but of course, bad to human beings).

4-D. Carcinogenic Effect

The mutation may not be lethal, but may alter the regulatory mechanisms. Such a mutation in a somatic cell may result in uncontrolled cell division leading to cancer. Any substance causing increased rate of mutation can also increase the probability of cancer. Thus all carcinogens are mutagens.

Ame's Test to Detect Mutagenicity

Special strains of *Salmonella typhimurium* (bacteria causing typhoid) are selected. They have the mutated histidine gene. They will grow only when histidine is provided in the culture medium. They are sensitive to mutagens because they are defective in excision repair system for correcting DNA damage. The compound to be tested is mixed with bacteria and introduced into histidine-deficient medium. All bacteria will die, except those who have reverted back to wild type and acquire the capacity to synthesize histidine. This is called reverse mutation. The number of colonies will be proportional to the quantity of mutagen.

Site-directed Mutagenesis

Michael Smith (Nobel Prize, 1993) described this technique. An oligo-deoxy-ribonucleotide is synthesized, whose sequence is complementary to a part of a known gene. A specific deletion/insertion is produced in the oligonucleotide. It is then extended by DNAP. After replication, one strand is normal and the other strand contains the mutation at the specific site. This allows study on the effect of that particular mutation.

CELL CYCLE

i. The term cell cycle refers to the events occurring during the period between two mitotic divisions. It is divided into G1 (gap-1), S (synthesis), G2 (gap-2), and M (mitosis) phases.

ii. The cell division is taking place in M phase. It is the shortest phase, lasting about 1 hour. The daughter cells then either enter into Go (undividing or dormant) phase or re-enter the cell cycle when there is necessity for growth and repair.

iii. In a normal cell population, most of the cells are in Go phase. General metabolic events are taking place in Go phase.

iv. Interphase is the period between the end of M phase and the beginning of the next mitosis.

v. In G1 phase, protein and RNA contents increase. Duration of G1 phase is about 12 hours.
vi. In the S phase, DNA is synthesized, but only once. DNA content doubles, nucleus becomes tetraploid (4n). The entire diploid genome is replicated into a tetraploid genome. S phase lasts about 6 to 8 hours.

vii. In the G2 phase, there is cytoplasmic enlargement. DNA repair is also taking place in the G2 phase. Proteins, especially histones are also produced. It lasts for about 4 to 5 hours. The total cell cycle is about 20-22 hours duration in mammalian cells (Fig. 42.4).

Cell Cycle Controls or Check Points
Hartwell, Hunt and Nurse were awarded Nobel Prize in 2001 for their contributions in elucidating the cell cycle regulation. The important checks occur in 3 stages; at G1-S transition, during S phase or at G2-M boundary. Of this G1 phase check point is more complex and is under strict control. Four types of cyclins (A, B, D and E) and 5 different cyclin dependent kinases (CDK 1, 2, 4, 5 and 6) control the cycle. Cyclins are so named because they are synthesized throughout the cell cycle, and are abruptly destroyed during mitosis. Cyclins activate CDKs which phosphorylate specific substrates (regulatory proteins). Mammalian cells in Go phase are stimulated by growth factors, which trigger them to enter into G1 phase (Fig. 42.4). For the discovery of growth factors, Stanley Cohen and Rita Levi-Montalcini were awarded Nobel Prize in 1986.

ATM is a protein kinase, which is associated with the DNA. If a break in DNA is produced (e.g. UV light), the ATM is dissociated, activated, and then initiates a series of cascade reaction. A simplified version is shown in Figure 42.4. CDK2-cyclin E complex directs the cells in G1 phase to enter into S phase. CDK2 complexed with cyclin A pushes forward the cells to complete the S phase. Then, CDK2, cyclin A and B make the cells complete the G2 phase and enter into the M phase (Fig. 42.4).

The MPF (M phase promoting factor) pushes the cell into mitosis. MPF has two subunits; p34 and p45; the number indicating molecular weight in kD. At the end of G2, p34 is activated by dephosphorylation, which phosphorylates many substrates, including histones (leading to chromosome condensation in M phase) and lamins (causing nuclear envelope breakdown). By the end of M phase the MPF...
becomes inactive by cyclin degradation. The action of many oncogenes (Chapter 51) and growth factors are explained by cyclin-cyclin kinase system. For example, the bcl oncogene, associated with B cell lymphoma, is the gene for cyclin D.

Cell cycle arrest mediated by a checkpoint may fail for a variety of reasons. First, like all cellular processes, checkpoints have an intrinsic error rate. Second, after a period of arrest, even though damage remains unrepaired, the cell may resume the cycle. Third, check points may be mutated, leading to unchecked growth, leading to cancer. If damage is not repaired and the cell passes to the next stage, secondary lesions result. For example, if a G1 cell with single stranded breaks in DNA progresses through S phase, these are converted into double stranded breaks. Segregation of broken chromosomes may lead to loss of certain fragments during M phase.

**Retinoblastoma (RB) Oncosuppressor Protein**

Rb protein is the product of an oncosuppressor gene (Chapter 51). It is so named, because it was isolated from patients of retinoblastoma (cancer arising from retina). It is a cell cycle regulator. It binds and inactivates the E2F, a transcription factor. Thus Rb inhibits cell cycle at G1 phase. But in controlled cell cycles, cyclin D levels rise in the late G1 phase. The cyclin D inactivates Rb, which is separated from E2F. This is the normal mechanism to overcome the G1 arrest by Rb. Certain tumor antigens derived from viruses such as SV40, HSV, HPV may combine with Rb. Then, Rb cannot inhibit cell cycle, leading to continuous cell division and cancer (Fig. 42.5).

**The p53 Oncosuppressor Protein**

It is so named because it is a protein with 53 kD in size. It has 393 amino acids. Its half-life is only 5-10 minutes. It inhibits cell division, allowing them to repair. If damage is extensive and repair is not possible, the p53 directs the cell to apoptosis. PCNA gene encodes a nuclear protein that is a cofactor for DNA polymerase. The p53 downregulates PCNA transcription, blocks the DNA polymerase and causes arrest in G1. It is phosphorylated in a cell cycle dependent manner by CDK4. Maximum level of p53 phosphorylation is reached during mitosis.

**Embryonic Development**

Edward Lewis, Christiane Nusslein-Volhard and Eric Wieschaus have been awarded Nobel Prize in 1995 for their discoveries on genetic control of early embryonic development. They identified and classified the genes determining the body axis and separate organs. These genes are called homeotic genes in drosophilia and HOX genes in mammals.

**Apoptosis (Programmed Cell Death)**

Differentiation and growth needs reshaping of organs; this could be done only when old cells are removed from the area. Removal of superfluous, aged or partially damaged cell is done by apoptosis. The term literally means "dropping off", similar to the old leaf falling from the tree. Nuclear shrinkage, chromatin condensation, membrane blebbing and step-ladder pattern of DNA in electrophoresis are characteristic features of apoptosis (Fig. 42.6A). Apoptosis-mediating genes (suicidal genes) (oncosuppressor genes) are c-fos, p53, Rb. Apoptosis-protecting genes are bcl-2 and other oncogenes. Stress and other stimuli activate certain cell surface receptors, and a cascade of activation takes place. The final effector mechanism of cell death is through the activation of caspases. Brenner, Horvitz and Sulston were awarded Nobel Prize in 2002 for their contributions in apoptosis mechanisms.
Mitochondrial Permeability Transition Pore (MPTP)
MPTP is located between the inner and outer mitochondrial membrane. It is made up of voltage dependent anion channel (VDAC) located in the outer membrane, adenine nucleotide translocase (ANT) located in the inner membrane and cyclophilin-D. The pore is normally in the closed state. It is opened under oxidative stress or attack of free radicals. This causes increased matrix calcium ions. Opening of the pore results in an increase in the permeability of the mitochondrial membrane (Chapter 19) to molecules weighing less than 1500 Daltons. This leads to mitochondrial swelling and cell death. Opening of the MPT pore causes ATP depletion and release of cytochrome c; the latter acts as a trigger for apoptosis. Reactive oxygen species (Chapter 20) cause opening of MPTP, which leads to apoptosis.

Caspase Activation Cascade
CASPASE is the acronym for "Cysteinyl aspartate specific protease". They are proteases with cysteine in their active center. Caspases 1 to 10 are identified; they are named in the order of their discovery. All these enzymes are secreted as inactive zymogen form; they are activated one by one. The caspase 8 is the first one activated, which is otherwise called the initiator. The final one is caspase 3, the executor of death, which is officially named as "Yama", the Hindu God of Death. Caspase 3 will hydrolyze certain target proteins, like those maintaining cytoskeleton. Cytochrome c, when released from mitochondria into cytosol activates procaspase 9 to caspase 9. This causes activation of the whole pathway (Fig. 42.6B).

REGULATION OF GENE EXPRESSION
1. Induction and Repression
   i. Pioneer in genetic studies, Ochoa was awarded Nobel Prize in 1959. Synthesis of proteins under the influence of gene is called gene expression. All genes of the cell are not expressed at all the time. For example, the insulin gene is expressed only in the beta cells of pancreas; but not in other tissues. In other words, insulin gene is in the state of repression in all other cells.
   ii. Some genes are expressed almost always in all cells. For example, enzymes of glycolysis are synthesized by all cells. Such genes are called constitutive genes or housekeeping genes.
   iii. The same gene may be alternatively opened and shut, as per the need of the metabolism. Such regulation is done by induction and repression mechanisms.
   iv. Induction is the phenomenon of increased synthesis of protein or enzyme in response to certain signal. Such enzymes are said to be inducible; and the signals are called inducers.
   v. Induction is turning "on" the switch of the gene. Repression is turning "off" the gene expression.

2. Operon Concept of Gene Regulation
Francois Jacob and Jacques Monod put forward the operon concept in 1961, for which they were awarded Nobel Prize in 1965. Andre Lwoff who worked on the derepression also received the Nobel Prize in 1965. Jacob and Monod theory was based on the observations on lactose metabolism in Escherichia coli (bacteria). Cells grown in glucose medium do not contain beta galactosidase (lactase). But when cells are transferred to a medium containing only lactose, then the enzyme level in the cell increases several thousand fold. Thus, lactose metabolism is regulated by an induction or derepression process.

The Lac Operon
   i. Operon is a unit of gene expression; it includes structural genes, control elements, regulator/inhibitor gene, promoter and operator areas.
   ii. In the bacterial cell, the Z gene encodes beta-galactosidase, the enzyme which hydrolyzes lactose to galactose and glucose.
   iii. The Y gene is responsible for production of a permease which transports lactose and galactose into the cell. The A gene codes for thiogalactoside transacetylase.
   iv. Since Z, Y and A code for the structure of the proteins, they are called structural genes. These 3 genes are present as contiguous segments of DNA (Fig. 42.7).
   v. The transcription of these genes start from a common promoter (P), located close to the Z gene. The RNA polymerase binds to the promoter and transcribes these 3 structural genes as a single mRNA.

A. Transcription is Normally Repressed
   i. Transcription of the structural gene is under the control of another regulator or the "i" (inhibitor) gene. It is far away from the structural genes.
   ii. Regulatory gene produces a repressor molecule. The lac repressor has a molecular weight of 150 kD.
iii. The lac repressor has strong affinity to the operator site. The operator region is 27 bp long, to which the repressor tightly binds. The operator site is between the promoter and structural genes (Fig. 42.7A).

iv. When RNAP identifies the promoter sequence and moves towards the structural genes, it is stopped by the hindrance produced by repressor molecule. This is like the action of a zip. If a thread is placed across its way, the zip cannot move further. Similarly, when repressor is attached to the operator, RNAP cannot move further. So structural genes are not transcribed.

v. Thus, when lactose is not available, the lactose utilizing enzymes are not synthesized (Fig. 42.7A).

B. Derepression of Lac Operon
i. When lactose is introduced into the medium, lactose binds to the repressor protein; one molecule on each subunit (Fig. 42.7B).

ii. Repressor-lactose complex is inactive, which does not bind to the operator region. So there is no repressor molecule at the operator site.

iii. Now, RNAP can transcribe the structural genes, which are then translated (Fig. 42.7B).

iv. Thus lactose switches the genes "on". Lactose induces the synthesis of lactose utilizing enzymes. Hence lactose is an inducer of these genes and the mechanism is said to be derepression of the gene. Such regulation, where several proteins are regulated as one unit, is termed as coordinate gene regulation.

C. Fine-regulation of Lac Operon
When the culture medium contains both glucose and lactose, the bacteria preferentially utilize glucose. Only when glucose is exhausted, lactose is metabolized. Thus lac operon is induced by lactose only when glucose is not available. It was thought that the repression of lac operon is by some catabolite of glucose; hence this was called catabolite repression. This is now known to be mediated by the catabolite activator protein (CAP). The RNA polymerase can attach to promoter site, only when CAP combined with cyclic AMP (cAMP) is available. CAP-CAMP regulator is acting as a positive regulator. It is necessary for gene expression. Bacteria accumulate cAMP only when starved. When glucose is exhausted, cAMP is available in plenty and so CAP-cAMP complex is formed. Then RNAP can identify the promoter site. Thus lac operon is controlled by two factors; one that acts positively through CAP-cAMP complex, and the second one acts negatively through Lac repressor that antagonizes binding of RNA polymerase to the promoter.

In case of mutation in lac operon, and the product is not able to bind the operator site, there will be constitutive expression of lac gene. Or, mutations in the lac operator region will not allow binding of normal repressor molecule; leading again to constitutive expression of lac gene.

D. Clinical Applications
Lactase in human intestine is an inducible enzyme. Clinical manifestations of lactase deficiency and
lactose intolerance are described in Chapter 9. In humans, examples of derepression include induction of tryptophan pyrrolase, and transaminases by glucocorticoids; as well as ALA synthase by barbiturates.

Regulation of Genes by Repression

i. Repression is the mechanism by which the presence of excess product of a pathway shuts off the synthesis of the key enzyme of that pathway.

ii. Heme synthesis is an example. It is regulated by repression of ALA synthase, the key enzyme of the pathway (Chapter 21). Transcription of structural gene for ALA synthase is controlled by a regulatory gene. It produces the apo-repressor, which binds with heme and becomes the active holo-repressor. Here, heme acts as the co-repressor (Fig. 42.8).

iii. The holo-repressor binds to the operator and stops transcription of the gene. Upstream to the structural genes lies the promoter site, where the RNA-polymerase (RNAP) attaches and starts mRNA synthesis. The operator site is in between promoter and structural genes. So when RNAP reaches operator site, it cannot move further (Fig. 42.8). So enzyme synthesis stops, and heme synthesis slows down.

iv. On the other hand, when heme is not available, co-repressor is not available, therefore, repression is not effective and enzyme synthesis starts. Thus, the synthesis of heme is autoregulated by the repression mechanism.

v. Thalassemia is a condition when normal hemoglobins are produced in abnormal ratios (Chapter 22). When alpha chain synthesis is blocked due to a mutation on the promoter, there is compensatory increase in beta chain synthesis. Instead of the $\alpha_2 \beta_2$ combination for normal hemoglobin, an abnormal $\beta_4$ combination results.

Hormone Response Elements (HRE)

In higher organisms, hormones or their second messengers function as inducers. Many hormones, particularly steroid hormones, elicit physiological response through controlling gene expression (Fig. 42.9). Glucocorticoids attach to a cytoplasmic receptor; then the receptor-hormone complex translocates to the nucleus. It finally attaches on the HRE in the DNA. The receptor binds at the enhancer region, which activates the promoter, so that transcription is accelerated. Examples are receptors for glucocorticoid, mineralocorticoid, progesterone, androgen, estrogen, thyroxine, vitamin D and retinoic acid.
**Hormone-receptor superfamily** includes receptors for glucocorticoid, mineralocorticoid, progesterone, androgen, estrogen, thyroxin, vitamin D, retinoic acid and erb oncogene protein. All these receptors have a conserved DNA-binding region in the middle and a conserved C-terminal hormone-binding site. When hormone binds, the receptor molecule becomes dimerized, which then specifically binds the HRE region of the DNA (Table 44.2).

**Gene Amplification**
This is a mechanism by which gene expression is increased thousand-fold. In Drosophilia (fruit fly), during oogenesis, an amplification of a few genes of egg shell protein occurs. This is generated by a process of repeated initiation of DNA synthesis. In electron microscopy, it is seen as a big replication bubble.

Such a mechanism is operating in human beings also. Methotrexate is a widely used anticancer drug, which acts by inhibiting dihydrofolate reductase (Chapter 39). In patients receiving methotrexate for a long time, the malignant cells are seen to develop drug resistance by increasing the number of genes for dihydrofolate reductase by gene amplification. Oncogenes are also shown to be amplified in many cancer cells.

**Gene Switching**
Sometimes, one gene is switched off while a closely related gene takes up its function. A good example is the hemoglobin synthesis. In embryo, hemoglobin is made up of 2 zeta and 2 epsilon chains. By the 6th month of intrauterine life, this is changed to HbF, consisting of alpha 2-gamma 2 chains. After birth, HbF is replaced by adult types of Hb, 97% HbA1 (alpha 2-beta 2 chains) and 3% HbA2 (alpha 2-delta 2 composition) (Chapter 22). Thus the gene expression is switched from epsilon-zeta to alpha-gamma and later to alpha-beta or alpha-delta.

Another example of gene switching is seen in the immunoglobulin (Ig) synthesis. During the primary immune response, IgM antibodies are produced. In the secondary immune response, IgG antibodies are seen. Thus switching of gene from IgM to IgG is taking place (Chapter 49). Somatic recombination is described in Chapter 49.

**VIRUSES**
Viruses are absolute parasites on living cells. They contain only the bare minimum of genetic information for survival and replication. Salvador Luria in 1942 showed that viruses are visible only by electron microscopy. Alfred Hershey proved that nucleic acids, but not proteins, are the genetic material in viruses. Both got Nobel Prize in 1969. Viruses generally bind to specific receptors on the host cell surface (Fig. 42.10). Binding of viruses involve specialized microdomains on the host cell membranes, the lipid rafts and the glycans. For example, binding of HIV to CD4 receptor occurs in lipid raft areas through GP120 (glycoprotein of the virus). Influenza virus binds NANA (N-acetyl neuraminic acid) residues on glycoprotein receptors on cell surface through hemagglutinin (H). The neuraminidase (N) present in the virus plays an important role in budding of new virions. There are 16 types of H and 9 types of N antigens that make the different strains of influenza virus. For example, avian flu virus has H5N1, and swine flu virus has H1N1 antigens. After entry into the host cell, the viruses utilize the host cell machinery for growth and replication.

![Fig. 42.10. Life cycle of viruses in general. The numbers show the site of action of antiviral drugs mentioned in the text. 1= virus entry through receptor; 2= uncoating; 3= DNA synthesis; 4= RNA synthesis; 5= late protein synthesis; 6= packaging or assembly of new daughter viruses](image-url)
Antiviral Agents
Usual antibiotics will not affect the replication of viruses. There are only a handful of antiviral drugs available, when compared to the vast array of antibacterial agents. This is because viruses are intracellular and secondly the virus utilizes the host cell machinery for its replication. They act at different steps of the virus cycle (Fig. 42.10).

Site 1: Adsorption and penetration of virus into host cell is inhibited by antibodies, either passive or active. Neuraminidase inhibitors can be used in the treatment of influenza virus infections, e.g., Oseltamivir (Tamiflu) and Zanamivir. Mutations in the virus at the neuraminidase binding site can lead to resistance to the drug.

Site 2: Uncoating of viral nucleic acid is prevented by amantadine. It is used in treatment and prophylaxis of influenza virus.

Site 3: Synthesis of DNA is inhibited by purine or pyrimidine analogues. Acyclovir is an analogue of Guanosine. It was developed by Gertrude Elion and George Hitchings, who were awarded Nobel Prize in 1988. In the host cell, it is first phosphorylated by the virus-specific thymidine kinase; then triphosphate form is produced by the cellular enzymes. The resulting nucleotide inhibits the viral DNA polymerase. This explains the high selectivity against the virus. Iodo-deoxyuridine is the first antiviral drug marketed. It is used for topical application. Ribavirin is a guanosine analogue. It inhibits capping of viral mRNA. It is useful against respiratory syncytial virus and viral hemorrhagic fever.

Site 4: Synthesis of RNA is abolished by inhibitors of reverse transcriptase. Zidovudine is a deoxy thymidine analogue. It is useful against HIV infection. Didanosine (di- deoxy inosine) also inhibits reverse transcriptase and is used in HIV infection.

Site 5: Late protein synthesis is controlled by protease inhibitors, such as Ritonavir, Saquinavir and Indinavir. They are used against HIV infection.

Identification of Virus Infection in Host
Virus infection in patients is generally identified by demonstration of specific antibodies in the serum or by detection of virus in the host cells or fluids. Most viruses are grown in tissue culture cells. For example, Herpes simplex virus, if introduced into a culture of Vero cell line (monkey kidney cells), the virus produces lysis of cells. This is called cytopathic effect. Viruses were first grown in tissue culture by John Enders (Polioymyelitis), Frederick Robbins (Herpes simplex virus) and Thomas Weller (Varicella virus); all the three were awarded Nobel Prize in 1954.

Lytic Cycle and Lysogeny
Normally virus is replicated inside the cell, then the new virus particles get out from the cell. Most often the host cell is lysed during this process. This is called lytic cycle. Instead of the lytic process, some viruses remain dormant for months or years inside the host cells. Herpes simplex virus (HSV) and Varicella Zoster virus are examples of dormant viruses in human cells producing recurrent manifestations. Sometimes the whole virus, or certain parts of virus may be integrated into the cellular DNA, this may lead to malignant transformation (Chapter 51).

Viruses infecting bacteria are called bacteriophages. The lambda phage is a DNA virus. It enters the host bacteria, multiplied quickly, then the host cell is lysed and free viral particles come out, to infect neighboring cells. This is the lytic cycle. Instead, under certain conditions, virus enters in the lysogenic pathway. Viral DNA becomes integrated into the bacterial DNA, and replicates as a part of host DNA. This stage is called dormancy of virus or prophage. This dormancy can be "induced" or "activated" by UV irradiation, iodo-deoxyuridine, etc. which damages DNA. This switch from dormant phase to lytic infection is as follows:

In the lambda DNA, there is the OR (operator right) gene. When the repressor gene is in "on", the Cro gene is off. OR1 region is the Cro promoter and OR3 is the repressor. In the dormant state, RNAP (RNA polymerase) can fix on OR3 region and repressor gene is transcribed. The repressor protein is synthesized, which binds on the OR1 region. Therefore, Cro promoter is blocked (Fig. 42.11, upper part).

Under UV irradiation, fragments of single stranded DNA are generated. These activate another bacterial gene, recA, which produces a specific protease. This protease hydrolyzes the lambda repressor protein. Now OR2 and OR1 are free. The RNAP starts transcribing Cro gene. The Cro protein now binds OR3. Thus the repressor gene is turned "off", so that all other lambda genes are turned "on". The lytic cycle ensues (Fig. 42.11, lower part).

Transduction Process
Occasionally, the virus carries a portion of host DNA. Subsequent infection of a new host by such a virus may introduce new genes to the new host. This is called viral transduction. This process was studied by Joshua Lederberg (Nobel Prize 1958) and Max Delbruck (Nobel Prize 1969). This can be considered as genetic engineering by nature, or horizontal transmission of genes.
Viruses as Jumping Genes
Viruses may be considered as genes escaped from the existing cells of a lower evolutionary scale; they are jumping genes (see also oncogenes and viral integration in Chapter 51). The advantage imparted by virus may be the transfer of genes horizontally. Fossil records show that exoskeleton appeared in different species more or less simultaneously. About 160 million years ago, ammonites with exoskeletons appeared all over the world. These organisms are very slow moving; but the gene moved rapidly throughout the world. It may be that the gene for alkaline phosphatase has originated in few organisms, which was then transferred horizontally within a short period of paleobiology. Thus, evolutionary process is accelerated by viruses. In that case, cancer is the deferred payment by the individual for the benefit availed by the species as a whole.

Epigenetic Modifications
This is a mechanism that results in stable propagation of gene activity states from one generation of cells to the next. The epigenetic modifications include changes in histones and DNA methylation. Epigenetic states can be modified by environmental factors which may result in the expression of abnormal phenotypes. These epigenetic modifications control gene expression and changes are also inherited.

Genetic code is comparable to writing in indelible ink using the sequence of 4 nucleotides. This information is normally transferred from generation to generation with high fidelity. Information provided by epigenome is like a code written in pencil which can be erased and rewritten. The epigenome is represented by methyl groups attached to DNA base cytosine and certain covalent modifications in histones. Unlike genetic information that distinguishes one person from another (molecular fingerprint) the epigenome distinguishes one cell type from another. Any mistakes that occur (epimutations) can be erased in the same germ line. However, at times pencil writing leaves smudges even after erasing, similarly, the epimutations may be transmitted to the next generation. But all the offspring are not affected and even affected persons may not transmit the defect to their progeny, since the genetic imprints are erased and rewritten. Epigenetic modifications referred to as genomic imprinting occurs very early in the embryo.

Certain reagents will not produce any effect on the DNA sequence; but the expression of a gene (protein structure) may be altered. For example, methylation of controlling elements in DNA leads to selective silencing of genes. This will explain genomic imprinting. In Prader Willi Syndrome, a mutant gene is derived from father and in Angelman syndrome, the mutant gene is from mother. In some other cases, mutation produces an abnormal protein, which is non-functional; but interferes with the functions of a normal gene of a normal allele. For example, in Osteogenesis Imperfecta type I, the abnormal protein interferes with normal triple helix formation of collagen. This is a dominant negative effect. Transcription factors play a crucial role in eukaryotic gene expression. Epigenetic modification of core histones (acetylation of specific lysine residues) facilitates an open structure and permits access to transcription factors for interaction with DNA. On the other hand, methylation at the CG sequence of the promoters transcriptionally inactivates chromatin.

Methylation occurs naturally on cytosine bases at CpG sequences and is involved in controlling the correct expression of genes. DNA methylation is usually associated with triggering histone deacetylation, chromatin condensation, and gene silencing. Differentially methylated cytosines give rise to distinct patterns specific for each tissue type and disease state. Such methylation-variable positions (MVPs) are not uniformly distributed throughout our genome, but are concentrated among genes that regulate transcription, growth, metabolism, differentiation, and oncogenesis. Alterations in MVP methylation status create epigenetic patterns that appear to regulate gene expression profiles during cell differentiation, growth, and development, as well as in cancer. Environmental stressors including toxins, as well as microbial and viral exposures, can change epigenetic patterns and thereby effect changes in gene activation and cell phenotype. Since DNA methylation is often retained following cell division, altered MVP patterns in tissues can accumulate over time and can lead to persistent alterations in steady-state cellular metabolism, responses to stimuli, or the retention of an abnormal phenotype, reflecting a molecular consequence of gene-environment interaction.

The occurrence of "large offspring syndrome" in cattle is attributed to exposure of embryos in vitro to environmental changes. A similar condition, "Beckwith-Weidmann syndrome", which is an imprinted disorder was found to occur with increased frequency in children born by "assisted reproductive technologies". Therefore, environmental factors might cause epigenetic modification of DNA leading to alteration of "imprinted gene expression".

Alterations in gene expression are implicated in the pathogenesis of several neuropsychiatric disorders, including drug addiction and depression. Changes in gene expression in neurons, in the context of animal models of addiction and depression, are mediated in part by epigenetic mechanisms that alter chromatin structure on specific gene promoters.

Aptamers
Aptamers are oligonucleotides that exhibit specificity against amino acids, drugs, proteins and other biomolecules. They are useful to purify other molecules. Aptamers, first reported in 1990, are attracting interest in the areas of therapeutics and diagnostics. They are ideal candidates for use as biocomponents in biosensors.
Chapter AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Recombinant DNA technology
2. Restriction endonucleases
3. Vectors
4. Molecular cloning
5. Gene therapy

Recombinant DNA Technology
i. Biotechnology may be defined as "the method by which a living organism or its parts are used to change or to incorporate a particular character to another living organism".

ii. Biotechnology involves the application of scientific principles to the processing of materials by biological agents.

iii. The use of new varieties of microorganisms to breakdown pollutants in soil or water to harmless end products is known as bioremediation.

iv. Genetic recombination is the exchange of information between two DNA segments. This is a common occurrence within the same species. But by artificial means, when a gene of one species is transferred to another living organism, it is called recombinant DNA technology. In common parlance, this is known as genetic engineering.

Applications of Recombinant Technology
1. Quantitative Preparation of Biomolecules
If molecules are isolated from higher organisms, the availability will be greatly limited. For example, to get 1 unit of growth hormone, more than 1000 pituitaries from cadavers are required. By means of recombinant technology, large scale availability is now assured.

2. Risk of Contamination is Eliminated
It is now possible to produce a biological substance without any contamination. Hepatitis, caused by the hepatitis B virus (HBV), is highly contagious. A vaccine is prepared from the Hepatitis B virus surface proteins, which will give protection from infection. Originally, the virus was isolated from pooled blood of patients, and the specific protein was isolated. However, blood of hepatitis patients is known to be highly infective. It is absolutely essential to make sure that the preparations of vaccines or clotting factors are free from contaminants such as hepatitis B particles. Recombinant DNA technology provides the answer to produce safe antigens for vaccine production.

3. Specific Probes for Diagnosis of Diseases
Specific probes are useful for:
   i. Antenatal diagnosis of genetic diseases. For example, many of the single gene defects (e.g. cystic fibrosis, phenyl ketonuria, etc.) could be identified by taking cell samples from fetus.
   ii. To identify viral particles or bacterial DNA in suspected blood and tissue samples.
   iii. To demonstrate virus integration in transformed cells.
   iv. To detect activation of oncogenes in cancer.
   v. To pinpoint the location of a gene in a chromosome.
   vi. To identify mutations in genes and for pedigree analysis: Point mutations, deletions, insertions and rearrangements of DNA could be identified. Sickle cell disease is an example of point mutation (See Chapter 22). The substitution of T for A in the template strand of DNA in the beta globin gene changes the Mst II restriction site (See Chapter 55). Thus normal, heterozygous and homozygous individuals in the family could be identified.

4. Gene Therapy
An important application of recombinant technology is in gene therapy. Normal genes could be introduced into the patient so that genetic diseases can be cured. These techniques are described later.
Restriction Endonucleases (RE)
The principle of DNA recombinant technology is summarized in Figure 43.4. In order to transfer a gene, it is to be first selectively split from the parent DNA. This is usually achieved by restriction endonucleases which are referred to as "molecular scissors".

Werner Arber showed that certain enzymes of bacteria restrict the entry of phages into host bacteria. Hence, the name restriction endonucleases. Hamilton Smith in 1970 isolated the first restriction enzyme beta Hind-I. Daniel Nathans in 1971 for the first time applied the enzyme to cut the DNA. All the three got Nobel Prize in 1978. Paul Berg (Nobel Prize 1980) developed the cutting technique for recombinant DNA.

Restriction Sites
Restriction endonucleases have specific recognition sites where they cut the DNA. (Table 43.1). There are more than 800 such enzymes now available commercially. These enzymes recognize specific sequence with palindrome arrangement. Palindrome in Greek means "to run backwards". It is similar to a word that reads backwards or forwards similarly, e.g. "madam". These are also called inverted repeat sequences, which means the nucleotide sequence in 5' to 3' direction is the same in both strands. The resultant DNA cuts will generally have overlapping or sticky ends (Fig. 43.2). Restriction endonucleases may also produce blunt ends, e.g. Hpa-I.

Restriction Map
The recognition site will be about 4 to 7 nucleotide pairs. If a piece of DNA from a species is made to react with a specific RE, a characteristic array of cut pieces will be produced, this is called a restriction map. These fragments can be isolated by electrophoresis. The restriction fragments serve as the "fingerprint of the DNA", because the fragments of DNA from one organism will have a characteristic pattern. For example, the restriction maps of lambda phage DNA with two restriction enzymes are given in Fig. 43.1.

VECTORS
In order to introduce the human gene into bacteria, at first, the gene is transferred into a carrier, known as a vector. Most commonly used vectors are plasmids. Plasmids are circular double-stranded DNA molecules seen inside bacteria. In nature, plasmids confer antibiotic resistance to host bacteria. This feature has profound significance in clinical practice because, antibiotic resistance property is exchanged between bacteria. Plasmids replicate
Fig. 43.3. Steps to produce cDNA from mRNA

1. Preparation of Specific Human Gene
Isolation of a specific gene from the human DNA is a laborious process. The beta globin gene is about 1.6 kbp length, which represents only 0.00005% of total human genes. This is like searching for a needle in a haystack. This problem is generally solved by preparation of cDNA (complementary copy DNA). It is easier to start the work with mRNA, because there is selective expression of a particular gene in certain tissue. For example, insulin mRNA will be abundant in the beta cells of pancreas. From the specific mRNA, the cDNA is produced by using reverse transcriptase (RT) (Fig. 43.3).

2. Preparation of Chimeric DNA Molecules
Chimera is the Greek mythological monster with a lion’s head, goat’s body and serpent’s tail. Narasimha (lion’s head and human body) is another example from Indian mythology. A vector carrying a foreign DNA is called Chimeric DNA or Hybrid DNA or Recombinant DNA. A summary of the procedure is given in Figure 43.3.

Procedure of DNA Recombination

i. A circular plasmid vector DNA is cut with a specific restriction endonuclease (RE). If EcoRI is used, sticky ends are produced with TTAA sequence on one DNA strand, and AATT sequence on the other strand (Table 43.1 and Fig. 43.4).

Fig. 43.4. Production of chimeric DNA molecule by using ECoRI restriction endonuclease. Red arrows show the site of cut by ECoRI

Bacteriophages and Cosmids
Plasmids can accept only about 6-10 kbp long foreign DNA. If a DNA segment of 10-20 kbp is to be introduced, bacteriophages may be the vectors of choice. The lambda phage DNA is linear, 40% of genome is nonessential. Therefore, in this region, a large fragment of foreign DNA may be introduced. Cosmid vectors can take up still bigger fragments of 20-50 kbp length. Cosmids are plasmids that contain DNA sequences (cos sites) required for packaging of lambda DNA into phage.
ii. The human DNA is also treated with the same RE, so that the same sequences are generated on the sticky ends of the cut piece.

iii. Then the vector DNA and human cut-piece DNA are incubated together so that annealing takes place. The sticky ends of both vector and human DNA have complementary sequences, and therefore they come into contact with each other.

iv. Then DNA ligase enzyme is added, which introduces phospho-diester linkages between the vector and the insert molecules. Thus the chimeric DNA is finally produced.

Homopolymer Tailing
The sticky ends of the vectors usually reconnect themselves without taking up the foreign molecule (recircularization). To circumvent this problem, homopolymer tailing is done in both vector and insert molecules. First the restriction enzyme, HpaI is used to produce blunt ends of vector. Then poly dG is added to the 3' end of foreign DNA and poly dC is added to the 3' end of vector DNA. When the two molecules are incubated, only hybrid varieties are formed.

3. Cloning of Chimeric DNA
The next step is cloning. A clone is a large population of identical bacteria or cells that arise from a common ancestor molecule. Cloning allows the production of a large number of identical DNA molecules. The hybrid molecules are amplified by the cloning technique.

4. Transfection of Vector into the Host
The process by which plasmid is introduced into the host is called transfection. Host E. coli cells and plasmid vectors are incubated in hypertonic medium containing calcium for a few minutes. Then calcium ion channels are opened, through which the plasmid is imbibed into the host cell. Now the host cells are allowed to grow in agar plates containing growth medium. Only 5% of bacterial colonies contain the desired vector. Therefore, we have to select the desired colonies.

5. Plasmid Carries Antibiotic Resistance Genes
Plasmid pBR-325 vector contains Apr (ampicillin resistance), Tcr (tetracycline resistance) and Cmr (chloramphenicol resistance) genes (see Fig. 43.5). The restriction enzyme EcoRI will cleave the plasmid in the middle of Cmr gene. When the foreign DNA is inserted, the resistance against chloramphenicol is lost. This insertional inactivation of Cmr gene is the marker for hybrid DNA.

6. Selection of Colony having Desired Gene
i. After the transfection, the bacteria are cultured in a medium containing ampicillin and tetracycline. The antibiotics kill all the wild bacteria. Only the bacteria containing the plasmids will grow.

ii. There will be many colonies, where the vector does not carry the foreign DNA. These colonies are replica-plated onto another agar plate containing chloramphenicol. Since the insertion of foreign DNA abolishes chloramphenicol resistance, the desired colonies are killed in the replica-plate.

iii. Colonies in the original plate, corresponding to the dead colonies in the replica-plate are selected. They carry the foreign gene (Fig. 43.6).

iv. The selected colonies are further cultured to produce clones. The principle of gene transfer technology is summarized in Figure 43.7.

7. Expression Vectors
To produce the human proteins, E. coli carrying the vector with the insert is allowed to grow, without any protein inhibitors. Such a vector carrying the foreign gene, which is translated into a protein, is called expression vector. The human proteins can be harvested from the bacterial culture.
Human Recombinant Proteins
Hundreds of human proteins are now being synthesized by the recombinant technology. Recombinant human insulin is now available in market. Other useful products thus produced are interleukins, interferons, anti-hemophilic globulin, hepatitis B surface antigen (for vaccination) and growth hormone.

Gene Library
Thousands of genes are arranged in specific order in the entire length of DNA. Isolation of the full length of DNA is practically impossible. To overcome this hurdle, the DNA of an organism is cut into small pieces of about 100 kbp by different restriction endonucleases. These cut pieces are then inserted into the vectors, and amplified in bacterial cells as recombinant DNA. A collection of these different recombinant clones, is called a gene library (Fig. 43.8).

Linkage Analysis
If two genes are close together on the same chromosome, they do not assort independently during meiosis. Such genes are said to be linked. When two genes are far apart, they are not linked even though they are on the same chromosome. The 2 alleles are co-inherited with greater frequency if they are physically located close to each other. From this, we can understand the sequentially placed genes as 1, 2, 3, etc. Linkage analysis was the first step taken for human genome project.

Human Genome Project (HGP)
US Department of Energy together with US National Institutes of Health started this project in 1990. James Watson (co-discoverer of the structure of DNA, Nobel laureate, 1962) was the first head of the project; later Francis Collins succeeded him. The project included scientists from 16 centres all over the world, mostly from USA, with co-ordination from laboratories of Britain, France, Japan and Germany. So, the Project was named as International Human Genome Sequencing Consortium. By 1997, Celera Genomics, headed by Craig Venter, a private enterprise funded by Perkin-Elmer Company independently embarked on a similar project, which hastened the work.

For HGP, the whole human DNA was fragmented into pieces of 100-200 kb length. These were matched with individual chromosomes by looking marker sequences. These areas were further broken into small pieces and sequenced (shotgun technique). Overlapping sequences were arranged, and fragments were re-written with the help of computer programs. It is one of the greatest achievements of humanity. The ambitious project was to decode the whole human genome and to sequence the whole human DNA. One set of human DNA contains about 3 billion base pairs (one cell contains 2 sets) and about 10,000 genes. The "Book of Human Life" contains "23 Chapters", as the 23 chromosomes.

The impact of HGP will be on all branches of medicine and related health sciences. It is now possible to isolate any human gene of interest. Many previously unknown genes have been identified. Pharmacogenomics is a recently emerged science from the genome project; it is the use of genetic information towards the development of new drugs and their targets of action.

By means of linkage analysis, human genetic mapping (location of important genes) was completed by 1994. The DNA sequences were identified by “shot gun sequencing” method, which involves breaking the DNA into small pieces, and sequencing each of them.

In 1995, gene map of chromosomes was published. By December 1998, human chromosome 5 (about 6% of human genome) was sequenced completely. By June 2000, "preliminary working draft" of the total human DNA sequence was announced. The final version of the sequence of the entire human genome was completed in 2003.
Other Projects on Gene Sequencing

In 2003, the National Human Genome Research Institute initiated the **ENCODE** (Encyclopedia of DNA Elements) Project. The consortium of research workers aim to identify all the functional elements of the genome.

**GENE THERAPY**
Gene therapy was once considered a fantasy. However, thousands of individuals have already undergone human clinical trials. A great leap in medical science has taken place on the 14th September 1990, when a girl suffering from Adenosine deaminase deficiency (severe Immuno-deficiency) was treated by transferring the normal gene for adenosine deaminase.

1. **What is Gene Therapy?**
   It is intracellular delivery of genes to generate a therapeutic effect by correcting an existing abnormality. Only **somatic gene therapy**, by inserting the new gene into somatic cell of the patient is under trial. Germ cell gene therapy is considered as unethical.

2. **Summary of the Procedure**
   1. Isolate the healthy gene along with the sequence controlling its expression.
   2. Incorporate this gene into a carrier or vector as an expression cassette.
   3. Finally deliver the vector to the target cells.

3. **How the Genes are Introduced?**
   There are 3 ways of applying gene carrying vectors:
   a. **Ex vivo strategy** where the patients' cells are cultured in the laboratory, the new genes are infused into the cells; and modified cells are administered back to the patient (Fig. 43.9).
   b. **In situ strategy** when the expression cassette is injected to the patient either intravenously or directly to the tissue (Fig. 43.10).
In vivo strategy, where the vector is administered directly to the cell, e.g. CF (cystic fibrosis) gene to the respiratory tract cells.

4. The Vectors
Different vector (carrier) systems used for gene delivery are: Retroviruses, adenoviruses, adeno associated viral vectors and herpes simplex viruses. Non-virus systems include liposomes, plasmids and physical methods.

4-A. Retroviruses
i. Retroviruses are RNA viruses that replicate through a DNA intermediate. Moloney Murine Leukemia Virus (MMLV) is commonly used. The gag, pol, env genes are deleted from the wild type retrovirus, rendering it incapable of replication inside human body. Then the human gene is inserted into the virus.

ii. This is introduced into a culture containing packaging cells having gag, pol and env genes (Fig. 43.10). These cells provide the necessary proteins to pack the virus.

iii. The replication-deficient, but infective, retrovirus vector carrying the human gene, now comes out of the cultured cells. These are introduced into the patient. The virus enters into the target cell via specific receptor.

iv. In the cytoplasm of the human cells, the reverse transcriptase carried by the vector converts the RNA to proviral DNA, which is integrated into the target cell DNA. The normal human gene can now express (Fig. 43.10).

v. Advantage of Retroviruses: The virus is modified, and replication deficient. So infection with viral particle is limited to one cycle, and is very safe. They can infect a wide variety of human cells. This strategy is very suitable for treatment of all diseases produced by single gene mutations.

vi. Disadvantage of Retroviruses: Retrovirus requires dividing cells as the targets, and allows only low titers of virus to be generated. Moreover, insertional mutagenesis is a theoretical possibility.

4-B. Adenoviruses
Adenoviruses are DNA viruses. The virus carrying the human gene reaches the nucleus of target cells. It is not integrated, but remains as episomal (episomal). Advantage of adenovirus is that they offer high titers and easier ability to infect wide variety of cells. Disadvantage of adenovirus is that the expression is usually transient, the useful effect varying from a few weeks to months only.

4-C. Plasmid Liposome Complex
It is a non-viral vector system. Liposomes are artificial lipid bilayers, which could be incorporated with plasmids carrying the normal human DNA. The complexes can enter into the target cells by fusing with the plasma membrane (Fig. 43.11). Cationic liposomes (positively charged) can form complexes spontaneously with DNA (negatively charged). The advantages

Box 43.1. What happened to gene therapy trials?
A few patients treated by gene therapy for diseases like SCID, developed leukemia and died. The gene introduced through a retroviral vector got inserted at a site (illegitimate recombination) that led to activation of oncogenes that resulted in leukemia. At present trials are on, but restricted with stringent protocols and follow up.

with this strategy are that the vector can carry human gene of big size, do not replicate and evoke only very weak immune responses. The disadvantage is that most of the complexes are destroyed inside the host cell, and so the efficiency of gene transfer is less.

4-D. Gene Gun Method
Tungsten particles are coated with plasmid DNA, and accelerated by helium pressure discharge. This enables particles to penetrate the target tissues. It is quick, and could be used in almost all tissues. Cellular damage and transient gene expression are the drawbacks.

5. Accomplishments
Gene therapy is effective in inherited disorders caused by single genes. Several clinical trials have been conducted. However, the progress is slow and it will take decades to make it a common clinical procedure. Success stories are few. The most dazzling ones are shown in Table 43.2:

6. Obstacles to Success
The potential of gene therapy is enormous. It is now theoretically possible to cure all the genetic diseases. However, it may take several years to get it available for common clinical use. The following limitations are encountered for gene therapy: (a) Inconsistent results. (b) Lack of ideal vector. (c) Lack of targetting ability in nonviral vectors. (d) Death during the course of gene therapy for OTC (ornithine transcarbamoylase) deficiency was reported. (e) Reactivation of retroviral vector due to illegitimate combination of the inserted gene leading to leukemia in the patient has posed a setback in this field (See Box 43.1).

STEM CELLS
Stem cell research is leading to promising results in treatment of various incurable diseases like coronary artery disease and cancer. Mario R Capecchi, Sir Martin J Evans and Oliver Smithies were awarded Nobel Prize in 2007 for their discoveries of principles for introducing specific gene modifications in mice by the use of embryonic stem cells. Stem cells have the ability to divide for an indefinite period. They can give rise to a variety of specialized cell types. This phenomenon is known as developmental plasticity. Stem cells can be isolated from embryos, umbilical cord as well as any other adult tissue. Plasticity is more for embryonic stem cells.

Stem cells have the unique capacity to produce unaltered daughter cells (renewal) and also to generate specialized cells (potency). Stem cells may be capable of producing all types of cells of the organism (totipotent), or able to generate cells of the three germ layers (pleuripotent), or able to produce only closely related cell types (multipotent), or may produce only one cell type (unicipotent). Stem cells may be embryonic (capable to differentiate) or adult type (limited capacity to differentiate). The pluripotency and self-renewal are critical for sustaining the lifelong functions of organs. Stem cells reside in a special microenvironment called the niche. Stem cells interact with the niche via adhesion molecules and exchange molecular signals that maintain the specific features of stem cells. A schematic diagram of development of differentiated cells from the stem cell is shown in Fig. 43.12. Active research is being done to utilize stem cells in the treatment of the following diseases: Stroke, brain injury, Alzheimer's disease, Parkinsonism, wound healing, myocardial infarction, muscular dystrophy, spinal cord injury, diabetes, cancers. It has been suggested that tumor tissue contains a type of stem cell referred to as a cancer stem cell.

Related topics
Molecular biology techniques such as hybridization techniques, cloning, DNA fingerprinting, RFLP, PCR, hybridoma technology, DNA sequencing, etc. are described in Chapter 55.
The nervous system and endocrine system are the major control mechanisms that integrate the functions of the tissues in the body. The nervous system transmits electrochemical signals between the brain and peripheral tissues for coordinating the diverse body functions. The endocrine system releases chemical mediators or hormones into the circulation. However, both these systems converge, so that neural regulation of endocrine glands is effected. Moreover, neurotransmitters have several features in common with hormones. E.H. Starling in 1905 introduced the term "hormone".

The classical definition of a hormone is "substances released from ductless or endocrine glands directly to the blood". A more modern definition of a hormone is that it is synthesized by one type of cells and transported through blood to act on another type of cells. Based on mechanism of action, the hormones may be classified into two (Table 44.1).

1. Hormones with cell surface receptors
2. Hormones with intracellular receptors

### 1. Hormones Acting through Cyclic AMP (cAMP)
Cyclic AMP was first discovered by Earl Sutherland in 1961, who was awarded Nobel prize in 1971.

#### 1-A. Signal Transduction through G protein
Action is through G protein coupled receptors (GPCR). Binding of different types of signal molecules to G protein coupled receptors is a general mechanism of signal transduction. Action of several hormones is effected through this

![Fig. 44.1. Synthesis, degradation of cyclic AMP](image-url)
Mechanisms of Action of Hormones

**Fig. 44.2.** Inactive and active forms of G-protein mechanism (Table 44.1). The GPCRs are transmembrane proteins with 7 helical segments spanning the membrane.

When any ligand binds, the GPCRs activate heterotrimeric GTP binding regulatory proteins (G-proteins). The G-protein in turn will interact with effector proteins which may be enzymes or ion channel proteins, which result in the desired effect. Different types of G proteins are present in the cells that are coupled with different receptors and activating different effector proteins.

The extracellular messenger, the hormone (H) combines with the specific receptor (R) on the plasma membrane (Fig. 44.3). The H-R complex activates the regulatory component of the protein designated as G-protein or nucleotide regulatory protein. G proteins are so named, because they can bind GTP and GDP. The G-protein is a membrane protein consisting of alpha, beta and gamma subunits (Fig. 44.3). Alfred Gilman and Martin Rodbell were awarded Nobel prize in 1994 for their work on G protein.

**1-B. G Protein Activates Adenyl Cyclase**

When the hormone receptor complex is formed, the activated receptor stimulates the G protein, which carries the excitation signal to adenylate cyclase. (Fig. 44.4-2).

**Fig. 44.3.** Hormone binding activates G-protein
The hormone is not passed through the membrane; but only the signal is passed; hence this mechanism is called **signal transduction**. The adenyl cyclase is embedded in the plasma membrane (Fig. 44.4).

**1-C. Subunit Activation of G-Protein**
The inactive G protein is a trimer with alpha, beta and gamma subunits. When activated, GTP binds and the beta-gamma subunits dissociate from the alpha subunit. Adenylate cyclase is activated by G-alpha-GTP (Fig. 44.4-2). The binding of hormone to the receptor triggers a configurational change in the G protein which induces the release of bound GDP and allows GTP to bind. The hormone has an amplified response, since several molecules of G-alpha-GTP are formed.

**1-D. Inactivation**
The active G-alpha–GTP is immediately inactivated by GTPase. The G-alpha–GDP form is inactive (Fig. 44.2). The activation is switched off when the GTP is hydrolysed to GDP by the GTPase activity of the alpha subunit (Fig. 44.2). This is a built-in mechanism for deactivation. The alpha subunit, which is bound to GDP, can re-associate with beta and gamma subunits. The GTP-GDP exchange rate decides the activity of adenyl cyclase.

**1-E. Cyclic AMP (cAMP)**
Adenyl cyclase or adenylate cyclase converts ATP to cAMP (3',5'-cyclic AMP), and phosphodiesterase hydrolyses cAMP to 5' AMP (Fig. 44.1). Structure of cAMP is shown in Figure 39.8. Table 44.1 contains the list of hormones mediated through cyclic AMP. Box 44.2 shows the hormones which stimulate or inhibit the adenyl cyclase. Cyclic AMP is a second messenger produced in the cell in response to activation of adenylate cyclase by active G protein. During hormonal stimulation, cyclic AMP level in the cell increases several times.

The level of cyclic AMP in the cell is regulated by its rate of production by adenylate cyclase (AC) and hydrolysis by phospho diesterase (PDE). The action of PDE is also regulated by hormones and drugs. Therefore, cellular level of cyclic AMP can be increased by inhibition of PDE. E.g. Insulin activates PDE, decreasing the cellular level of cAMP while caffeine and theophylline inhibit PDEs increasing cAMP levels.

**1-F. Second Messenger Activates PK**
The cAMP (second messenger), in turn, activates the enzyme, PKA (Cyclic AMP dependent protein kinase). Cyclic AMP binds to the regulatory subunits of PKA so that the catalytic subunits having kinase activity can phosphorylate proteins. The cascade

---

**Box 44.1. Mechanism of Action of Some Toxins**

**Cholera** toxin is encoded by a bacteriophage present inside the bacteria *Vibrio cholerae*. The enterotoxin contains two A subunits and 5 B subunits. The B subunit binds to a ganglioside GM1 on the surface of intestinal mucosal cell. The A subunit then enters into the inner part of the membrane, which leads to ribosylation of the alpha subunit of Gs protein. This results in the inhibition of the inherent GTPase activity and irreversible activation of G protein. Therefore, adenyl cyclase remains continuously active and keeps cyclic AMP levels high. This prevents absorption of salts from intestine leading to watery diarrhea and loss of water from body. In the large intestine, chronic elevation of cAMP results in a sustained PKA mediated phosphorylation of chloride channels (CFTR) that normally regulate salt and water transport. Hyperactivity of these channels will result in loss of sodium chloride with watery diarrhea (liquid stools), that may have fatal results. The patient may lose as much as 1 L of water per hour.

**Pertussis** toxin ribosylates the alpha subunit of Gi protein and prevents the Gi-GDP complex from interacting with the activated receptor. Hence, the action of hormones acting through Gi is inhibited.

Effects of bacterial toxins from *Clostridium tetani* are exerted through proteases, that attack proteins involved in synaptic vesicle and plasma membrane fusion. The toxin has two polypeptides, one of which binds to cholinergic motor neurons and facilitates the entry of the second polypeptide. It is a protease that cleaves the protein necessary for vesicle fusion. Failure to release the neurotransmitter leads to fatal paralysis of the chest muscles.

---

**Box 44.2. Hormones acting through Adenyl Cyclase**

**Hormones stimulate adenyl cyclase:** ACTH, ADH, Calcitonin, CRH, FSH, Glucagon, epinephrine, hCG, LH, LPH, MSH, PTH and TSH

**Hormones inhibit adenyl cyclase:** Acetyl choline, Angiotensin II and Somatostatin.
amplification effect is seen in this series of activation reactions. This PKA is a tetrameric molecule having two regulatory (R) and two catalytic (C) subunits (R2 C2) (Fig. 44.4-3). This complex has no activity. But cAMP binds to the regulatory subunit and dissociates the tetramer into regulatory and catalytic subunits (Fig. 44.4-4). The catalytic subunit is now free to act.

1-G. Kinase Phosphorylates the Enzymes

The catalytic subunit then transfers a phosphate group from ATP to different enzyme proteins (Fig. 44.4-5). Phosphorylation usually takes place on the OH groups of serine, threonine or tyrosine residues of the substrates. The enzymes may be activated or inactivated by this phosphorylation. This is an example of covalent modification. A summary of the cascade activation of enzymes by the hormone is shown in Figure 44.5. Glycogen phosphorylase (Fig. 9.38) and hormone sensitive lipase (Fig. 11.16) are controlled by cyclic AMP. The hormones that are acting through cyclic AMP are enumerated in Table 44.1.

There are Many G-Proteins

About 30 different G-proteins are identified, each being used for different signal transduction pathways. The G protein, which stimulates adenylyl cyclase, is called Gs (G stimulatory) and the opposite group is called Gi (G inhibitory). An example of inhibitory G protein is the inhibition of adenylate kinase. The alpha subunit of the Gs and Gi are different, but beta and gamma are the same. G proteins are also involved in toxic manifestations of cholera and pertussis (Box.44.1).

There are Many Protein Kinases

More than thousand protein kinases are now known. Some important hormone responsive protein kinases are, cAMP-dependent kinases, epidermal growth factor-dependent tyrosine kinase, insulin-dependent tyrosine kinase. All the known effects of cAMP in eukaryotic cells result from activation of protein kinases, which are serine/threonine kinases.

Glycogen Phosphorylase is a Typical Example

Glycogen phosphorylase and hormone sensitive lipase are activated by cAMP mediated cascade (Figs 44.5 and 11.16). Table 44.1 contains the list of hormones, where cyclic AMP is the second messenger.

The termination of the effect of the hormonal action by phosphorylation is effected by the action of protein phosphatases. For example, glycogen phosphorylase becomes inactive in the dephosphorylated state. But, glycogen synthase is active in dephosphorylated state (Fig. 9.39).

Certain enzymes are activated by dephosphorylation (Table 5.8). Hepatic Protein Phosphatase-1 is a typical example where the enzyme itself is inhibited by phosphorylation of its regulatory subunit. When cyclic AMP level falls, the regulatory subunit is dephosphorylated and protein phosphatase becomes active, which in turn hydrolyses phosphate group from the enzyme. Protein kinases as well as protein phosphatases are involved in the action of different hormones. The actions of cAMP in eukaryotic cells are multifaceted and these include:

A. Activation of Protein kinase and phosphorylation of effector proteins like enzymes and ion channels. These enzymes may directly phosphorylate enzymes or secondary kinases that phosphorylate other enzyme. For example,
   i. PKA phosphorylates hormone sensitive lipase thus activating it.
   ii. Phosphorylase Kinase that phosphorylates glycogen phosphorylase.
   iii. When ion channel proteins or transporters are phosphorylated, the membrane potential is modified, thus regulating the influx of calcium.

B. cAMP also has a long lasting effect on gene expression. The translocation of the active PKA subunits to the nucleus induces phosphorylation of cAMP regulated gene regulatory proteins or CREBs. These proteins will bind to cAMP sensitive regulatory elements (CRE) on genes, thus controlling their expression.

2. Calcium Based Signal Transduction

Calcium is an important intracellular regulator of cell function like contraction of muscles, secretion of hormones and neurotransmitters, cell division and regulation of gene regulation. Rapid but transient increase in cytosolic calcium result from either opening of calcium channels in the plasma membrane or calcium channels in the ER. The released calcium can be rapidly taken up by ER to terminate the response.

The intracellular calcium concentration is low (10⁻⁷) whereas extracellular calcium concentration is very high (10⁻³), maintaining a 10,000 fold calcium gradient across the membrane. The inside has a negative potential therefore influx of calcium is rapid. Even small increase in cytosolic free calcium can have maximal effect on calcium regulated cellular functions. There are mainly 3 types of calcium transport systems.

a. Voltage gated calcium channels
b. Sodium/calcium antiport transporter
c. Calcium transporting ATPase

The calcium transporting ATPase transporter accumulates calcium within the lumen of ER
(sarcoplasmic reticulum) in muscle. These calcium ions can be released into the cytoplasm by an Inositol triphosphate (IP3) gated calcium channel or by a ligand gated calcium release channel (ryanodine receptor).

When cytosolic calcium increases, binding regulatory proteins, activation of several calcium binding regulatory proteins occurs. Calmodulin is expressed in various tissues and mediates the regulatory actions of calcium ions. Calcium binding causes conformational change in calmodulin resulting in interaction with kinases, phosphatases, NOS etc. Some of these CAM kinases can phosphorylate a wide range of proteins that alter cellular functions. When bound to calmodulin, CAM Kinase II also auto-phosphorylates, so that its activity is sustained. Intracellular calcium acts as a mediator of hormone action either independently or in conjunction with cAMP. As an example, see phosphorylase kinase reaction, in Chapter 9.

Hormones can increase the cytosolic calcium level by the following mechanisms:

A. By altering the permeability of the membrane.
B. The action of Ca-H+ ATPase pump which extrudes calcium in exchange for H+.
C. By releasing the intracellular calcium stores.
D. Calmodulin, the calcium dependent regulatory protein within the cell has four calcium binding sites. When calcium binds there is a conformational change to the calmodulin, which has a role in regulating various kinases. Calmodulin is a 17 kDa protein which has structural and functional similarity with the muscle protein troponin C. Examples of enzymes or functional proteins regulated by calmodulin are: Adenyl cyclase, calcium-dependent protein kinases, calcium-magnesium-ATPase, cyclic nucleotide phosphodiesterase, nitric oxide synthase and phosphorylase kinase.

3. Hormones Acting through PIP2 Cascade

The major player in this type of signal transduction is phospholipase C that hydrolyses phosphatidyl inositol in membrane lipids to 1,4,5-Inositol triphosphate (IP3) and Diacyl Glycerol (DAG) that act as second messengers. PIP3 (Phosphatidylinositol 3,4,5- phosphate) is another second messenger produced by the action of a phosphoinositide kinase. The phospholipase C may be activated either by G proteins or calcium ions. DAG can also be generated by the action of phospholipase D that produces phosphatidic acid which is hydrolyzed to DAG.

The binding of hormones like serotonin to cell surface receptor triggers the activation of the enzyme phospholipase-C which hydrolyses the phosphatidylinositol to diacylglycerol. IP3 can release Ca++ from intracellular stores, such as from endoplasmic reticulum and from sarcoplasmic reticulum (Fig. 44.6). The elevated intracellular calcium then triggers processes like smooth muscle contraction, glycogen breakdown and exocytosis.

PIP3 can be formed by the action of PI3-kinases that are activated through growth factors and cytokine mediated receptor tyrosine kinases. PIP3 which is a lipid second messenger has a role in regulation of cell motility, membrane trafficking and

---

**Fig. 44.5. cAMP mediated cascade**

**Fig. 44.6. PIP2 and DAG acting as second messengers.** PIP2 = phosphatidyl inositol bisphosphate. IP3 = inositol triphosphate. DAG= di acyl glycerol. PLC = phospholipase C. PKC = protein kinase C
cell survival signaling pathways. The major mediator of PIP3 action is PKB (Protein kinase B) which has a role in glucose transport, glycogen metabolism and cell death signaling pathways.

There is “cross talk” between the various signal transduction pathways that are co-ordinately regulated.

4. Diacylglycerol (DAG) Pathway
DAG, the messenger formed by the hydrolysis of PIP2 activates protein kinase C (PKC) which in turn would phosphorylate other target proteins. PKC activates several serine threonine kinases that phosphorylate several substrates including transcription factors, ion channels and transporters. Most effects of IP3 and DAG are found to be synergistic. DAG also increases the affinity of protein kinase-C for calcium. The enzymes are thus activated, even at physiological levels of calcium within the cell.

5. Role of Cyclic GMP (cGMP)
Cyclic GMP is another important second messenger involved in contractile function of smooth muscles, visual signal transduction and maintenance of blood volume. Cyclic GMP degradation is catalyzed by membrane bound PDEs.

i. It is formed from GTP by the action of guanyl cyclase. Several compounds have been found to increase the concentration of cGMP by activating guanyl cyclase.

ii. These include drugs like nitroprusside, nitroglycerine, sodium nitrite and atriopeptides (a group of peptides produced by atrial cardiac tissue). All these compounds act as potent vasodilators, by inhibiting the phosphodiesterase. See mechanism of action of nitric oxide (Chapter 16).

iii. Cyclic GMP activates cGMP-dependent protein kinase G (PKG), which phosphorylates important effector proteins that can regulate calcium dependent contraction or motility through modulating calcium influx. Examples are smooth muscle myosin, leading to relaxation and vasodilatation.

iv. Cyclic GMP is also involved in the rhodopsin cycle. The role of cGMP in the light sensing cells of retina and its interaction with the G protein transducin is described under visual cycle (Chapter 33).

v. NO (Nitric oxide) is the major activator of guanylate cyclase. NO in turn is produced by the action of NOS (Nitric oxide synthase) in tissues like vascular endothelial cells. (See Chapter 16). NO can easily diffuse through the membrane and activate guanylate cyclase. Increased level of cyclic GMP in smooth muscle triggers rapid and sustained relaxation of the smooth muscles. The vasodilatation resulting from NO induced increase in cGMP has great physiological and pharmacological significance. The drugs that act via NO release are nitroprusside, nitrites (used in angina as
Hormones with Intracellular Receptors

i. The hormones in this group include the steroid hormones and thyroid hormones. They diffuse through the plasma membrane and bind to the receptors in the cytoplasm (Fig. 44.8).

ii. The hormone receptor (HR) complex is formed in the cytoplasm. The complex is then translocated to the nucleus. Steroid hormone receptor proteins have a molecular weight of about 80-100 kD. Each monomer binds to a single steroid molecule at a hydrophobic site, but on binding to genes they dimerise (Fig. 44.7).

iii. In the nucleus, the HR binds to the hormone response elements (HRE) or steroid response elements (SRE) (Table 44.2). The SRE acts as an enhancer element and when stimulated by the hormone, would increase the transcriptional activity (Fig. 44.8). The newly formed mRNA is translated to specific protein, which brings about the metabolic effects. Binding to the SRE sequence leads to dimerization of the receptor. Steroid hormones influence gene expression, so that the rate of transcription is increased. The stability of mRNA is also increased. This would lead to induction of protein synthesis. Steroid receptors have been found to enhance initiation of transcription by formation of complexes at promoters (Fig. 44.7).

iv. Best examples of the effect of hormones on genes are:

a. The induction of synthesis of amino transferases by glucocorticoids.

b. Synthesis of calcium binding protein by calcitriol (Fig. 33.10).

coronary vasodilators) and sildenafil citrate (Viagra). Even though nitroglycerine was used to relieve angina for the last few decades, its role as an exogenous NO donor has been described only recently.

Insulin Signaling Pathway

Insulin acts by binding to a plasma membrane receptor on the target cells. Insulin receptor is described in detail in Chapter 24. It has 2 alpha and 2 beta subunits. Insulin binds with the alpha units. This binding activates the tyrosine kinase activity of the beta subunit, leading to auto-phosphorylation of the beta subunit (Fig. 24.7). This event, in turn, phospho-lates insulin receptor substrates (IRS). There are different IRS molecules, named as IRS 1 to 4.

Activation of IRS2 results in activation of the PI-3 kinase, which eventually activates various protein kinases, PKB, PKC, SGK (serum and glucocorticoid regulated kinase) etc. This leads to transcription of specific genes for key enzymes of glycolysis, such as glucokinase. There are more than 100 enzymes influenced by insulin.

An alternate pathway involves activation of IRS1. The message is later transmitted into a series of serine/threonine kinases, such as IRS2 → GRB2 → mSOS → Ras → Raf → MEK → MAPK, etc. which causes cell growth and new DNA synthesis. GRB= growth factor receptor binding protein; mSOS = mammalian son of sevenless; MAPK = mitogen activated protein kinase. IRS is further described in Chapter 48.

A third pathway is IRS3 → mTOR → p70S6K. (mTOR= mammalian target of rapamycin; p70S6K = p70 ribosomal protein S6 kinase). This pathway leads to increased synthesis of glucose transporters, insulin receptors, etc.

mTOR

Mammalian target of rapamycin (mTOR) also known as FK506 binding protein 12-rapamycin associated protein 1 (FRAP1) is a protein which in humans is encoded by the FRAP1 gene. The mTOR is a serine / threonine protein kinase that regulates cell growth, cell proliferation, cell motility, cell survival, protein synthesis, and transcription. The mTOR integrates the input from upstream pathways, including insulin, growth factors (such as...
as IGF-1 and IGF-2), and mitogens. It also senses cellular nutrient and energy levels and redox status. The mTOR pathway is dysregulated in certain cancers. Rapamycin is a bacterial product that can inhibit mTOR by associating with its intracellular receptor FKBP12. The FKBP12-rapamycin complex binds directly to the FKBP12-Rapamycin Binding (FRB) domain of mTOR.

**Jak/STAT Pathway**
Some hormones (GH, prolactin, erythropoietin, cytokines) when complexed with the receptor, activate cytoplasmic tyrosine kinases, such as Tyk, Jak, etc. (Jak means Janus kinase. Janus is a Greek mythological figure with two heads; the name is given because Jak dimerises. The name for the month of January is also derived from this Janus; January faces both the previous and present year). Jak in turn activates STAT (signal transducers and activators of transcription). The phosphorylated STAT dimerises and translocates into the nucleus, where it binds to a specific DNA element and activates transcription.

**NFkB and Glucocorticoids**
NFkB is the abbreviation for nuclear factor kappa-light-chain-enhancer of activated B cells. It is a protein complex that controls the transcription of DNA. NFkB is found in almost all animal cell types and is involved in cellular responses to stimuli such as stress, cytokines, free radicals, ultraviolet irradiation, oxidized LDL, and bacterial or viral antigens. NF-kB plays a key role in regulating the immune response to infection. Conversely, incorrect regulation of NFkB has been linked to cancer, inflammatory and autoimmune diseases, septic shock, viral infection, and improper immune development. NFkB has also been implicated in processes of synaptic plasticity and memory. Active NF-kB turns on the expression of genes that keep the cell proliferating and protect the cell from conditions that would otherwise cause it to die via apoptosis. NFkB is a transcription factor. It is a heterodimeric complex; it has two subunits, p50 and p65. Normally NF-kB is in cytoplasm, and is complexed with inhibitors, and so is inactive. Stimuli such as cytokines, ROS, mitogens will activate IKK (=IkB kinase), which phosphorylates I kB (=inhibitor of NF-kB). Phosphorylated I kB is attached with ubiquitin and is degraded by proteasomes. So, NFkB is now free, which translocates to nucleus. It binds to various gene promoters and activates transcription of proteins involved in inflammatory response. Glucocorticoids are used widely in clinical practice as anti-inflammatory agents. Glucocorticoids increase IkB; the glucocorticoid receptors bind to the p65 subunit of NFkB; in both ways glucocorticoids inhibit the NFkB activity, and so reduce the inflammation.

**Nuclear Receptors**
Their middle region contains the DNA binding domain (DBD) through which they bind the specific region of DNA, termed hormone response elements (Table 44.2). The receptors also have a ligand binding domain (LBD) at the carboxy terminal half. A hinge region separates the DBD and LBD regions. Nuclear receptors were identified for all the hormones listed in Table 44.2.

**CREB Binding Protein (CBP/p300)**
The CBP binds to CREB and mediates activation in response to cAMP. CRE means, cAMP sensitive regulatory elements. CBP and p300 are closely related proteins. p300 is so named, because it is a protein with molecular weight of 300 kD. Most of the signalling pathways finally converge in the CBP (Fig. 44.9). The final effector, CBP has the histone acetyl transferase activity, by which the DNA region is made available for transcription.

**Related Topics**
Insulin and glucagon (Chapter 24); adrenalin and noradrenalin (Chapter 17); renin, angiotensin (Chapter 30); calcitriol (Chapter 33); parathyroid hormone and calcitonin (chapter 35). C-Jun, C-kit, EGFR, ERK, GSK, GCSF, GMCSF, HSP, HGF, HER2/neu, IRS, JNK, MAPKK, MMP, p38, p53, p70S6, Rantes, Rb, STAT, TGF, TNF, VCAM and VEGF are described in Chapter 48.
CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Anti-diuretic hormone
2. Oxytocin
3. Hypothalamic releasing factors
4. Growth hormone
5. Adrenocorticotropic hormone
6. Thyroid stimulating hormone
7. Gonadotropins

The hypothalamus produces two types of endocrine factors; (a) the hypothalamic neuropeptides and (b) the hypothalamic releasing factors. The releasing factors are inhibitory neuro-secretions synthesized in the hypothalamus and released through the hypothalamic pituitary portal circulation. They have their effect on the secretion of pituitary tropic hormones.

1. HYPOTHALAMIC NEUROPEPTIDES
The hypothalamic neuropeptides are produced by the supra-optic and paraventricular nuclei of the hypothalamus. These neurohormones are anti-diuretic hormone (ADH) and oxytocin. The precursors of ADH and oxytocin are long polypeptides. They are synthesized in hypothalamus. It is cleaved into the active molecule, and then transported to posterior pituitary and stored there. They are released to blood stream by exocytosis.

1-A. Anti-Diuretic Hormone (ADH)
i. It is also called vasopressin. The structure is shown in Figure 45.1. If arginine is replaced by lysine, it is called lysine vasopressin (LVP).
ii. Its main action is to prevent diuresis. So it reduces the urine output. ADH acts on the distal convoluted tubules of the kidney, producing reabsorption of water.
iii. ADH binds to membrane receptor and activates adenylate cyclase. The cyclic AMP thus produced will activate the protein kinase. This, in turn, phosphorylates proteins of the microtubules and microfilaments. The net effect is the reabsorption of water.
iv. The regulation of ADH secretion is through the osmolality of blood. Lowering of the osmolality (hemodilution) suppresses ADH secretion. Conversely, an increase in osmolality (hemoconcentration or dehydration) leads to stimulation of the secretion of ADH.
v. Deficiency of ADH results in diabetes insipidus. It is characterized by excretion of large volumes of dilute urine. Hypernatremia and hypertonic contraction of extra...
cellular fluid volume are also seen. It is a very rare condition.

vi. Excess secretion of ADH often results from ectopic production of ADH by malignant tumors elsewhere, referred to as the syndrome of inappropriate secretion of ADH or SIADH. Here ADH is continuously secreted and is not subjected to any control mechanisms. There is hypotonic expansion of extracellular volume, with hyponatremia. Slow onset is mostly asymptomatic and goes unnoticed but those with acute onset will manifest the symptomatology of water intoxication (headache, confusion, anorexia, nausea, vomiting, coma and convulsions). Hyponatremia and impaired urinary dilution are seen.

1-B. Oxytocin

The term means “to stimulate birth”. Its structure is shown in Figure 45.1. Oxytocin acts on an estrogen-primed uterus. The synthetic derivative of oxytocin, Pitocin, is used to induce labor.

Oxytocin has an effect on the mammary glands. Suckling generates a neurogenic reflex, which stimulates the production of oxytocin. It causes contraction of the myo-epithelial cells expelling the milk into milk ducts from the acini.

2. HYPOTHALAMIC RELEASING FACTORS

Andrew Schally in 1971 isolated TRH. Roger Guillemin isolated LHRH (now termed GnRH) and somatostatin in 1973; both of them were awarded Nobel prize in 1977. The secretion of hormones by adenohypophysis or anterior pituitary is under the control of peptides secreted by hypothalamus. Several peptides having effects on anterior pituitary, either stimulant (releasing factors), or inhibitory, have been identified. Table 45.1 shows a list of these factors. The secretion of the hypothalamic peptides are also under the feedback control of anterior pituitary tropic hormones (short loop feedback) as well as the target gland hormones (long loop feedback) (see Fig.45.2).

3. HORMONES OF ANTERIOR PITUITARY

The anterior pituitary hormones are tropic in nature, stimulating the secretion of hormones from target organs. Secretions of all these hormones are under the control of hypothalamic releasing or inhibitory factors. Table 45.2 lists them.

3-A. Growth Hormone (GH)

i. It is also called **somatotropin**. It is a single polypeptide chain with 191 amino acids. GH is synthesized by **acidophils** (somatotropic cells) of anterior pituitary.

ii. Plasma concentration of GH is less than 2 ng/ml during day time, with secretory peak appearing 3 hr after meals. Maximum level of GH is seen during deep sleep. For measurement of serum GH, the samples are collected during sleep and also during waking hours to assess the circadian rhythm.

iii. GH secretion is regulated by the balance between GHRH and GHIH (**somatostatin**). The regulation of secretion is predominantly inhibitory. Hypoglycemia stimulates GH secretion, and hyperglycemia suppresses it. The hypothalamic growth hormone releasing hormone (GHRH) stimulates GH synthesis and release. **Ghrelin**, a peptide derived from stomach induces GHRH and directly stimulates the release of GH. Somatostatin synthesized in the hypothalamus inhibits the GH secretion.

iv. The metabolic effect of GH is partly mediated by **somatomedin**; also known as insulin-like growth factor-1 (IGF-1). The growth of long bones is stimulated by this factor. IGF-1, the peripheral target hormone of GH exerts feedback inhibition.

v. GH increases the uptake of amino acids by cells; enhances protein synthesis, and produces positive nitrogen balance. The anti-insulin effect of GH causes lipolysis and hyperglycemia. The overall effect of GH is to stimulate growth of soft tissues, cartilage and bone. It is anabolic.

vi. Excess secretion by GH secreting tumor, leads to **gigantism** in children and **acromegaly** in adults.

vii. Deficiency of GH secretion in early childhood results in pituitary dwarfism. **Dwarfism** may also result from congenital deficiency of GH due to end organ resistance. It is treated by giving GH produced by recombinant technology.

viii. **Growth Hormone Stimulation Test by L-DOPA**: It is done in suspected cases of hypopituitarism. Normal subjects show a rise in GH concentration in the serum after L-Dopa but not in cases of GH deficiency.

3-B. Adrenocorticotropic Hormone (ACTH)

i. It is secreted as a large precursor molecule, known as pro-opio-melanocortin (POMC), with a molecular weight of 32 kD. It is cleaved to give about 30 different endorphins and several hormones. The major products are shown in Figure 45.3. The active ACTH is a polypeptide with 39 amino acids.

ii. The secretion of POMC is under the control of CRF. ACTH is released from the pituitary in a pulsatile manner, with a definite diurnal rhythm, the secretion being highest in the early morning, and minimum at midnight. This pattern of secretion is reflected in cortisol also.

iii. ACTH binds to specific receptors on the adrenal gland, then activates adenylate cyclase and so, cAMP level is raised. ACTH induces adrenocortical steroidogenesis through the melanocortin-2 receptor. Steroid hormones in turn cause feedback inhibition of HPA (hypothalamo-pituitary-adrenal axis).

iv. ACTH secreting tumors of pituitary will cause Cushing’s disease. Deficiency of ACTH secretion may occur as a part of panhypopituitarism.

v. **Cosyntropin Stimulation (Rapid ACTH) Test**: With rapid administration of ACTH, blood cortisol level will be raised. If there is adrenal insufficiency, adrenal gland cannot be stimulated by the administered ACTH and subnormal or low response of cortisol occurs.

vi. **Dexamethasone Suppression Test**: Dexamethasone, an analogue of cortisol suppresses ACTH hormone and cortisol production in normal subjects; but not in patients with Cushing’s syndrome.

3-C. Endorphins

Small peptides formed from POMC have endogenous morphine-like or opiate-like activity. They are responsible for increasing the threshold of pain, especially under conditions of stress. Morphine binds to the receptors for endorphins, by which morphine induces the pain relief.

3-D. Glycoprotein Hormones

TSH, FSH and LH are the glycoprotein hormones of pituitary. All the three are made up of two subunits. The alpha unit is common to all the three, while the beta subunit is specific for each of them.
The alpha unit is also common to human chorionic gonadotropin (HCG); so beta HCG is estimated as an index of pregnancy. Beta HCG is a tumor marker for choriocarcinoma.

3-E. Thyroid Stimulating Hormone (TSH) (Thyrotropin)

i. The TSH increases the secretion of thyroid hormones by stimulating all the steps of production of synthesis of thyroxine (Chapter 47). It acts through cAMP by binding with a receptor on thyroid cell surface.

ii. TSH secretion is stimulated by TRH. TRH also stimulates prolactin secretion. Whereas, the prolactin inhibitory factor (PIF) inhibits secretion of TSH to some extent. TSH secretion is also controlled by the level of thyroid hormones.

iii. High levels of TSH may occur due to primary hypothyroidism and lack of feedback control. Normal TSH level is 0.5-5 microunits per ml. Deficiency may occur as a part of hypopituitarism.

iv. Increased serum TSH levels are seen in primary hypothyroidism (3-100 times normal), Hashimoto’s thyroiditis, ectopic TSH secretion by tumors (lung, breast), and in thyroid hormone resistance. TSH is elevated in euthyroid patients during treatment of hyperthyroidism but TSH is low for 4-6 weeks after achieving euthyroid state in treated hyperthyroid patients.

v. Decreased levels are observed in primary hyperthyroidism, secondary hypothyroidism (pituitary origin), tertiary hypothyroidism (hypothalamic), subclinical hyperthyroidism (e.g. toxic multinodular goiter, exogenous thyroid hormone administration, autonomous thyroid hormone secretion) and in euthyroid sick syndrome.

3-F. Gonadotropins

i. They are LH (Luteinizing hormone) and FSH (Follicle stimulating hormone) from pituitary. The placenta also produces human chorionic gonadotropin (hCG). FSH and LH are secreted under the effect of gonadotropin releasing hormone (GnRH). Puberty does not set in until the pulsatile secretion of LH/FSH is started by hypothalamus. The fundamental change during puberty is a reduction in hypothalamic inhibition of LH/FSH release.

ii. FSH stimulates growth of ovarian follicles in females and spermatogenesis (Sertoli cells) in males.

iii. Testosterone in males (secreted by Leydig interstitial cells) and progesterone in females (secreted by corpus luteum), are increased under the influence of LH.

iv. The FSH secretion rises during the follicular phase of the menstrual cycle, reaches a peak by the 14th day and starts falling when ovulation occurs. Ovulation occurs as a result of positive feedback effect of estrogen producing the pre-ovulatory LH surge. The level of FSH and LH falls during the post-ovulatory phase, unless fertilization and implantation occur.

v. The gonadotropin production is under the feedback control by the sex hormones. High levels of FSH and LH are seen in post-menopausal women due to lack of this feedback. Abnormalities in gonadotropin secretion are listed in Table 45.3.

vi. FSH is a hormone found in humans and other animals. It is synthesized and secreted by gonadotropes of the anterior pituitary gland. FSH regulates the development, growth, pubertal maturation, and reproductive processes of the body. FSH levels are normally low during childhood and, in females, high after menopause. High FSH levels are an indication of subfertility and / or infertility. Diminished secretion of FSH can result in hypogonadism. This condition is typically manifested in males as failure in production of normal numbers of sperm. In females, cessation of reproductive cycles is commonly observed.

vii. Serum level of FSH is raised in primary gonadal failure, ovarian or testicular agenesis, castration, Klinefelter’s syndrome, alcoholism, menopause, orchitis and gonadotropin secreting pituitary tumors. Serum level of FSH is decreased in anterior pituitary hypofunction, hypothalamic disorders, pregnancy, anorexia nervosa, polycystic ovary disease, hemochromatosis, sickle cell anemia, and in hyperprolactinemia. In hypogonadism, if the levels of FSH and LH are lower than normal for the patient’s age, it suggests hypothalamic or pituitary disease and if more than normal, indicates gonadal problem.

viii. Serum level of LH is raised in primary gonadal dysfunction, polycystic ovary syndrome, postmenopausal women and in pituitary adenoma. Serum level of LH is decreased in pituitary hypothalamic impairment, Kallmann’s syndrome (isolated gonadotropin deficiency associated with anosmia or hyposmia), anorexia nervosa and severe illness.

3-G. Prolactin (PRL) (Somatomammotropin)

Prolactin secreted by lactotrophic cells of adenohypophysis is under the control of hypothalamus. Lactotropes hyperplasia is induced by estrogen (during last two trimesters of pregnancy). Its secretion is primarily controlled by inhibitory effect of dopamine and GABA. Its release is stimulated by TRH and vasoactive intestinal peptide. It controls the initiation and maintenance of lactation. PRL secretion is pulsatile; highest levels during rapid eye movement sleep and peak serum level occurs between 0400-0600 hrs. Prolactin stimulates lactation on estrogen primed breast. It increases synthesis of milk protein and fat. Hyperprolactinemia is a cause of infertility in females. Secretion of PRL is stimulated by TRH and inhibited by PIF.

Prolactin Stimulation Test by Chlorpromazine: Chlorpromazine increases PRL secretion by competitive inhibition of dopamine receptors in the hypothalamus and pituitary in normal individuals.

Prolactin Suppression Test by L-Dopa: Failure to respond to L- dopa indicates autonomous function of pituitary prolactin secreting cells.
CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:
1. Synthesis of steroid hormones
2. 17-keto steroids
3. Biological effects of glucocorticoids
4. Assessment of glucocorticoid secretion
5. Adrenal hyper- and hypofunction
6. Ovarian hormones
7. Testicular hormones

ADRENAL CORTICAL HORMONES

The adrenal cortex has three different zones each responsible for production of different classes of steroid hormones (C21, C19 and C18). The smallest and outermost zona glomerulosa produces the C21 steroids, mineralo-corticoids. They have effects on water and electrolyte balance. The middle zone of the adrenal cortex, the zona fascicularis produces the glucocorticoids mainly; and adrenal androgens and estrogens to a lesser extent. The innermost zona reticularis produces the androgens (C19) and estrogens (C18). Cortisone was isolated by Tadeus Reichstein; the structure was identified by Edward Kendall, while Philip Hench in 1948 showed its efficacy in rheumatoid arthritis. All the three were awarded Nobel prize in 1950.

1. Synthesis of Steroid Hormones

i. Cholesterol is first acted upon by desmolase and a 6-carbon unit is cleaved off, forming the 21 carbon steroid, pregnenolone (Fig. 46.1). It is a common precursor for all the steroid hormones. ACTH stimulates this step. This is the rate limiting step for synthesis of all steroid hormones.

ii. Progesterone is the first steroid hormone formed from pregnenolone in two steps. The beta hydroxyl group is converted to a keto group by a 3-beta-ol-dehydrogenase and the $\Delta^5$ double bond shifted to $\Delta^4$ (Fig. 46.2).

iii. Progesterone is further converted into glucocorticoids (Fig. 46.2), mineralocorticoids (Fig. 46.3) and sex steroids (Fig. 46.4).

iv. The major adrenal glucocorticoids are cortisol, cortisone and corticosterone in that order. The major mineralocorticoid is aldosterone, but 11-deoxy-corticosterone and corticosterone also have significant mineralocorticoid activity.

v. These reactions are effected by hydroxylation. These specific hydroxylases are mono-oxygenases. All these enzymes are NADPH dependent. These hydroxylation reactions are summarized in Figure 46.5.

vi. ACTH stimulates the synthesis of all steroid hormones by activating desmolase so that the availability of pregnenolone is increased.
2. Secretion of Adrenal Hormones
   i. Secretion of all adrenocortical hormones is under the control of ACTH.
   ii. The diurnal variation of secretion of cortisol (highest values early in the morning and minimum at night) parallels the pulsatile release of ACTH from anterior pituitary under the influence of CRF.
   iii. Cortisol exerts the negative feedback effect on ACTH secretion.
   iv. ACTH also increases the secretion of aldosterone.
   v. The level of aldosterone is also affected by position, highest values in upright posture and lowest while lying down.
   vi. All steroid hormones act through intracellular messengers and increase the rate of transcription.

3. Transport and Metabolism
   i. Approximately 70% of cortisol in blood is bound to an alpha-1-globulin called cortisol binding globulin (CBG) or transcortin.
   ii. About 20% is bound to albumin and the rest is free, which is the biologically active fraction. The half-life of cortisol is about 2 hours.
   iii. The steroid hormones are metabolized and inactivated by the liver. The major processes are reduction and conjugation.
   iv. The C21 steroids are reduced to their tetrahydro derivatives, which are excreted as their glucuronides or sulfates in urine.

4. Urinary Steroids
   i. The urinary steroids are referred to as 17-ketosteroids and 17-hydroxy steroids (see structure in Figure 46.6).
   ii. The 17-ketosteroids may be derived from both adrenal steroids and androgens from the gonads. However, the
Assessment of Glucocorticoid Secretion

1. Basal level of cortisol

The plasma cortisol level is determined by radio-immunoassay (RIA), enzyme-linked immunosorbent assay (ELISA) or chemiluminescent immunoassay (CLIA). The normal range is 5-25 microgram/dl at 9 AM and 2-5 microgram/dl at 10 PM. A loss of diurnal rhythm may be an early indication of disease.

2. Estimation of urinary free cortisol

The free cortisol in plasma is the biologically active fraction. A definite fraction of the unbound cortisol is excreted in urine unchanged. Estimation of this fraction is a sensitive index of adrenal activity. High levels are seen in hyperfunction and low levels in hypoactivity.

3. Plasma ACTH

Suppressed ACTH levels are seen in hyperadrenalism and high ACTH levels in hypoadrenalism as well as in Cushing’s disease. In hyperadrenalism due to ectopic ACTH secretion, ACTH levels are elevated.

5. Biological Effects of Glucocorticoids

The glucocorticoids, as the name suggests, mainly affect metabolism of glucose. The major biological effects of glucocorticoids are given in Table 46.1.
4. Dexamethasone suppression test: Dexamethasone produces a fall in cortisol secretion due to feedback suppression of ACTH. In normal people, the overnight suppression with low dose (2 mg) causes a 50% fall in the original value. But this dose may fail to produce suppression in cases of adrenal hyperactivity.

5. Urinary steroids: Estimation of 17-ketogenic steroids is indicated only in AG syndrome. Since the 24-hour excretion is measured, the diurnal variation is also taken care of. Estimation of 17 ketosteroids in urine is often very useful in observing the response of patients to suppression and simulation tests as well as to assess the effectiveness of replacement therapy.

6. Stimulation test: Infusion of synthetic ACTH (Synacthen or tetracosactrin) is given. In the absence of reserve, stimulation tests fail to evoke any response.

7. Metyrapone test: Metyrapone inhibits the hydroxylase enzyme. When it is given, cortisol is not formed. Then there is no feedback inhibitory effect. Hence alternate pathways of sex steroids are more operative and the urinary excretion of 17-ketosteroids tends to elevate.

8. CRH test: The test is of importance in establishing the cause of adrenal hyperfunction (primary, secondary or tertiary).

**Assessment of Adrenal Androgen Secretion**

These tests are done in cases of suspected adreno-genital (AG) syndrome. There is excessive production of adrenal androgens, leading to virilism and hirsutism.

1. Adrenal Hyperfunction

Hyperactivity of adrenal cortex may be due to primary defect in adrenal gland itself (Cushing's syndrome) or secondarily by excessive production of ACTH from pituitary (Cushing's disease) or ectopic ACTH production by other malignant tumors (Table 46.2).

2. Adrenal Hypofunction

The most common cause of adrenal hypofunction is primary adrenal insufficiency or Addison's disease. It is characterized by tiredness, dehydration, hyponatremia and hyperpigmentation (due to high ACTH levels and its MSH activity). The diagnostic findings are given in Table 46.3.

**Primary Hyperaldosteronism (Conn's Syndrome)**

This may result from an aldosterone secreting tumor. The condition may be diagnosed by:

- elevated plasma aldosterone levels and no change with posture
- plasma renin activity is decreased due to feedback effect
- serum electrolytes show hypernatremia and hypokalemia
- plasma pH is elevated (hypokalemic alkalosis)
- osmolality is elevated (hypertonic contraction).

Adrenogenital Syndrome (AG Syndrome)
There is congenital deficiency of steroid hydroxylases leading to deficient secretion of cortisol. Since cortisol, the major feedback effector is not present, ACTH secretion continues leading to congenital adrenal hyperplasia (CAH). Depending on the enzyme defect the manifestations also vary (Table 46.4).

21-Hydroxylase Deficiency is the most common type, where the production of cortisol is totally absent. The lack of feedback leads to increased androgen synthesis. This would result in virilization of female children who develop ambiguous genitalia. Precocious puberty is seen in male children. Early diagnosis and supplementation of cortisol is effective in children.

11-Hydroxylase Deficiency: In this condition, the symptoms are more serious. The hypertensive variety of the AG syndrome manifests and the child may not survive. A differential diagnosis of AG syndrome is given in Table 46.4.

Aldosterone in Blood
Increased levels are seen in primary aldosteronism such as Conn’s syndrome (aldosterone secreting adenoma) and in bilateral adrenal hyperplasia. Secondary aldosteronism: e.g. abuse of diuretics, cardiac failure, cirrhosis of liver with ascites, nephrotic syndrome, hypovolemia due to hemorrhage and transudation, pregnancy, mid and late luteal phases of menstruation and chronic obstructive airway disease. Drugs increasing the levels of aldosterone are angiotensin, estrogens, laxatives, loop diuretics, metoclopramide, oral contraceptives, potassium, sodium restriction, spironolactone and thiazide diuretics.

Decreased levels are seen in Addison’s disease, isolated aldosterone deficiency, syndrome of hypaldosteronism due to renin deficiency, excess deoxycorticosterone secretion, corticosterone, 25% of Turner’s syndrome, diabetes mellitus, acute alcoholic intoxication. Drugs decreasing the levels are angiotensin converting enzyme inhibitors (captopril, enalapril, linsinopril, glutethemide, deoxy corticosterone, prolonged heparin therapy, indomethacin, saline and saralasin.

SEX HORMONES
These are secreted by the gonads in response to pituitary gonadotropins (LH and FSH). Adolf Butenandt isolated estrogen (1929), progesterone (1934) and testosterone (1935), for which he was awarded Nobel prize in 1939.

Ovarian Hormones
They are C18 estrogens, C19 androgens and C21 progesterone. These are produced by the ovarian follicles. The follicular thecal cells produce C19 androgens. These are converted to C18 estrogens by granulosa cells, by aromatization of ring A and loss of C19 methyl group (Fig. 46.4). Estradiol is the most important estrogen. It is converted to estrone by liver. It is further hydroxylated to estriol, which is inactive. Estradiol is bound to plasma SHBG (sex hormone binding globulin). Estradiol

</table>
(E2) is the predominant sex hormone present in females; however, it is present in males, at lower levels, as well. Estradiol has not only a critical impact on reproductive and sexual functioning, but also affects other organs including the bones.

Estradiol enters cells freely and interacts with a cytoplasmic target cell receptor. After the estrogen receptor has bound its ligand, estradiol can enter the nucleus of the target cell, and regulate gene transcription, which leads to formation of messenger RNA. The mRNA interacts with ribosomes to produce specific proteins that express the effect of estradiol upon the target cell. Estradiol binds well to both estrogen receptors, ER-alpha, and ER-beta. Selective estrogen receptor modulators (SERMs) preferentially act on one of these receptors.

Regulation of Ovarian Hormones

i. FSH influences follicles to ripen, which produces estrogen. Estrogen level gradually increases in the second week of the menstrual cycle. Estrogen level is maximum 24 hrs before the LH peak.

ii. High doses of estrogen can suppress the LH release and, therefore, effective as contraceptive.

iii. Under the influence of estrogen, uterine endometrium proliferates, glands in endometrium are hypertrophied, ducts in mammary gland are proliferated and progesterone receptors are synthesized.

iv. LH level peaks 16 hr before the ovulation. The surge of LH induces the ovulation. The corpus luteum then starts secreting progesterone.

v. Under the influence of progesterone, endometrium enters the secretory phase, and prepares for implantation of the fertilized ovum.

vi. LH is required for maintenance of corpus luteum. If implantation occurs (day 22-24), the LH function is taken over by the hCG, produced by the cytotrophoblast cells of the early embryo. The hCG can be detected 5-7 days after missing a period.

vii. If implantation has not occurred, hormone levels are decreased and the secretory glands of the endometrium are denuded.

Clomiphen citrate competes with estrogen for receptors in hypothalamus, thus removing the feedback inhibition. So GnRH level is increased, with consequent high levels of LH and FSH, which may produce follicular stimulation and ovulation. Clomiphen is therefore used to produce ovulation in infertile females.

Certain breast cancers, especially in perimenopausal women are estrogen-dependent. In such patients, estrogen receptor antagonists (Tamoxifen) will block the estrogen receptors, and cancer cells tend to die.

Testicular Hormones

i. In humans, testosterone is the major male hormone, while in animals, it is androstenedione. Androgen is derived from Greek word, ander, meaning male.

ii. The Leydig cells (interstitial cells), secrete the androgens, under the influence of LH. LH is also called ICSH (interstitial cell stimulating hormone). The androgens exert feedback effect on LH secretion, through inhibition of GnRH. Thus, in patients with hypogonadism, LH level is high.

iii. FSH binds to Sertoli cells (basement membrane cells of seminiferous tubules) and promotes the synthesis of androgen binding protein (ABP). Thus high concentration of androgen is made available locally at the seminiferous tubules, at the site of spermatogenesis.

iv. In patients with azoospermia, the FSH level is very high, due to lack of negative feedback.

v. Androgens stimulate spermatogenesis, produce hypertrophy of prostate, seminal vesicles, muscle, bone and kidney cells. It is anabolic.

vi. Dihydrotestosterone (DHT) is the cause for the benign prostate hypertrophy, that affects more than 75% of men over the age of 60 years.

vii. The enzyme 5-alpha-reductase is needed to convert testosterone to DHT. Fenasteride can inhibit 5-alpha-reductase, and hence it is used as a treatment for prostate hypertrophy.
**CHAPTER AT A GLANCE**

The reader will be able to answer questions on the following topics:
1. Synthesis of thyroxine
2. Metabolic effect of thyroid hormones
3. Assessment of thyroid function
4. Hyperthyroidism
5. Hypothyroidism

**Iodine Metabolism**

i. Daily requirement of iodine is 150-200 micrograms/day. Its sources are drinking water, fish, cereals, vegetables and iodinated salt.

ii. Total body contains 25-30 mg of iodine. All cells do contain iodine; but 80% of the total is stored in the thyroid gland. Iodine level in blood is 5-10 microgram/dl.

iii. In most parts of the world, iodine is a scarce component of the soil. Upper regions of mountains generally contain less iodine. Such areas are called goiterous belts, e.g. Himalayan region.

iv. Commercial source of iodine is seaweeds. The program of iodination of common salt has resulted in increased availability of iodine.

v. Ingredients in foodstuffs, which prevent utilisation of iodine are called goitrogens. Goitrogens are seen in cassava, maize, millet, bamboo shoots, sweet potatoes and beans. Cabbage and tapioca contain thiocyanate, which inhibits iodine uptake by thyroid. Mustard seed contains thiourea, which inhibits iodination of thyroglobulin.

vi. The only biological role of iodine is in formation of thyroid hormones, thyroxine (T₄) and tri-iodo thyronine (T₃).

**Synthesis and Secretion of Thyroxine**

**Step 1, Uptake of Iodine**
Thyroid gland takes up and concentrates iodine (Step 1 in Fig. 47.1). This step is inhibited by thiocyanate and perchlorate, which compete for the carrier mechanism. This step is stimulated by TSH. The congenital defect, iodine trapping defect, may be treated by large doses of iodine.

**Step 2, Oxidation of Iodine**
The iodide taken up by the thyroid cell is oxidised to active iodine (Step 2 in Fig. 47.1). The thyroid is the only organ which can perform this oxidation step. This is catalyzed by the enzyme thyroperoxidase. The reaction needs hydrogen peroxide, which is produced by an NADPH-dependent reaction (Fig. 47.2). The NADPH is generated by the hexose monophosphate shunt pathway. This second step is stimulated by TSH and inhibited by antithyroid drugs such as thiourea, thiouracil and methimazole (Fig. 47.3). In patients with an inborn error of iodide oxidation defect, treatment is T₄ administration.
Step 3, Iodination
Then thyroglobulin (Tgb) is iodinated. Thyroglobulin is synthesized by the thyroid follicular cells. It is a large protein with about 5000 amino acids (660 kD). It contains about 10% carbohydrates. There are 115 tyrosine residues in the Tgb, out of which 35 residues can be iodinated. Iodination of the tyrosine is taking place on the intact Tgb molecule in the follicular space. Thus mono-iodo tyrosine (MIT) and di-iodo tyrosine (DIT) are produced (Fig. 47.4).

Step 4, Coupling
Some of the tyrosine residues in the thyroglobulin are aligned opposite each other, and are coupled (step 4, Fig. 47.1). When two DIT molecules couple, one molecule of tetra-iodo thyronine (T₄) is formed (Fig. 47.4). The Tri-iodo thyronine (T₃) may be formed by de-iodination of T₄. Under normal conditions, 99% of the hormone produced by the thyroid gland is T₄. The T₄ residues are now attached to the thyroglobulin molecule. The iodination and coupling are taking place in the borders of the follicular cells. The iodotyrosyl coupling defect, an inborn error, affects this 4th step. Treatment is to give T₄.

Step 5, Storage
The thyroid gland is unique, in that it is the only endocrine gland to store appreciable amounts of the hormone (Step 5 in Fig. 47.1). The thyroglobulin contains about 8 T₄ residues per molecule. It is stored as colloid in the thyroid acini.

Step 6, Utilization
When necessity arises, the thyroglobulin is taken from the acinar colloid, into the cell by pinocytosis (Step 6, Fig. 47.1).

Step 7, Hydrolysis
The T₄ is liberated by hydrolysis by specific proteases. This activity is markedly enhanced by TSH. This hydrolysis is depressed by iodide and therefore potassium iodide (KI) is used as an adjuvant in hyperthyroidism. In a genetic disorder, abnormal Tgb is synthesized, resulting in deficient proteolysis and deficiency of thyroxine.

Step 8, Release
The T₄ thus generated is released into the bloodstream. The T₃ is produced by de-iodination at 5’ position, either inside the thyroid cell or in the peripheral tissues. The reverse T₃ (rT₃) is produced by de-iodination at 5 position. Its biological activity is negligible.

Step 9, Salvage of Iodine
The MIT and DIT that are not utilised are de-iodinised and salvaged for reutilization inside the cell itself (Step 9 in Fig. 47.1). Deiodinase defect is the inborn error of metabolism affecting this step. In such cases, DIT and MIT are seen in urine. Since...
iodine is excreted, iodine deficiency is manifested. Treatment is to give iodine.

Step 10, Transport of Thyroid Hormones
Thyroid hormones are transported in plasma by proteins (Step 10 in Fig. 47.1). The bound form is biologically inactive, but they can be rapidly released. Total protein bound iodine (PBI) is about 10 microgram/dl; out of which T₄ constitutes 8 microgram/dl. The thyroxine binding globulin (TBG) (54 kD) carries about 80% of T₄ and 60% of T₃. The rest of thyroid hormones are loosely bound with Transthyretin (TTR) (prealbumin with 55 kD) and albumin (69 kD).

Step 11, Catabolism of Thyroid Hormones
T₄ has a half-life of 4-7 days, while T₃ has about 1 day. T₃ is biologically more active. T₄ is a prohormone which is de-iodinated to T₃. In the peripheral tissues, de-iodination takes place. This is done by a deiodinase, a selenium containing enzyme. Part of the T₃ and T₄ are conjugated with glucuronic acid and excreted through bile, and to a lesser extent, through urine. Deamination of T₄ produces tetraiodothyroacetic acid (Tetrac); and T₃ gives rise to tri-iodo-thyroacetic acid (Triac). These are only one-fourth as active as the parent compound.

Mechanism of Action of Thyroid Hormone
The hormone attaches to specific nuclear receptors. Then the receptor-hormone complex binds to the DNA. The T₃ receptor complex binding sequence in the DNA or the thyroid responsive element (TRE) has been identified (Table 44.3). The T₃ binding results in increase in transcription rate.

Metabolic Effects of Thyroid Hormones
i. The hormone exerts action on every cell of the body. Calorigenic effect or thermogenesis is the major effect of thyroid hormone. One mg of T₄ will produce an excess of 1000 kcal. This thermogenic effect is mediated by uncoupling of oxidative phosphorylation.
ii. Basal metabolic rate (BMR) is increased. Thyroxine increases cellular metabolism.
iii. Earliest effect of T₄ is stimulation of RNA synthesis and consequent increase in protein synthesis. Higher concentration of T₃ causes protein catabolism and negative nitrogen balance.
iv. Loss of body weight is a prominent feature of hyperthyroidism.
v. Gluconeogenesis and carbohydrate oxidation are increased. Glucose tolerance test shows rapid absorption.
vi. Fatty acid metabolism is increased. Cholesterol degradation is increased and hence cholesterol level in blood is decreased, which is another hallmark of hyperthyroidism.

Theft Function Tests
1. Assay of hormones
i. Measurement of T₄ and T₃ levels in blood by RIA (radio immuno assay) or by ELISA form the basis of laboratory diagnosis of thyroid diseases. Principles of these methods are described in Chapter 54. Advanced techniques are chemiluminiscence and immunofluorescence; these also utilize antibodies for the assay technique.
ii. In hyperthyroidism, thyroid hormone levels are increased. Both T₃ and T₄ levels are increased, while TSH is reduced due to feedback inhibition.
iii. In hypothyroidism, T₃ and T₄ are reduced; but TSH levels are increased due to lack of feedback effect.
iv. But when hypothyroidism is due to hypothalamic or pituitary defect, then TSH, T₃ and T₄, all are decreased.

2. Free T₃ and T₄
The free hormones are the really active molecules. Nowadays, very sensitive ELISA techniques are available to quantitate this free fraction. The values of free hormones are not affected by the amount of carrier proteins in the blood.

3. Binding proteins
Availability of the assay of free hormone has made this test only of historical importance. The abnormalities in the level of binding proteins may be reflected as abnormal hormone
6. Cholesterol
In hypothyroidism, cholesterol level in blood is increased. It is not diagnostic, because hypercholesterolemia is seen not only in hypothyroidism, but also in diabetes mellitus, hypertension, obstructive jaundice and nephrotic syndrome. However, cholesterol level is a useful index in monitoring the effectiveness of the therapy in thyroid conditions. Cholesterol level is increased in hypothyroidism, because cholesterol carrying lipoprotein degradation is decreased.

7. Radioactive iodine uptake (RAIU)
Radioactive Iodine uptake by thyroid gland and thyroid scanning with Tc99 (radioactive technicium) are of diagnostic value (Chapter 53). These tests are contraindicated in pregnancy and childhood.

8. Detection of thyroid antibodies
In Grave’s disease, the presence of thyroid stimulating immunoglobulin (TSIg), also known as long acting thyroid stimulator (LATS) is seen in circulation. The LATS can bind to TSH receptors on thyroid gland and produce stimulation which is not under feedback control. The TSIg is an antibody generated against the TSH receptor.

In Hashimoto’s thyroiditis antimicrosomal antibodies, antithyroglobulin antibodies, and antinuclear antibodies are detected in the circulation. They produce cell destruction and eventual hypothyroidism.

Abnormalities of Thyroid Function
In 1835 Robert James Graves and in 1840 Carl Adolph Basedow described the hyperthyroidism (Graves-Basedow disease). In 1915 Kendall (Nobel prize, 1950), isolated thyroxin. Emil Kocher was the first surgeon to excise thyroid gland to treat goiter in 1883. For his contributions in thyroid pathology he was awarded Nobel prize in 1909. Diseases of the thyroid are the most common afflictions involving the endocrine systems. The commonest types of thyroid diseases are hyperthyroidism (excess secretion), hypothyroidism (decreased secretion) and goiter (enlargement of thyroid gland). Goiter may or may not be associated with abnormal function, e.g. euthyroid goiter (diffuse enlargement); nodular goiter which may lead to hyperfunction, or iodine deficiency goiter which may result in hypothyroidism.

Hyperthyroidism
i. Hyperthyroidism may be due to:
   a. increase in binding protein;
   b. increased affinity of binding protein;
   c. effects of autoantibodies;
d. TSH secreting tumors;
e. $T_4$ toxicosis ($T_4$ increase; $T_3$ low).

ii. Patients have an increased rate of metabolism, weight loss, tachycardia, fine tremors, sweating, diarrhea, emotional disturbances, anxiety and sensitivity to heat.

iii. Common causes for hyperthyroidism are:
   a. Graves' disease
   b. toxic goiter
   c. excess intake of thyroid hormones
   d. Rarely TSH secreting tumours of pituitary can lead to hyperthyroidism. Table 47.2 summarises the laboratory findings in common types of hyperthyroidism.

iv. **Secondary hyperthyroidism** is due to diseases of pituitary or hypothalamus. It is seen in TSH secreting pituitary adenoma, thyroid hormone resistance syndrome, chorionic gonadotropin secreting tumors and in gestational thyrotoxicosis.

v. **Primary hyperthyroidism** is due to diseases of thyroid gland. It is seen in Graves' disease, toxic multinodular goiter, toxic adenoma, functioning metastatic thyroid carcinoma, TSH receptor mutation, Struma ovarii (teratomas of ovary), iodine excess.

**Hypothyroidism**

i. **Primary hypothyroidism** is due to diseases of thyroid gland. It is seen in autoimmune hypothyroidism (e.g. Hashimoto's thyroiditis), thyroidectomy and radiation therapy. Drugs producing hypothyroidism are Lithium, anti-thyroid drugs and para aminosalicylic acid. Congenital hypothyroidism is seen in iodine deficiency, absent or ectopic thyroid gland, dyshormonogenesis and in TSH receptor mutation.

ii. **Secondary hypothyroidism** is due to diseases of Pituitary or Hypothalamus. Hypopituitarism is caused by tumors, pituitary surgery or irradiation, infiltration, Sheehan's syndrome and isolated TSH deficiency. Hypothalamic diseases causing secondary hypothyroidism are tumors, trauma and infiltration. The measurement of TSH level and TRH test will help to differentiate these two different types (Table 47.3).

iii. Most common cause is primary thyroid disease, often seen in autoimmune thyroiditis, leading to myxedema in adults. Women are more affected than males. Symptoms are lethargy, tolerance to heat, cold intolerance, slow heart rate, weight gain, dry coarse skin, slow responses and sluggishness.

iv. In children, hypothyroidism produces mental and physical retardation, known as cretinism. The TBG may be elevated due to maternal hyperestrogenism and therefore total $T_4$ and $T_3$ may be normal. The lack of feedback will give elevated TSH level also. Prompt diagnosis and treatment are important in cretinism since any delay in starting replacement may lead to irreversible damage. Maternal hypothyroidism may also cause neonatal cretinism.

**Euthyroid goiter**
Iodine deficiency may lead to euthyroid goiter. There is raised TSH level which would produce continued stimulation of gland leading to hyperplasia and goiter. Hormone levels are seen in the lower limits of the normal values.

**Nonthyroidal illness**
When thyroid hormones are measured in acutely ill patients, $T_3$, $T_4$ and TSH are found to be lowered. These values are not reliable and referred to as non thyroidal illness. Therefore, it is advisable to defer the assessment of thyroid function in acutely ill patients till they recover completely in order to get a correct picture of the functional status of the thyroid gland.

**Related topics**
Insulin and glucagon (Chapter 24); adrenalin and noradrenalin (Chapter 17); renin, angiotensin (Chapter 30); calcitriol (Chapter 33); parathyroid hormone and calcitonin (Chapter 35).
CHAPTER AT A GLANCE

The reader will be able to answer questions on the following topics:
1. Signal molecules produced at specific sites
2. Peptide hormones regulating digestion
3. Peptide hormones regulating appetite
4. Adipose tissue derived hormones
5. Growth factors

The modern definition of a hormone is that it is synthesized by one type of cells and transported through blood to act on another type of cells. There are hundreds of polypeptides that come under this category; an exhaustive survey of all of them is out of the objective of this textbook. These are local hormones, or signal molecules produced at the local sites, and therefore are generally called as “factors”. Some important ones are described below.

Hormones Regulating Digestion of Food
The gastrointestinal peptide hormones are synthesized and secreted in the gastrointestinal tract. Their action is mainly on gastrointestinal secretions, digestion and absorption of nutrients and food intake. These gut hormones are Gastrin group (Gastrin, Cholecystokinin); Secretin like peptides (Secretin, Vasoactive intestinal polypeptide, Glucagon, GLP-1, GLP-2, Glicentin, GIP); Pancreatic polypeptide group of hormones (Pancreatic polypeptide, Neuropeptide Y), Gaunylin, Serotonin. These gastrointestinal hormones are secreted by epithelial endocrine cells. Most of them are small peptides. They regulate the rate of secretion and composition of digestive juices. They are derived from a common precursor peptide and show sequence homology especially at the C terminal fragment.

Peptide Hormones Regulating Food Intake
The discovery of a group of peptides secreted by the GIT which influences food intake has led to the understanding of the relation between hunger and satiety signals in the genesis of obesity. The major peptides included in this group are Gherlin, GIP, Somatostatin, Neuropeptide Y and Glucagon like peptide (GLP). These are described in the alphabetical order. The neuroendocrine control of intake of metabolism of nutrients protects a person against starvation and extreme obesity. Upon the entry of nutrients into the small intestine, nutrient sensing mechanisms are activated to allow the body to adapt appropriately to the incoming nutrients. There is an upper intestinal lipid-induced gut-brain neuronal axis to regulate energy homeostasis. See also discussion on regulators of appetite, in Chapter 36.

Adipose Tissue Derived Hormones
These include peptide hormones like Leptin, Adiponectin and Resistin that can regulate the energy intake, storage and metabolism. Initially, these were called as adipokines (mediators of endothelial function and inflammation involved in atherosclerosis), but presently they are often referred to as adipose tissue derived hormones.

Growth Factors
There are many regulatory factors described in literature. Since a complete classification of them is not possible, for convenience sake, they are described in the alphabetical order. Cytokines and lymphokines are briefly described in Chapter 49; Growth factors in Chapter 51, Prostaglandins in Chapter 13 and Nitric oxide in Chapter 16.

Adiponectin
It is an adipokines; a peptide with 224 amino acids. It is produced exclusively by adipose tissue. The circulating adiponectin has pronounced effects on the metabolism of both carbohydrates and lipids in liver and muscle. It promotes the uptake and oxidation of fatty acids by myocytes, but blocks the synthesis of fatty acids and gluconeogenesis by hepatocytes. At the same time, uptake and metabolism of glucose by muscle and liver are favored. The effects are exerted through an AMP mediated kinase (AMPK) that can phosphorylate several target proteins, thus affecting metabolic pathways. Net effect is to increase the sensitivity to insulin, to
promote fatty acid oxidation and improve the glucose tolerance. Levels of the hormone are inversely correlated with body fat percentage. The hormone plays a role in the suppression of the metabolic derangements that may result in type 2 diabetes, obesity, atherosclerosis and non-alcoholic fatty liver disease (NAFLD). The plasma level of adiponectin parallels with the HDL level. Low levels of both are seen in metabolic syndrome and diabetes mellitus. Thiazolidine drugs have been found to increase the adiponectin levels that can modify the sensitivity of target cells to insulin. Decreased adiponectin is associated with polycystic ovary syndrome (PCOS) independent of body mass index.

Bile Acids
In the past, bile acids were considered to be just detergent molecules derived from cholesterol in the liver. They were known to be important for the solubilization of cholesterol in the gallbladder and for stimulating the absorption of cholesterol, fat-soluble vitamins, and lipids from the intestines. However, during the last two decades, it has been discovered that bile acids are regulatory molecules. Bile acids have been discovered to activate specific nuclear receptors (farnesoid X receptor, pregnane X receptor, and vitamin D receptor), G protein coupled receptor TGR5 (TGR5), and cell signaling pathways (c-jun N-terminal kinase 1/2, AKT, and ERK 1/2) in cells in the liver and gastrointestinal tract. Bile acids appear to function as nutrient signaling molecules primarily during the feed/fast cycle as there is a flux of these molecules returning from the intestines to the liver following a meal. Bile acid-controlled signaling pathways are promising novel drug targets to treat common metabolic diseases, such as obesity, type II diabetes, hyperlipidemia and atherosclerosis.

Cadherins
Short form for calcium dependent adhesion molecules. They are transmembrane proteins. They play important roles in cell adhesion, ensuring that cells within tissues are bound together. They are dependent on calcium (Ca^{2+}) ions for their function, hence the name. The cadherin superfamily includes cadherins, protocadherins, desmogleins, and desmocollins. E-cadherins are found in epithelial tissue; N-cadherins are found in neurons; and P-cadherins are found in the placenta. In epithelial cells, E-cadherin-containing cell-to-cell junctions are often adjacent to actin-containing filaments of the cytoskeleton. Loss of E-cadherin has been implicated in cancer progression and metastasis. E-cadherin downregulation decreases the strength of cellular adhesion within a tissue, resulting in an increase in cellular motility. This, in turn, may allow cancer cells to cross the basement membrane and invade surrounding tissues.

Cholecystokinin (CCK)
Formerly called as pancreozymin, this peptide hormone is secreted by C cells of duodenum and jejunum and has 33 amino acids. The major effect is on stimulation of gallbladder contraction and secretion of bile. It decreases appetite. The main stimulus is the ingestion of food containing lipids. CCK also stimulates the secretion of pancreatic enzymes. The sulfated tyrosine residues present in gastrin and CCK increase their potency.

c-Jun
The c-Jun knockout is lethal. The c-jun produces the c-Jun protein which binds with Fos; hence c-jun protein is also called as Fos-binding protein or p39. The c-Jun in combination with c-Fos, forms the AP-1 "early response transcription factor". It is activated through double phosphorylation by the JNK pathway. This gene is intronless and is mapped to 1p32-p31, a chromosomal region involved in both translocations and deletions in human malignancies. For c-Jun N-terminal kinases (JNKs), see under JNKs.

c-Kit (CD117)
Also called KIT or c-kit receptor; it is a cytokine receptor expressed on the surface of hematopoietic stem cells as well as other cell types. This receptor binds to the stem cell factor. Mutations in this gene are associated with various cancers such as gastrointestinal stromal tumors, mast cell disease, chronic myelogenous leukemia and seminomas. The CD117 is a proto-oncogene, meaning that overexpression or mutations of this protein can lead to cancer.

Epidermal Growth Factor Receptor (EGFR)
Also called ErbB-1, (HER1 in humans), it is the cell-surface receptor which binds extracellular protein ligands. The epidermal growth factor receptor is a member of the ErbB family of receptors, a subfamily of four closely related receptor tyrosine kinases; namely, EGFR (ErbB-1), HER2/c-neu (ErbB-2), Her 3 (ErbB-3) and Her 4 (ErbB-4). Mutations affecting EGFR could result in cancers, including lung cancer, large intestinal cancers and glioblastoma multiforme. In this latter case a more or less specific mutation of EGFR, called EGFR VIII is often observed. Mutations of EGFR are implicated in about 30% of all epithelial cancers. The identification of EGFR as an oncogene has led to the development of anticancer antibodies, directed against EGFR, including gefitinib and erlotinib for lung cancer, and cetuximab for colon cancer. Other monoclonal antibodies in clinical development are zalutumumab, nimotuzumab, and matuzumab. Gefitinib, erlotinib, and lapatinib (mixed EGFR and ErbB2 inhibitor) are examples of small molecule kinase inhibitors.

Erythropoietin (EPO)
Otherwise called hematopoietin or hemopoietin, it is a glycoprotein hormone that controls erythropoiesis, or red blood cell production. It is a cytokine for erythrocyte-precursors in the bone marrow. It is produced by the peritubular capillary endothelial cells in the kidney. It also plays an important role in the brain’s response to neuronal injury. EPO is also involved in the wound healing process. Erythropoietin is available as a therapeutic agent produced by recombinant DNA technology in mammalian cell culture. It is used in treating anemia resulting from chronic kidney disease and myelosuppression induced by chemotherapy or radiation.

ERK
The MAPK/ERK pathway is a signal transduction pathway that couples intracellular responses to the binding of growth
factors to cell surface receptors. Activation of this pathway promotes cell division. The kinase cascade is relevant to many cancers, e.g. Hodgkin disease. The first drug licensed to act on this pathway is sorafenib - a Raf kinase inhibitor.

**Fibroblast Growth Factor (FGF)**

The beta-FGF is found in almost all tissues of mesodermal and neuroectodermal origin and also in tumors derived from these tissues. It is important for cell growth and differentiation. Beta-FGF stimulates the growth of fibroblasts, myoblasts, osteoblasts, neuronal cells, endothelial cells, keratinocytes and chondrocytes. In capillary endothelial cells, beta-FGF acts in an autocrine manner. The mitogenic action of beta-FGF for endothelial cells can be potentiated by thrombin, transferrin and HDL. The beta-FGF promotes the maturation and maintenance of cholinergic neurons and acts as a mitogen for chromaffin cells. It also influences the proliferation, differentiation, and function of astrocytes and oligodendrocytes.

**Gastric Inhibitory Polypeptide (GIP)**

The new name is glucose dependent insulinotropic polypeptide. It has 42 amino acids. It is secreted by the neuroendocrine K cells of the duodenum and proximal jejunum. It increases glucose-mediated insulin release and inhibits gastrin production. The hormone regulates glucose and lipid metabolism by increasing the release of insulin through an incretin effect. The secretion is stimulated by oral intake of food especially LCFA. Intestinal motility is reduced, but fluid and electrolyte secretions are stimulated.

**Gastrin**

It is secreted by G cells of antral mucosa of the stomach and proximal part of duodenum. It can exist in 3 forms, big gastrin with 34 amino acids (G-34) that is cleaved to give little gastrin with 17 amino acids (G-17) and minigastrin (G-14). G-17, produced by antral mucosa has a half-life of only 5 minutes, and is the main form. The biologically active portion of gastrin is the C terminal pentapeptide which is also available as a synthetic peptide, called penta gastrin. The major effect of gastrin is stimulation of HCl secretion. Normally gastrin secretion is under feedback control depending on the pH of gastric juice. Gastrin secretion is stimulated by high pH, proteins in stomach and central vagal stimulation. Excessive gastrin secretion occurs when gastrin producing tumors are present. This condition is referred to as Zollinger-Ellison syndrome, resulting in very high levels of acidity and chronic gastric ulcers. Adult reference value is 25-90 picogram /ml. Gastrin is stimulation of HCl secretion. Normally gastrin secretion is under feedback control depending on the pH of gastric juice. Gastrin secretion is stimulated by high pH, proteins in stomach and central vagal stimulation. Excessive gastrin secretion occurs when gastrin producing tumors are present. This condition is referred to as Zollinger-Ellison syndrome, resulting in very high levels of acidity and chronic gastric ulcers. Adult reference value is 25-90 picogram /ml.

**Ghrelin**

A short peptide hormone (28 amino acids) secreted by oxyntic cells of stomach and duodenum. It increases appetite, and decreases insulin secretion. It is a hunger signal effective between meals. It is secreted under conditions of fasting. Ghrelin has receptors in pituitary (to stimulate growth hormone production) and hypothalamus (to regulate appetite). The level is high before a meal but falls rapidly after taking food. Patients with Prader-Willi syndrome have been found to have high levels of Ghrelin that may account for excessive food intake and obesity in these patients. See also discussion on Ghrelin in Chapter 36.

**Glucagon Like Peptides (GLP)**

Insulin production is 70% greater when glucose is administered orally than when similar blood concentrations were reached after intravenous administration of glucose; this increment is due to intestinal factors, termed incretins. The most important incretins are GLP1 and GIP. GLP1 and GLP2 are both secreted by enteroendocrine L cells in ileum, colon and central nervous system. GLP1 secretion is dependent on the presence of nutrients in the lumen of small intestine. It has an inhibitory effect on glucagon secretion and enhances glucose utilization after meals by stimulating insulin secretion. The incretin effect is by acting through second messengers in the beta cells to increase the sensitivity of these cells. GLP decreases food intake and its secretion is affected by oral ingestion of nutrients and vagal stimulation. Somatostatin has an inhibitory effect on GLP secretion. GLP is a good target for treating diabetes mellitus. GLP has a half-life of about 90 seconds, and newer drugs are being developed to increase the half-life to a few days.

**Glycogen Synthase Kinase 3 (GSK 3)**

GSK 3 alpha and GSK 3 beta are serine/threonine protein kinases, that mediate the addition of phosphate molecules on serine and threonine in specific cellular substrates. GSK-3 is known for phosphorylating and thus inactivating glycogen synthase. It has also been implicated in the control of cellular response to damaged DNA. Its role as an NFKAT kinase also places it as a key regulator of both differentiation and cellular proliferation. GSK-3 can be inhibited by Akt phosphorylation, which is part of insulin signal transduction. Therefore, Akt is an activator of many of the signaling pathways blocked by GSK-3. For example, in the setting of induced Akt signaling, it can be shown that NFAT is dephosphorylated. This inhibition of GSK-3 is currently believed to underlie the therapeutic usefulness of lithium salts for the treatment of mood disorders. Furthermore, cytokine-dependent GSK-3 phosphorylation in hemopoietic cells may regulate growth.

**Granulocyte Colony Stimulating Factor (GCSF)**

GCSF is also known as colony-stimulating factor 3 (CSF 3). It is a glycoprotein, growth factor or cytokine produced by different tissues. GCSF then stimulates the bone marrow to release them into the blood. It also stimulates the survival, proliferation, differentiation and function of neutrophil precursors. The GCSF-receptor is present on precursor cells in the bone marrow, and, in response to stimulation by GCSF, initiates proliferation and differentiation into mature granulocytes. GCSF can also act on neuronal cells as a neurotrophic factor. Indeed, its receptor is expressed by neurons in the brain and spinal cord. The action of GCSF in
the central nervous system is to induce neurogenesis, to increase the neuroplasticity and to counteract apoptosis. These properties are currently under investigations for the development of treatment of neurological diseases such as cerebral ischemia. A recombinant GCSF is used in cancer patients to accelerate recovery from neutropenia after chemotherapy, allowing higher-intensity treatment regimens.

**Granulocyte Macrophage Colony Stimulating Factor**
GMCSF is a protein secreted by macrophages, T cells, mast cells, endothelial cells and fibroblasts. GMCSF is a cytokine that functions as a white blood cell growth factor. GMCSF stimulates stem cells to produce granulocytes (neutrophils, eosinophils, and basophils) and monocytes. Monocytes exit the circulation and migrate into tissue, whereupon they mature into macrophages. Activation of a small number of macrophages can rapidly lead to an increase in their numbers, a process crucial for fighting infection. GMCSF is used as a medication to stimulate the production of white blood cells following chemotherapy. It has also recently been evaluated in clinical trials for its potential as an adjuvant in HIV-infected patients.

**Heat Shock Proteins (HSP)**
They are a class of functionally related proteins whose expression is increased when cells are exposed to elevated temperatures or other stress. The dramatic upregulation of the heat shock proteins is a key part of the **heat shock response**. Heat-shock proteins are named according to their molecular weight. For example, Hsp60, Hsp70 and Hsp90 refer to families of heat shock proteins on the order of 60, 70 and 90 kilodaltons in size, respectively. The small 8 kilodalton protein ubiquitin, which marks proteins for degradation, also has features of a heat shock protein. Functions of HSP include in (1) upregulation in stress, (2) role as chaperone, (3) housekeeping, (4) cardiovascular role, and (5) immunity.

**Hepatocyte Growth Factor (HGF) and HGF Receptor (HGFR)**
Also called MET (mesenchymal epithelial transition factor). It is a proto-oncogene. Hepatocyte growth factor regulates cell growth, cell motility, and morphogenesis by activating a tyrosine kinase signaling cascade after binding to the proto-oncogenic c-Met receptor. Hepatocyte growth factor is secreted by mesenchymal cells and acts as a multi-functional cytokine on cells of mainly epithelial origin. MET is a membrane receptor that is essential for embryonic development and wound healing. Hepatocyte growth factor (HGF) is the only known ligand of the MET receptor. MET is normally expressed by cells of epithelial origin, while expression of HGF is restricted to cells of mesenchymal origin. Upon HGF stimulation, MET induces several biological responses that collectively give rise to invasive growth. Abnormal MET activation in cancer correlates with poor prognosis. Active MET triggers tumor growth, formation of new blood vessels (angiogenesis) that supply the tumor with nutrients, and cancer spread to other organs (metastasis). MET is deregulated in many types of human malignancies, including cancers of kidney, liver, stomach, breast, and brain. Normally, only stem cells and progenitor cells express MET, which allows these cells to grow invasively in order to generate new tissues in an embryo or regenerate damaged tissues in an adult. However, cancer stem cells are thought to hijack the ability of normal stem cells to express MET, and thus become the cause of cancer persistence and spread to other sites in the body.

**HER2/neu**
Also known as ErbB-2, which stands for “Human Epidermal growth factor receptor 2” and is a protein giving higher aggressiveness in breast cancers. HER2 is a cell membrane surface-bound receptor tyrosine kinase and is normally involved in the signal transduction pathways leading to cell growth and differentiation. It is encoded within the genome by HER2/neu, a known proto-oncogene. Approximately 15-20 percent of breast cancers have an amplification of the HER2/neu gene or overexpression of its protein product, leading to increased disease recurrence and worse prognosis. Because of its prognostic role as well as its ability to predict response to trastuzumab (Herceptin), breast tumors are routinely checked for overexpression of HER2/neu. Overexpression also occurs in other cancer such as ovarian cancer, stomach cancer, and aggressive forms of uterine cancer.

**HMGB (High Mobility Group Box Protein)**
Originally known as amphoterin, it mediates neural growth and binds receptors for advanced glycation end products (RAGE). HMGB1 has 219 amino acid residues. It is located in the nucleus. It is a chromatin-associated nuclear protein that plays an important role in transcription and DNA recombination. It plays a critical role in HIV, sepsis, tumors, cardiovascular diseases, neurologic disorders and amyloidosis.

**Hypoxia Inducible Factors (HIFs)**
HIFs are transcription factors that respond to changes in available oxygen in the cellular environment, specifically, to decrease in oxygen, or hypoxia. Hypoxia promotes the formation of blood vessels, and is important for the formation of a vascular system in embryos. The hypoxia in wounds promotes the formation of blood vessels, but also the migration of keratinocytes and the restoration of the epithelium. In general, HIFs are vital to development.

**ICAM**
It is the intercellular adhesion molecule, present in low concentrations on the membranes of leukocytes and endothelial cells. Upon cytokine stimulation, the concentrations greatly increase. It stabilizes cell to cell interactions and facilitates leukocyte endothelial transmigration. ICAM-1 has been characterized as a site for the cellular entry of human rhinovirus. ICAM-1 possesses binding sites for a number of immune-associated ligands. Notably, ICAM-1 binds to Macrophage Adhesion Ligand-1 (Mac-1), Leukocyte Function Associated Antigen-1 (LFA-1), and Fibrinogen. These three proteins are generally expressed on endothelial cells and leukocytes, and they bind to ICAM-1 to facilitate transmigration of leukocytes across vascular endothelia during the inflammatory response.
**Insulin-like Growth Factor (IGF)**
Secreted by hepatocytes, it produces hypoglycemia. It mediates some actions of growth hormone.

**Insulin-like Growth Factor Receptor (IGFR)**
It is a transmembrane receptor that is activated by IGF1 and IGF2. It belongs to the large class of tyrosine kinase receptors. IGF-1 plays an important role in growth and continues to have anabolic effects in adults. It can induce hypertrophy of skeletal muscle and other target tissues. The IGFR is implicated in several cancers, including breast and prostate cancers. It has a role in insulin signaling and on the normal aging process as well.

**Insulin Receptor (IR)**
Insulin binds to its receptor which, in turn, starts many protein activation cascades. These include: translocation of Glut-4 transporter to the plasma membrane and influx of glucose, glycogen synthesis, glycolysis and fatty acid synthesis. The main effect of activation of the insulin receptor is increased glucose uptake. For this reason “insulin insensitivity”, or a decrease in insulin receptor signaling, leads to diabetes mellitus type 2. The alpha and beta subunits of the IR are encoded by a single gene (INSR). The insulin receptor has also recently been designated as CD220 (cluster of differentiation 220). (See Chapter 24).

**Insulin Receptor Substrate (IRS)**
IRS is an important ligand in the insulin response of human cells. IRS1 plays a key role in transmitting signals from the insulin receptors to intracellular pathways PI3K/Akt and Erk MAP kinase pathways. IRS-1 plays important biological function for both metabolic and mitogenic pathways. Mice deficient of IRS1 have pronounced growth impairment. IRS1 may also play a role in breast cancer (See chapters 24 and 44).

**Interferons (IFNs)**
IFN (alpha, beta, gamma) are proteins made and released by the cells of most vertebrates in response to the presence of pathogens — such as viruses, bacteria, or parasites — or tumor cells. They allow communication between cells to trigger the protective defenses of the immune system that eradicate pathogens or tumors. IFNs belong to the large class of glycoproteins known as cytokines. Although they are named after their ability to “interfere” with viral replication within host cells, IFNs have other functions: they activate immune cells, such as natural killer cells and macrophages; they increase recognition of infection or tumor cells by up-regulating antigen presentation to T lymphocytes; and they increase the ability of uninfected host cells to resist new infection by virus. Certain host symptoms, such as aching muscles and fever, are related to the production of IFNs during infection. About ten distinct IFNs have been identified in mammals; seven of these have been described for humans. They are typically divided among three IFN classes: Type I IFN, Type II IFN, and Type III IFN. IFNs belonging to all IFN classes are very important for fighting viral infections. All interferons share several common effects; they are antiviral agents and can fight tumors. Another function of interferon is to upregulate major histocompatibility complex molecules, MHC I and MHC II, and increase immunoproteasome activity. The immune effects of interferons have been exploited to treat several diseases, e.g. actinic keratosis, superficial basal cell carcinoma, papilloma and external genital warts. Synthetic IFNs are also made, and administered as antiviral, antiseptic and anticarcinogenic drugs, and to treat some autoimmune diseases. Interferon beta-1a and interferon beta-1b are used to treat and control multiple sclerosis. This treatment is effective for slowing disease progression and activity in relapsing-remitting multiple sclerosis and reducing attacks in secondary progressive multiple sclerosis. Interferon therapy is used (in combination with chemotherapy and radiation) as a treatment for many cancers. This treatment is most effective for treating hematological malignancy; leukemia and lymphomas including hairy cell leukemia, chronic myeloid leukemia, nodular lymphoma, cutaneous T-cell lymphoma. Patients with recurrent melanomas receive recombinant IFN-á2b. Both hepatitis B and hepatitis C are treated with IFN-á, often in combination with other antiviral drugs.

**Jun N-terminal kinases (JNKs)**
JNK are kinases that bind and phosphorylate c-Jun on Ser63 and Ser73. They are mitogen-activated protein kinases which are responsive to stress stimuli, such as cytokines, ultraviolet irradiation, heat shock, and osmotic shock. JNK1 is involved in apoptosis, neurodegeneration, cell differentiation, proliferation and inflammatory conditions JNK also functions in cytokine production mediated by AP-1 (Activation Protein 1). Inflammatory signals, changes in levels of reactive oxygen species, ultraviolet radiation, protein synthesis inhibitors, and a variety of stress stimuli can activate JNK.

**Leptin**
It is a 16 kDa protein, mainly produced by white adipose tissue. Leptin functions as a satiety signal. It is an index of the energy reserve in the body. When the energy reserve is adequate, leptin levels are increased which would suppress further food intake. Leptin binds to the neuropeptide Y in the arcuate nucleus and controls the intake of food by interacting with the hypothalamic centers. Neuropeptide Y is one of the major regulators of appetite and interaction with leptin has an inhibitory effect. Obesity is associated with leptin resistance and high levels of leptin in plasma. Studies with gene knock out mice have shown that the “Ob gene” produces leptin and in its absence, obesity develops. The administration of recombinant leptin is found to be effective in the control of childhood obesity. See also discussion on leptin in Chapter 36.

**Macrophage Colony Stimulating Factor (MCSF)**
A cytokine which influences hemopoietic stem cells to differentiate into macrophages. MCSF also helps to combat intercellular viral infection. It may also be involved in development of the placenta.

**Macrophage Inflammatory Proteins (MIP)**
Belongs to the family of chemotactic cytokines known as chemokines. In humans, there are two major forms,
MIP-1alpha and MIP-1beta, that are now officially named CCL3 and CCL4 respectively. Both are major factors produced by macrophages after they are stimulated with bacterial endotoxins. They activate human granulocytes (neutrophils, eosinophils and basophils) and induce the synthesis and release of other pro-inflammatory cytokines such as interleukin 1 (IL-1), IL-6 and TNF-alpha from fibroblasts and macrophages.

**MAP Kinase Activated Protein Kinase 2**
MAPKAPK2-2 is an enzyme that is encoded by the MAPKAPK2 gene. In conjunction with p38 MAP kinase, this kinase is known to be involved in many cellular processes including stress and inflammatory responses, nuclear export, gene expression regulation and cell proliferation. Heat shock protein HSP27 was shown to be one of the substrates of this kinase in vivo.

**Matrix Metalloproteinases (MMPs)**
They are zinc-dependent endopeptidases; other family members are adamalysins, serralysins, and astacin. The MMPs belong to a larger family of proteases known as the metzincin superfamily. Collectively they are capable of degrading all kinds of extracellular matrix proteins. They cleave cell surface receptors, release the apoptotic ligands (such as the FAS ligand), and inactivate chemokines/cytokines. MMPs also play a major role on cell proliferation, migration (adhesion/dispersion), differentiation, angiogenesis, apoptosis and host defense. The MMPs play an important role in tissue remodeling associated with morphogenesis, angiogenesis, tissue repair, cirrhosis, arthritis and metastasis. MMP-2 and MMP-9 are thought to be important in cancer metastasis. MMP-1 is involved in rheumatoid arthritis, osteo-arthritis and aortic aneurysm. Excess MMPs degrade the structural proteins of the aortic wall. The MMPs are inhibited by specific endogenous tissue inhibitor of metalloproteinases (TIMPs), which comprise a family of four protease inhibitors: TIMP-1, TIMP-2, TIMP-3 and TIMP-4.

**Mitogen Activated Protein Kinase Kinase**
Abbreviated as MAPKK or MAP2K, it is a kinase enzyme which phosphorylates Mitogen-activated protein kinase (MAPK). There are 7 genes — MEK 1 & 2, MKK 3 to 7. The activators of p38 (MKK3 and MKK4), JNK (MKK4), and ERK (MEK1 and MEK2) define independent MAP kinase signal transduction pathways.

**Monocyte Chemotactic Protein-1 (MCP1)**
Also known as Chemokine C-C Motif Ligand 2 (CCL2). It is a cytokine belonging to the CC chemokine family. CCL2 recruits monocytes, memory T cells, and dendritic cells to sites of tissue injury and infection. In the bone, CCL2 is expressed by mature osteoclasts and osteoblasts and is under the control of NFκB. CCL2 causes the degranulation of basophils and mast cells, an effect potentiated by pre-treatment with IL-3 and other cytokines.

**Neuropeptide Y**
It is secreted by the N cells of ileum and also those present in entire nervous system, adrenal gland and pancreas. The action is to inhibit glucose-stimulated insulin secretion. See also discussion on Neuropeptide Y in Chapter 36.

**Osteocalcin**
A noncollagenous protein found in bone and dentin. It is secreted by osteoblasts and plays a role in mineralization and calcium ion homeostasis. As osteocalcin is manufactured by osteoblasts, it is often used as a biochemical marker, or biomarker, for the bone formation process. It has been routinely observed that higher serum osteocalcin levels are relatively well correlated with increases in bone mineral density (BMD) during the treatment with anabolic bone formation drugs for osteoporosis, such as Forteo. Osteocalcin is used as a preliminary biomarker on the effectiveness of a given drug on bone formation. See Chapter 35 for calcium metabolism.

**Osteonectin**
A glycoprotein in the bone that binds calcium. It is secreted by osteoblasts during bone formation, initiating mineralization and promoting mineral crystal formation. It also shows affinity for collagen in addition to bone mineral calcium. Osteonectin also increases the production of matrix metalloproteinases, a function important to invading cancer cells within bone. Overexpression of osteonectin is reported in chronic pancreatitis and in many human cancers such as breast, prostate and colon.

**Osteopontin (OPN)**
Synonyms for this protein include sialoprotein I and 44K BPP (bone phosphoprotein). It is an important factor in bone remodeling. OPN binds to several integrin receptors expressed by leukocytes. These receptors function in cell adhesion, migration, and survival in these cells. OPN plays an important role in neutrophil recruitment. Activated T cells are promoted by IL-12 to differentiate towards the Th1 type, producing cytokines including IFN-gamma. OPN inhibits production of the Th2 cytokine IL-10, which leads to enhanced Th1 response. OPN influences cell-mediated immunity and has Th1 cytokine functions. It enhances B cell immunoglobulin production and proliferation. OPN is an important anti-apoptotic factor; it blocks the cell death of macrophages, T cells, fibroblasts and endothelial cells exposed to harmful stimuli. OPN prevents the cell death in inflammatory colitis. OPN is an active player in wound healing, bone turnover, tumorigenesis, inflammation, ischemia and immune responses. Therefore, manipulation of OPN may be useful in the treatment of autoimmune diseases, cancer metastasis, osteoporosis and some forms of stress.

**Osteoprotegerin (OPG)**
Also known as osteoclastogenesis inhibitory factor (OCIF), it is a cytokine, which can inhibit the production of osteoclasts. It is a member of the tumor necrosis factor (TNF) receptor superfamily. Osteoprotegerin inhibits the differentiation of osteoclast precursors. Osteoclasts are related to monocyte/macrophage cells and are derived from granulocyte/macrophage-forming colony units (CFU-GM)) into osteoclasts. Recombinant human osteoprotegerin acts on bone, increasing bone mineral density and bone volume. Osteoprotegerin has been used experimentally to decrease bone resorption in women with postmenopausal osteoporosis and in patients with lytic bone metastases.
p38
It is so named, because it is a protein with molecular weight 38 kDa. Mitogen activated protein kinases are a class of protein kinases which are responsive to stress stimuli, such as cytokines, ultraviolet irradiation, heat shock, and osmotic shock, and are involved in cell differentiation and apoptosis. Similar to the SAPK/JNK pathway, p38 MAP kinase is activated by a variety of cellular stresses including osmotic shock, inflammatory cytokines, lipopolysaccharides (LPS), ultraviolet light and growth factors.

p53
It is so named, because it is a protein with molecular weight 53 kDa. It is a tumor suppressor protein that in humans is encoded by the TP53 gene. The p53 regulates the cell cycle and thus functions as a tumor suppressor that is involved in preventing cancer. As such, p53 has been described as "the guardian angel gene," and the "master watchman," referring to its role in conserving stability by preventing genome mutation. It can activate DNA repair proteins when DNA has sustained damage. It can induce growth arrest by holding the cell cycle at the G1/S regulation point on DNA damage recognition. It can initiate apoptosis (programmed cell death), if the DNA damage proves to be irreparable. Activated p53 binds DNA and activates expression of several genes including WAF1/CIP1 encoding for p21. This p21(WAF1) binds to the G1-S/CDK (CDK2) and S/CDK complexes (molecules important for the G1/S transition in the cell cycle) inhibiting their activity. The p53 has many anticancer mechanisms, and plays a role in apoptosis, genetic stability, and inhibition of angiogenesis. People who inherit only one functional copy of the TP53 gene will most likely develop tumors in early adulthood, a disease known as Li-Fraumeni syndrome. The TP53 gene can also be damaged in cells by mutagens (chemicals, radiation, or viruses), increasing the likelihood that the cell will begin decontrolled division. More than 50 percent of human tumors contain a mutation or deletion of the TP53 gene. (Please also see cell cycle regulation in Chapter 42).

p70S6 kinase
The p70S6K is a serine/threonine kinase that acts downstream of PI3P and phosphoinositide-dependent kinase-1 in the PI3 kinase pathway. As the name suggests, its target substrate is the S6 ribosomal protein. Phosphorylation of S6 induces protein synthesis at the ribosome. Physical exercise activates protein synthesis via phosphorylation (activation) of p70S6K in a pathway that is dependent on mTOR. This has been demonstrated by using an inhibitor of mTOR, rapamycin, to block an increase in muscle mass. Exercise has been shown to increase levels of IGF-1 in muscle, thus inducing the IGF-1/PI3K/Akt/p70S6K signaling pathway, and thereby increasing the protein synthesis required to build muscle.

Pancreatic Polypeptide
Stimulates biliary flow and exocrine pancreatic secretion. It is produced by pancreatic PP cells. Increased levels are seen in insulinomas, gastrinomas, carcinoid tumors arising outside the pancreas, adenocarcinomas of pancreas, stomach, colon, rectum, duodenal ulcer, diabetes mellitus, MEN Type I, medullary carcinoma thyroid and Zollinger–Ellison syndrome.

Poly (ADP-ribose) Polymerase (PARP)
PARP is a protein involved in DNA repair and programmed cell death. PARP enzymes are essential in a number of cellular functions, including expression of inflammatory genes. One important function of PARP is assisting in the repair of single-strand DNA nicks. Upon DNA cleavage by enzymes involved in cell death (such as caspases), PARP can deplete the ATP of a cell in an attempt to repair the damaged DNA. ATP depletion in a cell leads to lysis and cell death. PARP also has the ability to directly induce apoptosis, via the production of PAR, which stimulates mitochondria to release AIF. This mechanism appears to be caspase-independent. PARP mediated post-translational modification of proteins such as CTCF can affect the amount of DNA methylation at CpG dinucleotides. This regulates the insulator features of CTCF that can differentially mark the copy of DNA inherited from either the maternal or paternal DNA through the process known as genomic imprinting. PARP has also been proposed to affect the amount of DNA methylation by directly binding to the DNA methyltransferase.

Prolidase
A cytosolic exopeptidase that cleaves amino-dipeptides with carboxy-terminal proline or hydroxyproline. Prolidase plays a major role in collagen turnover. Serum prolidase activity is correlated with the severity of coronary artery disease.

Protein C
It is a protein that in humans is encoded by the PROC gene. Protein C is a major physiological anticoagulant. It is a vitamin decreased levels are seen in chronic pancreatitis with exocrine insufficiency.

Phosphatidyl Inositol Glycan Biosynthesis Class F Protein
PIGF is a protein that is encoded by the PIGF gene. The protein is involved in glycosyl phosphatidyl inositol (GPI) anchor biosynthesis. The GPI-anchor is found on many blood cells and serves to anchor proteins to the cell surface. This protein and another GPI synthesis protein, PIGO, function in the transfer of ethanolamine phosphate (EtNP) to the third mannose in GPI.

Platelet Derived Growth Factor (PDGF)
Regulates cell growth and division. In particular, it plays a significant role in blood vessel formation (angiogenesis), the growth of blood vessels from already existing blood vessel tissue. Uncontrolled angiogenesis is a characteristic of cancer. PDGF plays a role in embryonic development, cell proliferation, cell migration, and angiogenesis. PDGF is required in cellular division for fibroblasts. In essence, the PDGF allows a cell to skip the G1 checkpoints in order to divide. PDGF is also known to maintain proliferation of oligodendrocyte progenitor cells. PDGF has provided a target for protein receptor antagonists to treat disease. There are 2 proteins, PDGF-A and B. They activate the mitogen-activated protein kinase (MAPK), PI-3 kinase and phospholipase (PLC) pathways; these are key downstream mediators of the PDGF signaling.

Platelet Derived Growth Factor (PDGF)
K-dependent serine protease enzyme that is activated by thrombin into **activated protein C** (APC). The activated form (with protein S and phospholipid as a cofactor) degrades Factor Va and Factor VIIIa. The activated protein C provides physiologic antithrombotic activity and exhibits both anti-inflammatory and anti-apoptotic activities. Protein C deficiency is a rare genetic disorder that predisposes to venous thrombosis and habitual abortion. If homozygous, this presents with a form of disseminated intravascular coagulation in newborns termed purpura fulminans; it is treated by replacing the defective protein C. Activated protein C resistance is the inability of protein C to cleave factors V and/or VIII. This may be hereditary or acquired. The best known and most common hereditary form is Factor V Leiden. Warfarin necrosis is acquired protein C deficiency; it is due to treatment with the vitamin K inhibitor anticoagulant warfarin. In initial stages of action, inhibition of protein C may be stronger than inhibition of the vitamin K-dependent coagulation factors (II, VII, IX and X), leading to paradoxical activation of coagulation and necrosis of skin.

**Resistin**
Resistin is a cysteine-rich protein with a molecular weight of 12 kDa. It is secreted by adipose tissue of mice and rats. In other mammals, resistin is secreted by immune and epithelial cells. It was called “resistin” because of the observed insulin resistance in mice injected with resistin. The effects are exactly opposite of the adiponectin. Resistin is found to increase the insulin resistance of tissues in obesity as well as in type 2 diabetes mellitus. Current research has linked resistin to inflammation and energy homeostasis.

**RANTES**
Also known as Chemokine (C-C motif) ligand 5 or CCL5. It is a protein which is encoded by the CCL5 gene. CCL5 is an 8kDa protein classified as a chemotactic cytokine or chemokine. CCL5 is chemotactic for T cells, eosinophils, and basophils, and plays an active role in recruiting leukocytes into inflammatory sites. With the help of particular cytokines (i.e. IL-2 and IFN gamma, that are released by T cells, CCL5 also induces the proliferation and activation of NK (natural-killer) cells to form LAK (lymphokine activated killer) cells. It is also an HIV-suppressive factor, released from CD8+ T cells. RANTES is a CC chemokine and expressed in more than 100 human diseases. RANTES expression is regulated in T lymphocytes by Kruppel like factor 13 (KLF13).

**Rb**
The retinoblastoma protein is a tumor suppressor protein that is dysfunctional in many types of cancer. One highly studied function of Rb is to prevent excessive cell growth by inhibiting cell cycle progression until a cell is ready to divide. Rb prevents the cell from replicating damaged DNA by preventing its progression along the cell cycle through G1 (first gap phase) into S (synthesis phase). In the hypophosphorylated state, pRb is active and carries out its role as tumor suppressor by inhibiting cell cycle progression. Phosphorylation inactivates Rb, during the M-to-G1 transition, Rb is progressively dephosphorylated by PP1, returning to its growth-suppressive hypophosphorylated state. (Please also see cell cycle regulation in Chapter 42).

**SAA (Serum Amyloid A)**
SAA proteins are a family of apolipoproteins associated with high-density lipoprotein (HDL) in plasma. Acute-phase serum amyloid A proteins (A-SAAs) are secreted during the acute phase of inflammation. These proteins recruit immune cells to inflammatory sites, and induce enzymes that degrade extracellular matrix. A-SAAs are implicated in several chronic inflammatory diseases, such as amyloidosis, atherosclerosis, and rheumatoid arthritis. Please also see Chapter 49, under amyloidosis.

**SAP-alpha and beta**
The accumulation of beta-amyloid in Alzheimer’s disease (AD) is only one of the results of proteolytic cleavage of amyloid precursor protein (APP). Cleavage by beta- and gamma-secretase leads to A-beta production, whereas alpha-secretase cleavage results in a soluble form, sAPP-alpha. It is released from neurons in response to electrical activity and may function in modulation of neuronal excitability, synaptic plasticity, neurite outgrowth, synaptogenesis, and cell survival. A signaling pathway involving guanosine 3’, 5’-cyclic monophosphate is activated by sAPP-alpha and modulates the activities of potassium channels, N-methyl-D-aspartate receptors, and the transcription factor NFkB. Genetic mutations or age-related metabolic changes may promote neuronal degeneration in Alzheimer’s disease by increasing production of A-beta and/or decreasing levels of neuroprotective sAPP-alpha. Proteolytic cleavage of beta-amyloid precursor protein (beta APP) by alpha-secretase results in release of one secreted form (sAPP) of APP (sAPP-alpha), whereas cleavage by beta-secretase releases a C-terminally truncated sAPP (sAPP-beta) plus amyloid beta-peptide (A-beta). APP-beta mutations are linked to some inherited forms of Alzheimer’s disease. In such cases, the levels of sAPP-alpha are reduced and levels of sAPP-beta are increased. The sAPP-alpha may play important roles in neuronal plasticity and survival, whereas A-beta can be neurotoxic. sAPP-alpha is approximately 100-fold more potent than sAPP-beta in protecting hippocampal neurons against excitotoxicity.

**Secretin**
A polypeptide having 27 amino acids released by the S cells of the small intestine in response to a low luminal pH (<5). Secretin stimulates secretion of pancreatic juice having a high bicarbonate content, that maintains the optimum pH for the action of pancreatic enzymes by neutralizing gastric HCl. It acts synergistically with CCK.

**Selectins**
They are a family of cell adhesion molecules (or CAMs). There are three subsets of selectins: E–Selectin, L–Selectin and P–Selectin. During an inflammatory response, stimuli such as histamine and thrombin cause endothelial cells to mobilize P-selectin from stores inside the cell to the cell surface. In addition, cytokines such as TNF-alpha stimulate the expression of E-selectin and additional P-selectin. The best-characterized ligand for the three selectins is P-selectin glycoprotein ligand-1 (PSGL-1), which is a mucin-type
glycoprotein expressed on all white blood cells. Selectins are tried experimentally, to kill cancer cells, and to treat osteoporosis.

Somatostatin (SS)
There are two forms; SS-14 has 14 amino acids and SS-28 has 28 amino acids. The synthetic analogue has 8 amino acids. Half-life of SS-14 is only 2 minutes; it is present in brain, pancreas; while SS-28 is seen in intestinal mucosa. SS is the main inhibitory peptide of the GI tract. It produces its effects through binding with 5G-protein-coupled SS receptors (SSTR1 to 5). SS inhibits the production of gastrin, CCK, secretin, VIP, insulin, pancreatic enzymes and secretion of electrolytes into the intestine. Somatostatinomas are rare, but may occur in pancreas or upper small intestine.

STAT
It is the abbreviation of Signal Transducers and Activator of Transcription. These proteins regulate cell growth, survival and differentiation. The transcription factors of this family are activated by the Janus Kinase (JAK). Dysregulation of this pathway is frequently observed in tumors and leads to increased angiogenesis and immunosuppression. STAT proteins play a role in maintaining immune tolerance and tumor surveillance. STAT proteins were originally described as latent cytoplasmic transcription factors that require phosphorylation for nuclear retention. The unphosphorylated STAT proteins shuttle between cytosol and the nucleus waiting for its activation signal. Once the activated transcription factors reach the nucleus they bind to consensus DNA-recognition motif called gamma activated sites (GAS) in the promoter region of cytokine inducible genes and activate transcription of these genes.

Tau proteins
Tau are microtubule-associated proteins that are abundant in neurons in the central nervous system. Phosphorylation of tau is regulated by a host of kinases. For example, PKN, which is a serine/threonine kinase. When PKN is activated, it phosphorylates tau, resulting in disruption of microtubule organization. Hyperphosphorylation of the tau protein (tau inclusions), however, can result in the self-assembly of tangles of paired helical filaments and straight filaments, which are involved in the pathogenesis of Alzheimer’s disease and other Tauopathies.

Transforming Growth Factor (TGF)
TGF-beta is a protein that controls proliferation, cellular differentiation, and other functions in most cells. It plays a role in immunity, cancer, heart disease and diabetes. TGF-beta acts as an antiproliferative factor in normal epithelial cells and at early stages of oncogenesis. Some cells secrete TGF-beta and also have receptors for TGF-beta. This is known as autocrine signaling. Cancerous cells increase their production of TGF, which also acts on surrounding cells. TGF-beta exists in three isoforms called TGF-beta1, TGF-beta2 and TGF-beta3. The TGF is part of a superfamily of proteins, which includes inhibins, activin, bone morphogenetic protein and Vg-1. TGF-beta induces apoptosis in two ways: through the SMAD pathway or through the DAXX pathway. TGF-beta is important in regulation of the immune system by CD25+ Regulatory T cell and the development of both CD25+ Regulatory T cell and Th17 cells. TGF-beta blocks the activation of lymphocytes and monocyte derived phagocytes.

Thrombopoietin
Secreted by hepatocytes, it stimulates platelet development and hematopoietic stem cells.

Thrombomodulin
Also called CD141 or BDCA-3. It is an integral membrane protein expressed on the surface of endothelial cells. In humans, thrombomodulin is encoded by the THBD gene. It is a cofactor in the thrombin-induced activation of protein C in the anticoagulant pathway by forming a 1:1 stoichiometric complex with thrombin. This raises the speed of protein C activation thousand-fold. Thrombomodulin-bound thrombin has no procoagulant effect. The TT-complex also inhibits fibrinolysis by cleaving thrombin-activatable fibrinolysis inhibitor (TAFI) into its active form.

Thrombospondin 2 (TSP2)
It inhibits angiogenesis in vitro by limiting proliferation and inducing apoptosis of endothelial cells (ECs). TSP2 can also modulate the extracellular levels of gelatinases (matrix metalloproteinases, MMPs) and potentially influence the remodeling of the extracellular matrix (ECM).

TIMP (Metallopeptidase Inhibitor)
TIMP-1, is a glycoprotein that is expressed from the several tissues of organisms. This protein is a member of the TIMP family. The glycoprotein is a natural inhibitor of the matrix metalloproteinases (MMPs), a group of peptidases involved in degradation of the extracellular matrix. Moreover, the protein is able to promote cell proliferation in a wide range of cell types, and have an anti-apoptotic function. Transcription of this gene is highly inducible in response to many cytokines and hormones. The gene is located within intron 6 of the synapsin I gene and is transcribed in the opposite direction.

Tumor Necrosis Factor Receptor (TNFR)
Otherwise known as death receptor; it is a cytokine receptor that binds tumor necrosis factor (TNF). TNF alpha is otherwise called, CD120.

Vascular Cell Adhesion Molecule (VCAM)
VCAM-1, also known as CD106, mediates the adhesion of lymphocytes, monocytes, eosinophils, and basophils to vascular endothelium. It also functions in leukocyte-endothelial cell signal transduction, and it may play a role in the development of atherosclerosis and rheumatoid arthritis. Upregulation of VCAM-1 in endothelial cells by cytokines occurs as a result of increased gene transcription (e.g. in response to Tumor necrosis factor-alpha (TNF-á) and Interleukin-1 (IL-1)) and through stabilization of Messenger RNA (mRNA) (e.g., Interleukin-4 (IL-4)). The promoter region of the VCAM-1 gene contains functional NFkB (nuclear factor-kappa B) sites. Primarily, the VCAM-1 protein is an endothelial ligand for VLA-4 (Very Late Antigen-4) of the beta1 subfamily of integrins. VCAM-1 expression has been also observed in
other cell types (e.g., smooth muscle cells). Certain melanoma cells can use VCAM-1 to adhere to the endothelium. VCAM-1 may participate in monocyte recruitment to atherosclerotic sites. As a result, VCAM-1 is a potential drug target.

**Vascular Endothelial Growth Factor (VEGF)**
VEGF is a chemical signal produced by cells that stimulates the growth of new blood vessels. VEGF is a sub-family of the platelet-derived growth factor family of cystine-knot growth factors. It is part of the system that restores the oxygen supply to tissues when blood circulation is inadequate. The normal function of VEGF is to create new blood vessels during embryonic development, after injury, and collateral circulation to bypass blocked vessels. Solid cancers cannot grow beyond a limited size without an adequate blood supply; cancers that can express VEGF are able to grow and metastasize. Drugs such as bevacizumab can inhibit VEGF and control such cancers. VEGF has been associated with breast cancer, rheumatoid arthritis, diabetic retinopathy, age related macular degeneration, angiosarcoma, etc. Anti-VEGF therapies involve monoclonal antibodies such as bevacizumab (Avastin), antibody derivatives such as ranibizumab (Lucentis), or orally available small molecules that inhibit the tyrosine kinases stimulated by VEGF: these are lapatinib (Tykerb), sunitinib (Sutent), sorafenib (Nexavar), axitinib, and pazopanib. All members of the VEGF family stimulate cellular responses by binding to tyrosine kinase receptors (VEGFRs) on the cell surface, causing them to dimerize and become activated through transphosphorylation.

**Vasoactive Intestinal Polypeptide (VIP)**
A potent secretagogue of NaCl and water in the intestine and pancreas. It is a neuropeptide released by enteric neurons that regulate electrolyte and NaCl secretion. VIP is found in highest concentrations in brain and GIT. VIP is present in the nerve fibers supplying GIT. Functions of VIP are a) neurotransmitter in the central and autonomous nervous system, b) vasodilatation and relaxation of smooth muscles of the gut, c) secretion of water and electrolytes from the pancreas and gut as well as d) release of hormones from the hypothalamus, pancreas and gut. Normal fasting value is < 50 pg /ml. It is increased in pancreatic VIP secreting tumors (VIPomas, Verner-Morrison syndrome), neural crest tumors in children (ganglio-neurblastoma), pancreatic islet cell hyperplasia, liver disease, pheochromocytoma, medullary thyroid carcinoma, MEN Type I (multiple endocrine neoplastic syndrome Type I). Tumors producing VIP (VIPomas) result in a triad of symptoms; watery diarrhea, hypokalemia and achlorhydria; this is referred to as pancreatic cholera (WDHA syndrome).
Immunology is one of the rapidly advancing branches of medical science. Smallpox has been completely eradicated from the world by 1985; this is a triumph of immunology. Three salient features of immunological reactions are: Recognition of self from nonself or foreign substances; specificity of the reactions, and memory of the response.

When injected with 100 different proteins, the animal will produce 100 different antibodies; this is called specificity. If a person belongs to A group antigen of RBC, antibodies against B group are seen in circulation. There is an extra N-acetyl group in antigen A; this is the only molecular difference between A and B antigens. Immune system is exquisitely specific to recognize even this small difference at molecular level. If the same antigen is introduced for a second time, body will react immediately; this memory is the basis of vaccination.

Introduction of cowpox vaccination by Jenner in 1798 paved the foundation for immunization procedures. This does not mean that he had discovered the procedure. For 10 years, he was in Punjab, India as a doctor, when he came to know about the inoculation procedure available throughout India from time immemorial. Jenner has developed and simplified the procedure. Rabies vaccine was discovered by Pasteur in 1881. Emil von Behring (Nobel prize, 1901) introduced therapy with antibodies, especially against diphtheria. In 1908, Nobel prize was awarded to Paul Ehrlich for explaining the antibody production and to Metchnikov for discovery of phagocytosis. Life saving blood transfusion was made possible by the pioneering work on human blood groups, the ABO and Rh system by Karl Landsteiner (Nobel prize, 1930). By employing specific antibodies, nanogram or picogram quantities of biologically important substances can be estimated. This is termed as radioimmunoassay (Chapter 54). Radioimmunoassay was first described by Rosalyn Yalow (Nobel prize, 1977).

**Antigens**

Certain components of the cell membranes act as specific antigens. They will be different from person-to-person in their chemical composition and three dimensional structure. Hence, the immunocompetent cells could recognise the self from nonself. Any substance which invokes an immunological response is an antigen or immunogen. Antibody response will usually be selective against specific spatial configurations on the antigen, which are called antigenic determinant sites, known as epitopes.
Immune Response
The lymphocytes generated from the bone marrow, passed through and processed by the thymus gland, are then called T lymphocytes. They can directly kill the target cells and are the effector cells for the cell-mediated immunity (CMI). The T lymphocytes are found mainly in the paracortical areas of lymph nodes and periarteriolar sheaths in the spleen. In peripheral blood 80% lymphocytes are T cells, and 15% are B cells.

Certain other cells originated from bone marrow and processed by the Bursa of Fabricius in avians, are called B cells. The Bursa equivalent organs in human beings are gut associated (including Peyer's patches) and lung associated lymphoid organs. Immunoglobulins are secreted by plasma cells belonging to the B lymphocytes. The B cells govern the humoral immunity.

Clonal Selection: Immunoglobulins of different specificity are available on the B cell surface. When an antigen is introduced, the antigen selects out that particular cell carrying the specific antibody. This results in a series of divisions of that cell and a clone of cells are produced. These cells are finally differentiated into plasma cells. This is the antigen dependent clonal selection. A particular clone of cells secretes antibodies of the same specificity.

Effector Mechanisms
The following are the immunological effector mechanisms by which foreign cells are destroyed or particles are removed:

1. Cell Mediated Immunity
The following are the major activities of T lymphocytes.
A. Immunity against infections: T cells mediate effective immunity against bacteria such as mycobacteria, many viruses and almost all parasites.
B. Rejection of allograft: When an organ (heart, kidney) is transplanted from one person to another, it is called allograft. Body tries to reject such transplanted organs, mainly by T cell mediated mechanism.
C. Tumor cell destruction: Although other mechanisms are also involved in killing tumor cells, T cell activity is the predominant one.
D. Helper function: T helper (TH) cells are a subgroup of cells which carry CD4 determinants on the cell surface (CD = cluster determinant). They are necessary for optimal antibody production by plasma cells and for generation of cytotoxic T cells. They are selectively destroyed in AIDS (Chapter 50).
E. Suppressor function: T suppressor (TS) cells are CD8 positive cells. They downregulate the activities of both T and B cells.
F. Production of lymphokines: T cells when stimulated by antigens, liberate many soluble substances called cytokines or lymphokines. They are described at the end of this Chapter.
G. Delayed type hypersensitivity: When tuberculin (antigen prepared from tubercle bacilli) is injected intradermally in a patient with tuberculosis, an erythematous indurated lesion develops slowly reaching its maximum within 48-72 hours. This is called delayed type hypersensitivity. Hypersensitivity is the over-reaction of the immune system, often resulting in unwanted tissue destruction. This is responsible for caseation and lung cavity formation in the case of tuberculosis, granulomatous skin lesions in tuberculoid leprosy, skin lesions in herpes simplex and contact hypersensitivity to chemicals and plant products.

2. Humoral Immunity
Antibodies are produced by plasma cells. These are immunoglobulins, described in detail below. The antigen-antibody reaction leads to activation of complement system, which destroys the foreign cells. The antibodies can destroy the target cells by the following mechanisms: (1) Classical complement pathway. (2) Antibody dependent cell mediated cytotoxicity (described below). (3) Agglutination. (4) Opsonization of target cells, thereby making them more susceptible to phagocytosis.

3. Antibody Dependent Cell Mediated Cytolysis
ADCC requires antibody, but the cytolysis does not require complement activity. The effector cells are neither T nor B cells but are called K (Killer) cells. The specificity of this reaction resides in the antibody molecule. Only very small amounts of antibody are required; so this mechanism is effective in areas where antibody concentration may be minimal, e.g. at the site of tumors.

4. Macrophages
Phagocytosis is the nonspecific mechanism by which body tries to eliminate invading organisms. Foreign materials are ingested by the macrophages and later digested intracellularly. The myeloperoxidase present inside the phagocytes destroys the bacteria (Chapter 20). When a foreign particle enters the body, the macrophages phagocytose it, and present the antigens to the lymphocytes.
STRUCTURE OF IMMUNOGLOBULINS

Immunoglobulin is abbreviated as Ig. The terms gamma globulin and immunoglobulin are not synonymous. Gamma globulin is the term describing its mobility in electrical field. Most of the immunoglobulins have the gamma mobility; but some may move along with beta or even with alpha globulins. Immunoglobulin is a functional term, while gamma globulin is a physical term. The antibody reacts with antigen very specifically. This property is widely used in purification of proteins and for affinity chromatography. This affinity is based on the complementary nature of the three dimensional structure of antigen and antibody. If there is a protuberance in the antigen, there is a corresponding cleft in the antibody structure.

In 1962, Rodney Porter and Gerald Edelman independently proposed the structure for immunoglobulin molecule, for which both of them were awarded Nobel prize in 1972.

Heavy and Light Chains

The structure of IgG molecule is shown in Fig. 49.1. It is made up of 2 heavy (H) chains and 2 light (L) chains, combined through disulfide bridges. In the case of IgG, H chains are composed of 440 amino acids and L chains made up of 214 amino acids. Depending on the heavy chain make up, the immunoglobulins are differentiated into 5 major classes.

1. Immunoglobulin-G (IgG) is made up of heavy chain γ (gamma)
2. IgM has μ (mu) heavy chain
3. IgA has α (alpha) heavy chain
4. IgD contains δ (delta)
5. IgE heavy chain is called ε (epsilon).

The light chains are either κ (kappa) or λ (lambda) in all the classes. For example, IgG may consist of either γ2 κ2 or γ2 λ2. In human beings, 60% light chains are of κ variety and 40% are of λ type.

Variable and Constant Regions

Both the heavy and light chains contain relatively variable (V) and constant (C) regions with regard to their amino acid composition. VL and CL are the general terms for these regions on the light chain; while VH and CH specify variable and constant regions on the heavy chain (Fig. 49.1). The first 108 amino acids in light chains and first 118 amino acids in γ heavy chains constitute the variable
Fab and Fc Portions

i. Papain (proteolytic enzyme from papaya) cleaves the Ig (Fig. 49.2), so that two Fab (fraction antibody) portions and one Fc (fraction crystallizable) portion are produced. The antigen binding part of the antibody is in the Fab fragment.

ii. The cleavage takes place in the hinge region, where Ig molecule can have mobility in 3 dimensional space, so as to adjust for tight grip on the antigen. Carbohydrate groups of the Ig molecule are also situated in the hinge region. The area capable of complement binding lies in the Fc portion.

iii. Another proteolytic enzyme, pepsin, cleaves Ig at another site (Fig. 49.2) so as to yield F(ab)2, where two Fab portions are combined together.

Different Classes of Immunoglobulins

1. Immunoglobulin G (IgG)

a. IgG contains two heavy chains and two light chains; heavy chains being of gamma type (Figs 49.1 and 49.3 and Table 49.1). Due to its sedimentation coefficient, it is sometimes referred to as 7S Ig.

b. IgG is the major antibody; it constitutes about 75-80% of total immunoglobulins in circulation.

c. It is the antibody seen in secondary immunologic response.

d. It can pass from vascular compartment to interstitial space. It can cross-placental barrier, and protects the newborn child from infections. These maternal antibodies are seen in neonatal circulation up to 2-4 months.

e. Placental crossing of IgG also explains the Rh iso-immunization. This occurs when mother is Rh-negative, and fetus is Rh-positive, and when ABO system antigens are similar to both mother and fetus. During parturition, fetal RBCs may enter into maternal circulation, leading to formation of anti-Rh antibodies. During next pregnancy, these antibodies, being IgG in class, can enter into fetal circulation, causing fetal hemolysis, neonatal jaundice, and in severe cases, neonatal death or miscarriage. Passively injected anti-Rh antibody, when injected within 24 hrs of delivery of first child, will avert the iso-immunization and can protect future pregnancy.
In cows, placental crossing of immunoglobulin does not occur, but the colostrum (first day's milk) contains good quantities of antibody which can cross the intestinal walls of newborn calves. Human colostrum contains immunoglobulins to a lesser extent.

IgG can bind with microbes, and the Fc portion can fix with macrophage, so that phagocytosis is made easier. This is called opsonization effect of antibody. Antibodies coating the target cells will sensitize them for killing by lymphocytes by antibody dependent cell mediated cytolysis (ADCC). Only IgG class is active for ADCC mechanism.

2. Immunoglobulin M (IgM)
   a. IgM are macroglobulins or 19S immunoglobulins.
   b. Five subunits, each having 4 peptide chains (total 10 heavy chains and 10 light chains) are joined together by a J-chain polypeptide (Fig. 49.3). It can combine with 5 antigens simultaneously, and so IgM is very effective for agglutinating bacteria.
   c. Being a large molecule, it cannot come out of vascular space.
   d. IgM are the predominant class of antibodies in primary response.
   e. Natural antibodies are IgM in nature. Thus, a person having blood group A antigen will have anti-B antibodies in his circulation (iso-hemagglutinins). These are produced without any known antigenic stimulation, and hence called natural antibodies. These IgM antibodies cannot cross placenta, and therefore the fetus, even though it carries an incompatible antigen, is protected from natural antibodies of the mother.

3. Immunoglobulin A (IgA)
   a. IgA usually are dimers (total 4 heavy chains and 4 light chains). The J chain connects the dimers (Fig. 49.3).
   b. They are the secretory antibodies seen in seromucous secretions of gastrointestinal tract, nasopharyngeal tract, urogenital tract, tears, saliva, sweat, etc.
   c. The dimers are stabilized against proteolytic enzymes by the secretory piece. The secretory piece is produced in liver, reaches to the intestinal mucosal cells, where it combines with IgA dimer to form the secretory IgA which is then released.

4. Immunoglobulin E (IgE)
   a. They are cytophilic antibodies. They mediate allergy (Greek, allo = other; ergon = work), hypersensitivity and anaphylaxis.
   b. They have the property to fix on mast cells and basophils. When certain antigens such as penicillin are injected a few times, IgE class antibodies are produced which anchor on mast cells. When the same chemical is injected next time, the antigens fix on such antibodies, causing mast cell degranulation, and release of histamine and slow reacting substance.
   c. This leads to vasodilatation, hypotension and bronchiolar constriction. This is the basis of penicillin anaphylaxis, hay fever caused by fungus, asthma by pollen and urticaria by absorbed food elements. The peak of this reaction will be at about 30 minutes; hence called immediate type hypersensitivity.
   d. IgE level in serum is markedly increased in helminthic infections.

Isotypes, Allotypes and Ideotypes
Isotypes are variants in molecules seen in all normal persons, e.g. classes and subclasses of immunoglobulins (G, M, A, etc.). Allotypes are a variation within a subclass, and depend upon allelic forms. Thus only one form will be seen in one person, e.g. the Gm groups of IgG molecules. If a person is
Gma +ve, each of his IgG1 molecules has a sequence Asp-Glu-Leu-Thr. Another person with Gma –ve will have this sequence changed to Met-Glu-Glu-Thr. About 30 genetic markers of Gm groups on γ heavy chain are discovered. Idiotypic variation is individually specific to each immunoglobulin molecule. The idiotypic determinants are located in the variable part of antibody, i.e. the antigen recognition site. In 1984, Nobel prize was awarded to Niels Jerne for his work on idiotypes as well as for theories on antibody production.

PARAPROTEINEMIAS

1. Multiple Myeloma (Plasmacytoma)
   A. When Ig-secreting cells are transformed into malignant cells, one clone alone is enormously proliferated. Thus, Ig molecules of the very same type are produced in large quantities. This is seen on electrophoresis as the myeloma band or monoclonal band or M band with a sharp narrow spike (see Fig. 28.2).
   B. Multiple myeloma is characterized by paraproteinemina, anemia, lytic bone lesions and proteinuria. Bone marrow examination reveals large number of malignant plasma cells. Spontaneous pathological fracture of weight bearing bones, rib and vertebrae may occur. X-ray shows punched-out osteolytic lesions.
   C. Hypercalcemia and hypercalciuria are therefore common features. Raised beta-2-microglobulin (Mol. wt. 11,800 D) is another feature of multiple myeloma.
   D. Total Ig content may be very high; but useful antibodies may be very low, so that general immunity is depressed and recurrent infections are common.
   E. The prognosis is generally good, and average survival is more than 5 years with adequate chemotherapy and local irradiation.

   Monoclonal gammapathies are characterized by the presence of a monoclonal protein which can be detected by serum protein electrophoresis and typed by immunofixation electrophoresis. The light chains are produced in excess which is excreted in urine as Bence Jones proteins (BJP) when their serum level increases. Detection of BJP in urine and assay of free light chains in serum are of diagnostic and prognostic significance in multiple myeloma. It is seen that excretion and deposition of monoclonal light chains in kidney results in impairment of renal function.

2. Bence-Jones Proteinuria
   A. Henry Bence-Jones described it in 1848. This disorder is seen in 20% of patients with multiple myeloma. Monoclonal light chains are excreted in urine. This is due to asynchronous production of H and L chains or due to deletion of portions of L chains, so that they can not combine with H chains.
   B. The Bence-Jones proteins have the special property of precipitation when heated between 45 and 60°C; but redissolving at higher than 80°C and lower than 45°C. These proteins may block kidney tubules, leading to renal failure. So, myeloma with Bence-Jones proteinuria has poor prognosis.
   C. Bradshaw’s test is also positive, when a few ml of urine is layered over a few ml of concentrated hydrochloric acid, a white ring of precipitate is formed.

3. Heavy Chain Disease
   Some portions of H chains are deleted during synthesis, so that they cannot join with L chains to form normal Ig. These defective heavy chains are excreted through urine. Gamma chain disease is associated with hepatosplenomegaly and lymphadenopathy. Alpha chain disease is associated with abdominal lymphoma and malabsorption.

4. Waldenstrom’s Macroglobulinemia
   In this condition, IgM level in blood is increased considerably with a monoclonal peak. This is due to malignant proliferation of IgM clones. Males are affected mostly. Since IgM are macromolecules, they may form aggregates or cryoprecipitates, serum viscosity is increased. This is the basis of Sia test. A drop of serum is allowed to fall into a tube containing water. Normal serum will spread. Hyperviscous serum will form globular precipitate. Hyperviscosity leads to recurrent bleeding.

5. Amyloidosis
   About 20% patients with myeloma develop Amyloidosis. Amyloid deposits are seen in liver and kidney. Congo Red will stain amyloid deposits. In the case of myeloma, the amyloid fibrils contain polymerized variable region of light chains of Ig and termed AL. Amyloidosis may also be seen secondary to chronic inflammatory conditions, where the deposited proteins are Amyloid-A (AA) with a molecular weight of 8,000. This is derived from another serum precursor termed S-AA, an acute phase protein of 90 kDa. Beta-2-microglobulin and transthyretin are other precursor proteins of amyloid deposits. S-AA and S-APP are further described in Chapter 48.

6. Hypergamma globulinemia
   A. Chronic infections, where antibody production is high. Examples are leprosy, tuberculosis, syphilis, malaria, kala-azar, subacute bacterial endocarditis
   B. Aberrant immune reactions such as rheumatoid arthritis, collagen disorders, glomerulonephritis, and such auto-immune disorders where cryoglobulins may also be present.
   C. Paraproteinemias such as in multiple myeloma and Waldenstrom’s macroglobulinemia.
7. Hypogamma globulinemia
Decrease or absence of immunoglobulin levels may be seen in congenital or acquired conditions. Deficiency can also occur due to loss of proteins as in nephrotic syndrome. A primary failure in production may occur as a congenital X-linked disorder (Bruton’s disease). Decreased production may also be secondary to diseases like myeloma, leukemia or drug induced.

COMPLEMENT SYSTEM
Complement factors are proteins present in serum. The cell lysis by antibody is mediated by complement system. Complement is generally abbreviated as C'. There are 9 components, designated as C1 to C9.

The complement activity is abolished if serum is incubated at 56°C for 30 minutes, as most of the components are thermodabile. The half-life of complement system at room temperature is only a few hours. The characteristics of complement components are shown in Table 49.3.

Complement Activation
When Ig is bound on the bacteria, the Ig fixes the first component of complement, C1. It has 3 subunits; C1q, C1r and C1s which are stabilized by Ca++. C1q binds with the antibody. It has 18 polypeptide chains, branching into 6 flower like blooms connected to one stem. These branches can fix to antibody subunit chains. Then C1r and C1s are bound. C1s (C-1-esterase) when thus activated, acquires proteolytic activity. It in turn, cleaves and activates the next component, C4. Thus a multi-enzyme cascade system is activated, leading to chemical amplification of the original message. The waterfall like pathway of activation of complement system is given in Figure 49.4. The final components when activated, create microscopic holes in the target cell membrane. Osmotic entry of water through these pores will cause lysis of the target cell.

Fig. 49.4. Pathways of complement activation

The breakdown products, C3a and C5a activate phagocytosis, chemotaxis and immune adherence while increasing the capillary permeability.

Alternate Pathway
Apart from this classical pathway, microbial polysaccharides can activate the properdin system, so as to bypass the initial complement components. This system includes properdin, Factor D, Factor B, Factor I, and Factor H. Since this does not require specific antibodies, the alternate pathway acts as the first line of defense against invading microorganisms.

C1-esterase-inhibitor is an alpha-2 globulin with molecular weight of 105,000. It can inhibit not only C1-esterase (C1s) but many other plasma enzymes such as plasmin, kallikrein, Hageman factor, etc. Hereditary angio-neurotic edema is an inherited autosomal dominant disease, in which C1-esterase inhibitor is absent. This leads to uncontrolled activation of early components of complement system, with generation of kinin-like substances. Death may occur due to laryngeal edema.

Diagnosis is by showing normal C1 but diminished C4 and C1-esterase inhibitor.
IMMUNODEFICIENCY STATES

1. Combined Immunodeficiency

There is defect in maturation of stem cells. Both cellular and humoral immunity are defective. Relatively benign types are Wiskott-Aldrich syndrome (sex-linked) and ataxia telangiectasia (autosomal recessive). In both, lymphoreticular malignancies are common.

2. Humoral Immune Deficiency

This may be a selective primary deficiency affecting only one of the G, M or A classes of immunoglobulins. In IgG deficiency, the affected persons suffer from repeated pyogenic infections. IgA deficiency lowers the resistance to gut commensals leading to malabsorption syndrome. Incidences of autoimmune diseases such as hemolytic anemia are high in primary agammaglobulinemia.

3. Cellular Immune Deficiency

Primary deficiency of T cell leads to severe viral and monilial infections. Thymus may be absent (Nezelof's syndrome), aplastic (DiGeorge syndrome), or normal.

4. Defect of Phagocytosis

Chronic granulomatous disease is a sex-linked inherited disease, where peroxidase is deficient inside the phagocytes. Macrophages can engulf bacteria, but cannot digest them; and bacteria may multiply inside the macrophages. Recurrent granulomas due to catalase positive and peroxidase negative organisms (Staphylococcus aureus) are common. In myeloperoxidase deficiency, infections by peroxidase positive bacteria such as hemophilus are common. In Chediak-Higashi syndrome, the neutrophils show defective degranulation and sluggish motility with consequent pyogenic infections.

5. Secondary Immunodeficiency

Secondary defects in lymphocyte function are seen in many clinical conditions such as malnutrition, leukemias and lymphomas. In multiple myeloma, though total immunoglobulins are increased, the biologically active ones are depressed. The acquired immunodeficiency syndrome (AIDS) is described in detail in Chapter 50.

Primary and Secondary Immunoresponses

When an antigen is injected, antibodies in blood appear within about 10 days, reach a peak level within 20 days and response declines by about 30 days. The IgM molecules will be predominant in this primary response.

When the same antigen is reinjected into the same animal after a few months, the antibody response is quicker (within 3 days), stronger (100 to 1000 times more quantity of antibody), more avid (IgG type) and more prolonged (response lasts for months). This is the secondary immunoresponse, which is due to the memory cells produced in the primary response (Fig. 49.5). This is the basis of immunization.

Active immunity is induced by immunization with toxoid, or killed or attenuated organisms. Examples are diphtheria, pertussis, tetanus (DPT) vaccine, oral poliovaccine and hepatitis B vaccine.

In passive immunity, protection is given by preformed antibodies. This is used in immunotherapy against diphtheria, tetanus, snake-bites, etc.

Transposition of Genes

Body can easily produce $10^{10}$ diverse antibodies against different antigenic stimulation. Such huge numbers of genes are not available in the Ig loci. It is possible to explain the mechanism as transposition of genes or gene rearrange-
ment or somatic recombination of DNA. In humans, the gene for kappa light chain is in chromosome No. 2, that for lambda chain is in chromosome No. 22 and those for heavy chains are in chromosome No. 14. Each L chain gene contains over 500 VL (variable light) segments, 5–6 JL (joining light) segments and 10–20 CL (constant light) segments. During differentiation of B lymphocytes, one out of 500 VL segment is brought from a distant site on the same chromosome to the genes of JL and CL segments. This recombination system is similar to the spliceosomes described (See Figure 41.11). In Figure 49.6, it is depicted that 200th VL, 4th JL and 9th CL segments of germline are brought together by cutting and splicing at specific points of DNA. In this given example, random rearrangement allows VL (200)-JL(4)-CL(9) segments to remain in the gene, while other regions of genes are deleted. These VL-JL-CL segments are transcribed as a single mRNA, and later translated into a specific immunoglobulin light chain. Another permutation is taking place in another cell. Thus millions of cells together can produce endlessly diverse light chains.

Gene, Cistron, Split gene, Polypeptide
In classical genetics, it is stated that one gene determines one character, which is the result of combined action of many proteins. In classical biochemistry, a cistron is the basic unit which encodes one polypeptide chain. But this concept is also changed. As shown previously, many such cistrons could be spliced and rearranged. In other words, many genes together can produce one peptide chain, by means of transposition. Susumu Tonegawa did pioneering work in somatic recombination (gene shuffling) in relation to antibodies, who was awarded Nobel prize in 1987.

Molecular Structure of Antigens
Blood groups of RBCs express more than 160 antigens. The most important of them is called ABO system. The RBC of the person may carry antigen A, B or AB; if none of these antigens are present, it belongs to blood group O. Group A person's serum contains anti-B antibody. Therefore when RBCs of B group are introduced into the person having blood group A, there will be agglutination of the introduced cells. This is the basis of blood transfusion.

The ABO system antigens are glycoproteins present on surface of all cell membranes. The membrane surface will carry a protein into which oligosaccharide unit is attached. The H locus codes for fucosyl transferase, which adds fucose to a terminal galactose unit through alpha-1,2 linkage. This is the precursor for both A and B antigens. Since “h” allele of H locus codes for an inactive fucosyl transferase, a person having “hh” combination will not produce the precursor; neither A nor B substances are added; hence the person’s blood group becomes O.

Those individuals having Hh or HH allele combinations can produce precursor molecules. Such persons having BB or BO alleles will generate a specific transferase which adds a galactose unit to the fucose with alpha-1,3 glycosidic linkage. Persons having AA or AO alleles can generate another transferase, which adds N-acetyl galactosamine to the fucose

Fig. 49.6. Production of diversity in immunoglobulins
through alpha-1,3 glycosidic linkage. Thus the molecular difference between A group and B group is only with regard to the N-acetyl unit. The immunological system can differentiate even this minor alteration.

If the person is belonging to AB group both transferases are active and both antigens are produced. In persons lacking in A and B alleles, the transferases are absent; the oligosaccharide is ending with fucose unit and his blood group will be designated as O (Chapter 10).

**T Cell Receptors**

The B cells have immunoglobulins on their cell surface, which are involved in the antigen recognition by B cells. However, the T cell receptors are more complex (Fig. 49.7). The receptor molecule is made of two polypeptide chains, alpha and beta, each with two immunoglobulin-like domains. The two chains are held together by one interchain disulfide bridge. Each chain has a transmembrane hydrophobic part, which anchors the polypeptide into the T cell membrane. Both chains are glycosylated.

**HLA Antigens**

The T cell recognition is also closely related to the HLA (human leukocyte antigen) system. When organs are transplanted, the donor and receiver are matched for HLA system. Joseph Murray did the first kidney transplantation in 1954 and Edward Thomas did the first bone marrow transplantation in 1956; both of them received Nobel prize in 1990. But Christian Bernard, who did the first heart transplantation in 1964, was omitted from the Nobel prize list. The genes of major histocompatibility complex (MHC) are involved in the recognition between self and non-self antigens. In human beings, the MHC genes are present on chromosome 6. There are A, C, B, D and DR loci. All these loci together contain more than 150 alleles. Permutation and combination of them could produce an astronomical number of variations. Hence the antigenic constitution of one person will be entirely different from another one. These are main transplantation antigens, responsible for rejection of allograft. Frank Macfarlane Burnet and Peter Brian Medawar were awarded Nobel prize in 1960 for elucidation of basic rules in transplantation immunity and acquired immunological tolerance.

**Soluble Factors**

Soluble factors released by cells are known as cytokines in general. Factors produced by leukocytes are termed as interleukins; those by myeloid cells are monokines and those produced by lymphocytes are called lymphokines. The lymphokines include the following:

1. **Interleukins (IL)**
   - They are a group of cytokines (signaling molecules) that were first seen to be expressed by white blood cells (leukocytes). The function of the immune system depends in a large part on interleukins, and rare deficiencies of a number of them have been described, all featuring autoimmune diseases or immune deficiency. The majority of interleukins are synthesized by helper CD4+ T lymphocytes, as well as through monocytes, macrophages, and endothelial cells. They promote the development and differentiation of T, B, and hematopoietic cells. Interleukins are polypeptide growth factors secreted by leukocytes. About 20 interleukins are isolated.
   - **IL-1** stimulates production of receptors for IL-2 on lymphocytes.
   - **IL-2** stimulates T cells and NK cells and differentiates them into effector cells capable of killing cancer cells. IL-2 is therefore useful to produce lymphokine-activated killer (LAK) cells. Lymphocytes cultured with cancer antigens and stimulated by IL-2 can act as specific (LAK) cells. Experimentally, these LAK cells are being used as a form of immunotherapy in cancer patients with limited success.

2. **Interferons (IFN)**
   - They inhibit viral multiplication in host cells, modulate cell differentiation and inhibit oncogene expression. Please also see Chapter 48.

3. **Macrophage migration inhibition factor**
   - The MIF helps the accumulation of macrophages at the site of reaction. The resulting erythema and induration form the basis of skin tests. Details of such cytokines are given in Table 49.4.

**Related topics**

Hybridoma technique to produce monoclonal antibody is described in Chapter 55. GCSF, GMCSF, ICAM, Interferons, MCSF, MIP, MCP, PDGF, Selectin, TGF, VCAM and VEGF are described in Chapter 48.
The reader will be able to answer questions on the following topics:
1. Acquired immunodeficiency syndrome (AIDS)
2. Human immunodeficiency virus (HIV)
3. Immunology of AIDS
4. Laboratory analysis of AIDS

**Epidemic of AIDS**
Towards the end of the 20th century, medical science was able to control and even conquer many of the previously incurable diseases. But AIDS has now become a disease of pandemic proportions. By the end of 2009, about 60 million HIV seropositive individuals were living in the world, which included 3.5 million children. Every minute, around 12 people become newly infected with HIV.

In 1981, a cluster of 5 cases of *Pneumocystis carinii* pneumonia were reported in USA. These protozoa can produce pneumonia only in immunodeficient individuals. Based on the clinical manifestations, the disease was named as **Acquired Immunodeficiency Syndrome** with acronym of AIDS. In 1983, Francoise Barre-Sinoussi (Nobel prize, 2008) showed that the disease is due to a retrovirus (virus having reverse transcriptase enzyme). The isolation of a virus from the lymphocytes of the AIDS patients was done in 1984 independently by Robert Gallo at the National Institute of Health, USA and Luc Montagnier at the Pasteur Institute, Paris. The latter was awarded Nobel prize in 2008. The virus was originally designated as HTLV-III (human T cell leukemia virus). In 1986, it was redesignated as HIV (Human Immunodeficiency Virus). By retrospective analysis, it was inferred that the human pandemic started in Africa by around 1970, and that a simian virus transformed into HIV by around 1700.

**Transmission**
1. 80% of the total patients got the infection as a sexually transmitted disease.
2. In about 15% of patients, the disease was transmitted through blood. The drug abusers usually use the same needle without any sterilization for intravenous injection. The risk of getting HIV is high in patients who receive blood transfusion many times, e.g. hemophilia patients.
3. In the rest 5% cases, virus may be transmitted from mother to fetus through placenta. About 30% of infants born to HIV positive mothers may get the infection.

**Biochemistry of AIDS and HIV**

**The Indian Scene**
The virus entered in India in 1980. From 1986 onwards, the Indian Council of Medical Research has started the serosurveillance against HIV. The first seropositive individuals in India were identified in 1986. The Government of India has established the National AIDS Control Organization (NACO) in July 1992 for the prevention of AIDS. The virus has already entered into 1 per 100 persons in India (1%). In certain areas of this country, the seropositivity is 30% in high-risk groups (sex workers, intravenous drug users). India has the second largest number of HIV infected people; the estimate is about 8 million persons.

**Fig. 50.1.** Course of HIV infection; I = window period; II = seropositive period; III = AIDS disease. Black line is antigen in blood; Red dots indicate antibody response.
Natural Course of the Disease

1. Window Period
When the virus enters the body, it is multiplied in the body cells, but it cannot be detected easily. This is called the window period (Fig. 50.1). The viral capsid antigen p24 can be detected in the blood during this time.

2. Seropositive Stage
After a few months, antibodies are seen in circulation. This is called seropositivity (Fig. 50.1). During this period, the person is completely normal. However, this person is a carrier of the disease, and can transmit the disease to others. About 10% seropositive individuals will go for the 3rd stage of AIDS disease within 5 years, about 50% will get AIDS within 10 years and about 90% enter into the disease state within 15 years. For each AIDS patient, there are 100 seropositive persons in the general population.

3. AIDS Disease
The third stage is when the clinical manifestations start. By this time, the immune status of the individual is depressed. Therefore, commensal microbes will start multiplication inside the body. Patient usually succumbs to death within about 2 years after entering this stage.

4. Clinical Presentations
Lymphadenopathy and fever may be seen by the end of the second stage. The AIDS related symptoms (ARS) are wide. Since the immunity is deficient, nonpathogenic microorganisms enter into the body and produce lesions in skin, gastrointestinal tract, lungs, urinary tract and brain. Gastroenteritis and tuberculosis are the predominant pattern in India. In all the cases, there will be weight reduction.

5. Laboratory Analysis
i. The antibodies in the blood are detected by the ELISA test (Chapter 54). ELISA positive blood is then confirmed with Western blot analysis (Chapter 55). In ELISA, antibody against only one antigen (gp 120) is being tested; so there is probability of false results.
ii. In Western blot analysis, antibodies against 6 different components of the virus are analysed; so it is confirmatory.
iii. T-helper count is lowered. The normal level is more than 400/cmm. In AIDS patients, the level is always below 300. As the disease progresses, the helper cell count is correspondingly lowered.
iv. In the last stages, the antigen, especially, p24 starts to rise.
v. By Real time PCR (RTPCR) (Chapter 55), the number of HIV particles in blood can be estimated. A value of less than 5000 copies per ml of blood has good prognosis, while a count more than 1 lakh per ml means very bad prognosis.

THE HUMAN IMMUNODEFICIENCY VIRUS

1. Structure
i. HIV belongs to the retrovirus group. They are RNA-containing viruses that replicate with the help of the reverse transcriptase (RT) or RNA dependent DNA polymerase. A schematic representation of the structure of the virus is shown in Figure 50.2.
ii. The virus has a cylindrical core, containing two copies of single stranded genomic RNA.
iii. The protein components are named after its molecular weight. For example, protein having molecular weight 32,000 Daltons is called p32.
iv. The core of the virus contains reverse transcriptase (p66 and p55), an endonuclease (p32), nucleocapsid protein (p9) and a
protease (p10). The viral core is surrounded by the major capsid antigen (p24). The outer shell is composed of a myristylated protein, the membrane antigen (p17).

2. Virus Entry
   i. The binding of HIV with target cell is through a receptor mechanism. The gp 120 of the virus envelope will specifically bind with CD4 molecule on the surface of target cells. Thus CD4 acts as a receptor for the virus.
   ii. The CD4 molecules are present on the surface of T-helper cells and therefore helper cells receive the maximum attack of HIV.
   iii. Macrophages, monocytes, Langerhans' cells, folliclar dendritic cells and glial cells are also susceptible to HIV entry and propagation. Macrophages act as the reservoir of the virus.

Replication of HIV
The virus has an extraordinary rate of replication; over 10 billion particles are produced per day inside the host. After entry, the viral RNA is acted upon by the reverse transcriptase (RT). Based on the RNA, a DNA strand with complementary sequence (minus strand) is produced. Then RNA strand is hydrolysed by RNase-H. Keeping the DNA minus strand as the template, a complementary (plus strand) of DNA is synthesised. This DNA double strand (proviral DNA) migrates into the nucleus of the host cell. The viral DNA is then integrated into the host cell DNA by the action of the viral integrase (p32).

Retroviruses do not replicate in non-dividing cells. Similarly HIV also requires activation and division of T cells for the viral particle synthesis. The viral genes are transcribed and translated by the host cell mechanisms.

Assembly and Maturation of HIV
The products of gag and pol genes, proteins p55 and p160, the precursor big proteins are incorporated into the virus assembly. The cleavage pattern and mature forms are shown in Figure 50.3. This is then cleaved by host cell proteases into gp120 and gp41. These are then inserted into host cell membrane. Then the virions are evaginated out. During this process, part of the host membrane, along with gp120 and gp41 are added. The infected host cell lives only for a day and half.

HIV genes
There are 3 structural genes (gag, pol and env), 3 regulatory genes (tat, rev and nef) and 5 accessory genes (vif, vpr, vpu, vpt and tev/tnv) in between long terminal repeats (LTR) (Fig. 50.3). The LTR contains transcriptional control elements. LTR is also useful for the integration of provirus into cellular genes. An interesting finding is that gag and pol genes overlap by 241 nucleotides (Fig. 50.3). The transcription start signal as well as some direct control elements are in the LTR region. The positions of the other 3 regulatory genes (tat, rev and nef) are shown in Figure 50.3. The enhancer element is between –79 to –120 nucleotides. One factor, NFkB, released from the activated T cell, binds in this region, and then transcription is enhanced. In the resting T-cell, this factor is not available.

   The negative regulatory element (NRE) is at –157 to –410 nucleotides. This generally inhibits the transcription. But a protein induced in activated T cells, designated as nuclear factor of activated T cells (NFAT-1) binds in this region, and the inhibition is removed.

Immunology of AIDS
   i. The CD4 (T-helper) lymphocytes are decreased in number, leading to immunodeficiency. The gp120 surface unit could specifically attach with CD4 molecule present on the surface of T-helper cells. Therefore HIV preferentially enters into the T-helper cells and they are lysed.
   ii. Macrophages and monocytes act as the reservoir of HIV infection, which disseminate the virus to various organs, including CNS. In turn, macrophage activity is also reduced.
   iii. Since T-helper cells play a pivotal role in the immunological system, their deficiency will lead to suppression of almost all the immunological effectors.
   iv. T-helper (CD4) count is less than 400/cu.mm. of blood. T-killer cytotoxic activity is reduced.
v. Antibody response against a foreign antigen is poor. Lymphokines such as interferon, interleukin-2, etc. are lowered.

vi. When all the effector mechanisms of immunity are thus paralysed, opportunistic pathogens get entry into the body.

**Immunoselection of virus**

In the early phase, the HIV enters macrophages through a receptor jointly made by CD4 and CCR5 proteins on the surface of macrophages. The HIV surface antigen (gp 120) has a perfect fit only for this type of receptors on the macrophage (M-tropic HIV). So in the early period, lymphocytes are spared. After a few years, gp120 is mutated, so that dual tropic viruses are produced. In the late phases of the diseases, T-tropic HIV are generated. By this time, all the gp-120 molecules are mutated, such that they can fit only with T lymphocyte receptors made up of CD4 and CXCR4 proteins. So T helper lymphocytes are preferentially killed leading to disease manifestations.

**Genetic Resistance**

About 1% of population are resistant to HIV infection. CCR5 and CD4 proteins together form the receptor for HIV. Thus normal CCR5 gene allows the entry of HIV into macrophages. In contrast, in people having mutated CCR5 gene, the protein is not displayed on the macrophage surface. Without the CCR5 protein to latch onto, HIV fails to invade macrophages. Thus an individual with mutated CCR5 gene escapes the HIV infection.

**Genetic Heterogeneity of Virus**

Two types, HIV-1 and HIV-2 are recognised; HIV-1 is predominant. There are many subtypes of HIV-1. Different subtypes may be seen in the same patient. Moreover each type exhibits remarkable microheterogeneity. There is high mutation rate in the virus. Such mutations accumulate to produce the various types, strains and microvariations. About 15% of amino acids in the envelope gp120 are highly variable. Therefore, the antigenicity of the virus also varies, and virus can escape from the immune attack.

**Prospects of a Vaccine**

This hypervariability in the gp120 also makes it difficult to produce an effective vaccine. Trials are running with recombinant gp120 and gp160 vaccines. About 15 candidate vaccines are in the different stages of testing. But it may take few more years to perfect an efficient vaccine.

**ANTI-HIV DRUGS**

i. Reverse Transcriptase (RT) inhibitors; nucleoside analogues: Dideoxy nucleosides are nucleosides, where oxygen is absent from both 2' and 3' positions of the ribose group. The DNA chain is produced by 3',5'-phosphodiester linkages. In the dideoxy nucleoside, there is no hydroxyl group in the 3' position and hence chain is terminated. So, they inhibit RT of the HIV. The drugs licensed for clinical use are AZT (dideoxy thymidine, azidothymidine, Zidovudine); ddI (dideoxy inosine, didanosine, Zidasine); ddC (dideoxy cytidine, Zalcitabine); d4T (Stavudine), 3TC (Lamivudine) and Abacavir.

ii. RT inhibitors; non-nucleoside analogues: These agents bind to regions outside the active site of the HIV-RT, and make the enzyme inactive. Examples are Delavirdine, Nevirapine, Loviride and Efavirenz.

iii. RT inhibitors; nucleotide analogue: One example is Adefovir.

iv. Protease inhibitors: They are extremely selective for HIV protease. So, they block final assembly and package of HIV particles. Examples include Saquinavir, Ritonavir, Indinavir and Nelfinavir.

v. A combination of drugs (HAART, highly active anti-retroviral therapy) will reduce the virus load and prolong the life of the patient. At present, there is no absolute cure for HIV.

**Prevention**

Since there is no cure for AIDS, and vaccines are still decades away, public education and awareness are the only means to limit the spread of HIV infection. Since the major method of transmission is through sexual contact, avoidance of extramarital relationships will stop the spread. All the blood samples should be tested for the presence of HIV antibodies before transfusion. Syringes and needles should be properly sterilized. Disposable syringes and needles are to be used and destroyed immediately after use. Boiling for 10 minutes will inactivate the virus. Ordinary autoclaving at 120°C for 20 min is effective to sterilize instruments and gloves. Blood spills can be decontaminated by washing with 1% sodium hypochlorite solution, containing 10,000 ppm chlorine. Heat sensitive instruments may be decontaminated by immersing in 2% glutaraldehyde (cidex) for 3 hours.
The term “cancer” is derived from Latin word “cancrum” or Greek “karkinoma”, that is equivalent to Sanskrit term “karkitakam”, which means “crab”. The disease is so called because of swollen veins around the area, resemble a crab’s limbs. Indian Medical Science had identified cancer, gave the name “arbuda”, which literally means the number $10^8$, identifying the extreme cellularity of the cancer tissue. The International Union Against Cancer (UICC; Union Internationale Contre le Cancer) has defined cancer as a disturbance of growth characterised by excessive proliferation of cells without apparent relation to the physiological demands of the organs involved. Oncology deals with the etiology, diagnosis, treatment, prevention and research aspects of cancer.

**Etiology of Cancer**

All cancers are multifactorial in origin. They include genetic, hormonal, metabolic, physical, chemical and environmental factors. Most human cancers are spontaneous.

All cancers originate usually from one aberrant cell, which goes on to multiply and produce a tumor mass. One mutation occurs out of $10^6$ cell divisions. By the time a person reaches adulthood, about $10^{26}$ cell divisions have occurred. Thanks to the surveillance by the immune system, these aberrant cells are usually destroyed. As age advances, the number of mutations accumulate, hence the statistical probability of the incidence of cancer is increased. No wonder, cancer is a disease of old age, especially after 60 years.

Cancer is the second most common cause for death in developed countries, second only to cardiovascular diseases. When the average life expectancy is less, as in the case of India, the death due to cancer is also low. Table 51.1 shows the incidence of cancer in different organs. The figures are compiled from WHO and ICMR publications. Oral cavity and upper gastrointestinal tract are the organs where cancer occurs most often in India. On the other hand, lungs and colon are the common sites for cancer in Western countries.

**Mutagens**

Any substance which increases the rate of mutation can also enhance the rate of incidence of cancer. Therefore all carcinogens are mutagens. Examples are X-ray, gamma-ray, ultraviolet ray. Some human cancers are caused by chemicals. These may be introduced into the body by means of (a) occupation (aniline, asbestos), (b) diet (aflatoxins) or (c) lifestyle (smoking). Chemical carcinogens act cumulatively. Tobacco, food additives, coloring agents, and aflatoxins are common carcinogens in our environment.

Thousands of chemicals are known mutagens and carcinogens. A selected small list of chemical carcinogens is given in Table 51.2 and Figure 51.1. Methyl cholangrene is a powerful carcinogen, only nanograms are sufficient to produce a tumor in a mouse (Figs 51.1 and 51.2).

**Aflatoxins**

They are a group of chemically related compounds synthesised by the fungi, *Aspergillus flavus*. The mould grows on rice, wheat and groundnut, when kept in damp conditions. The fungi may grow in cattle fodder, which may enter into human body through the cow’s milk. Aflatoxins are powerful carcinogens, which produce hepatomas (Fig. 51.1).

**Cigarette**

Lung cancer is associated with the habit of cigarette smoking. Cigarette contains many carcinogens, the most important group being benzo(a)pyrenes. Other important deleterious substances in cigarette smoke are nicotine, carbon monoxide, nitrogen dioxide and carbon soot. Statistically, it is estimated that one cigarette reduces 10 minutes from the life span of the individual. The incidence of lung cancer is increased to 15 times more in persons smoking 10 cigarettes per day and 40 times more when smoking 20 cigarettes per day. Thus WHO suggested the slogan 'cigarette smoke is injurious to health'. Moreover, non-smoking spouse of a heavy smoker will have 5 times more probability to get lung cancer than a non-smoker. This effect of *passive smoking* made the International Union against Cancer (UICC) to change the slogan to 'Your smoking is injurious to our health'.

Oral cancer is strongly associated with chewing of tobacco. Oral cancer constitutes 20% of all cancers seen in India, whereas it is less than 1% in Western countries.
**Alcohol** intake increases the risk of oral, pharyngeal, esophageal and liver cancers. Diet high in **total fat** and cholesterol, increases the risk of colon, breast and prostate cancers.

An often asked question is, why only some smokers are getting cancer and not all smokers? **Glutathione-S-transferase** (GST) is involved in the detoxification of various carcinogens, including cigarette smoke. About 5% of population are lacking in GST. Smokers who are devoid of GST are more prone to develop lung cancer. There are 3 different genes and 3 iso-enzymes for GST.

**Promoters of Cancer**
Most carcinogens require promoters for the production of a cancer. Croton oil application on skin does not produce cancer. Croton oil application also does not lead to skin cancer. But when benzopyrene application is followed by croton oil, tumor is developed. In this case, croton oil is termed as the promoter. The active agent in croton oil is a phorbol ester, tetradecanoyl phorbol acetate (TPA). It activates Protein kinase-C. This results in phosphorylation of membrane proteins, leading to the triggering of malignancy. The carcinogen produces a mutation, but the promoter gives the drive for unchecked cell division.

**Progression**
The biological history of a tumor shows progression of malignancy. Cells with faster growth rate have a selection advantage. Thus cells with increased malignant character are progressively selected. Development of **familial adenomatous polyposis** is a good example for multistep progression. Mutations in the APC gene are inherited from parents. By the time the patient becomes adult, there will be different dysplastic aberrant crypts in the large intestine. Some of the cells will get somatic mutations in the K-Ras gene; these will progress to form adenomas. Further mutation in TGF gene or p53 gene or *Bax* gene will give the push for the development of malignancy.

**Action of Chemical Carcinogens**
Chemical carcinogens are usually ingested as procarcinogens. They are metabolised in the body, usually in liver, to become the active carcinogen, e.g. 2-acetyl amino fluoresce (AAF) when ingested, is metabolized to produce the ultimate carcinogen, sulfate ester of N-hydroxy-AAF. The enzymes responsible for the activation of procarcinogens are cytochrome P-450 system (Chapter 37). On the other hand, **direct carcinogens** are the ones which interact directly with the target molecules, e.g. methyl cholangrene.

Mechanisms of action of chemical carcinogens are: (a) Carcinogens are generally electrophiles (molecules deficient in electrons); they readily attack nucleophilic (electron rich) groups of DNA. (b) Carcinogens may bind covalently to cellular DNA. N2, N3, and N7 atoms of guanine are highly prone to addition of carcinogen groups. (c) These changes will lead to DNA alterations, in spite of DNA repair, with increased probability of mutations. Chemical carcinogens may produce the cancer: (a) At the sit of exposure, e.g. buccal cancer in tobacco chewers, skin cancer in tar workers. (b) At the site of metabolism, e.g. liver cancer produced by aflatoxin. (c) At the site of elimination, e.g. bladder cancer in persons working with aromatic dyes.

**Physical Carcinogens**
X-ray, gamma-ray and UV-ray may cause: (a) formation of pyrimidine dimers, (b) apurinic sites with consequent break in DNA, and (c) formation of free radicals and superoxides which cause DNA break, leading to somatic mutations. Exposure of X-ray in fetal life will increase the risk of leukemia in childhood. In population studies, 1 rad per year will increase the cancer incidence by 40/ million people per year.

**Antimutagens**
i. These are substances which will interfere with tumor promotion. **Vitamin A** and carotenoids are shown to reverse precancerous conditions.

ii. **Vitamin E** acts as an antioxidant, preventing the damage made by free radicals and superoxides.

iii. **Vitamin C** regularly given to persons working with aniline prevented the production of new cancer cases.

iv. Tubers, beans and leafy **vegetables** are shown to interrupt tumor promotion.

v. **Curcumin**, the yellow substance in Turmeric is known to prevent mutations.

vi. The beneficial effect of the fiber content of the diet is described in Chapter 36. Low protein, low fat, diet decreases the risk of cancer in animal studies.

**ONCOGENIC VIRUSES**
Another etiological factor of carcinogenesis is the integration of viral genes into the host DNA. This is diagrammatically represented in Figure 51.5. The circularization of virus DNA will help in this process.
Thus the virus genes become part and parcel of the cellular DNA. The drive for multiplication by the virus genome overrules the regulatory checks and balances of the cellular mechanism. So, there is uncontrolled multiplication of the cells. This is called **transformation** by oncogenic virus.

Rous in 1911 demonstrated that sarcoma in avians can be transferred from one animal to another by injecting the soluble fractions. In 1944, Gross finally proved that viruses could be oncogenic. A homogenate of mice tumor was prepared, passed through bacterial filter, and the supernatant was injected into another mouse. A new tumor developed at the site of injection. Gross argued that the filtrate could contain only viruses (and not bacteria or cancer cells) which produce a tumor. After a long time, at the ripe age of 87, Rous was awarded Nobel Prize in 1966.

A list of important oncogenic viruses in animals is shown in Table 51.3. The list is only representative and is far from exhaustive. Simian virus (SV) is the virus producing lytic infection in monkeys. But in mice and hamsters, SV-40 when introduced, produces sarcoma. In 1930s, an aggressive form of lymphoma (cancer arising from lymphocytes) was seen as an epidemic in chicken in North America, wiping out almost two-third of the total poultry population. For the first time, a cancer was accepted to be transmissible. Soon, the Marek virus was isolated which was proved to be the etiologic agent. By the end of 1940s, an effective vaccine was prepared and the disease was controlled.

If cancers are produced by viruses in so many different species, could there be viruses oncogenic to human beings? A direct association of a virus with a human cancer is difficult to prove. Demonstration of a virus in a cancer tissue is not a proof, because the virus may enter after the cancer formation. On the other hand, the whole virus is not necessary for transformation. A list of possible oncogenic viruses in man is given in Table 51.4.

**Fig. 51.3.** zur Hausen showed that HPV is integrated into the host DNA of human cervical cancer cells. Host cell DNA is isolated, cut with restriction endo-nucleases, electrophoresed, and hybridized with radioactive probes of HPV DNA. The DNA from patients are seen to hybridize with virus probes, as shown +ve in the slide. Details of DNA hybridization are given in Chapter 55.

**Fig. 51.4.** HPV and host interaction. Left slide, HPV infects one cell in the basal layer in human uterine cervix. Middle slide, Within few weeks, HPV spreads to most of the cells; replicates, and a lesion is manifested. Some host cells will escape the infection. In 99% cases, the lesion subsides within 6 months to 2 years time. Right slide, in 1% cases, virus is integrated into the host DNA, remains dormant. After 10-30 years, cancer is developed. Here malignant cells are shown to break the basal layer and invade into surrounding tissues.

**Fig. 51.5.** Virus integrated into *E. coli* chromosome.
Box 51.1. Oncogenes and Oncogenes are Different

1. Oncogen is the chemical which produces cancer.
2. Oncogens are the chemicals that produce cancer.
3. Oncogene is the gene causing cancer.
4. Oncogenes are the genes causing cancer.
5. Oncogenes are written with small letters, and antioncogenes are written with capital letters.
6. The gene present in normal cell is named with prefix c- (to show that it is in the cell), whereas the corresponding gene present in the virus is denoted with prefix v- (standing for virus).

There is a strong possibility for a transmitting agent for the Burkitt’s lymphoma (BL). In 1969, Epstein reported that all the biopsies of BL when placed in tissue culture for some time, generated the viral particles which could be seen under electron microscope (Barr was the technician who first perfected this technique). The new virus was named as Epstein-Barr (EB) virus.

The lymphoma progression is through 3 different events. The first step is infection with EBV which specifically infects B lymphocytes. The B cells are now immortalized, that is, they can be cultured indefinitely in artificial medium. But they are still dependent on the B cell growth factor (BCGF) for proliferation.

The second step is the chromosome translocation, usually from chromosome 8 to 14, but sometimes from 8 to 2 or from 8 to 22. The chromosome 14 contains gene for immunoglobulin heavy chain, 2 contains gene for kappa light chain and 22 for lambda light chain. The transposing region in chromosome 8 contains the oncogene c-myc. This transposition of oncogenes to one of the Ig loci confers BCGF-independence; but these B cells can grow very slowly.

The third step is the activation of c-myc oncogene, with consequent malignancy. EBV is also strongly associated with Nasopharyngeal carcinoma (NPC) in Chinese. This is typically seen in Malaysia, where NPC is very rare in native people as well as in people of South Indian origin. But NPC is the most common cancer in people of Chinese descent in Malaysia. This is true in North East India also. In Nagaland, about 40% of total cancers constitute NPC, which may be associated with EBV.

Similarly, in chronic myeloid leukemia, deletion of short arm of chromosome 22, called Philadelphia (Ph) chromosome is seen in 80% cases. In the rest, there is translocation of 9 to 22 leading to activation of c-abl present in chromosome 9.

In Non-Hodgkin’s lymphoma, translocation of chromosome 14 to 18 is very common, involving the bcl-2 oncogene. The bcl-2 product suppresses programmed cell death (see apoptosis, Chapter 42) leading to tumor formation.

HPV (Human Papilloma Virus) has a circular double stranded DNA. More than 100 HPV types are known. HPV types 16 and 18 are associated with human uterine cervical cancer; they cause 70% of all cervical cancers. Harald zur Hausen (Nobel prize, 2008) showed the HPV DNA in the cancer cells. HPV infects epithelial cells in the cervical mucosa; the virus multiplies and lyases the host cells, causing a lesion. In 99% of such cases healing occurs within 6 months to 2 years. But in about 1% cases, the HPV DNA is integrated into some of the host cells. After about 10-30 years, these cells
Proto-oncogenes are regulatory genes

1. Oncogenes are normal constituents of cells
   i. These are genes capable of causing cancer. (Box 51.1). Michael Bishop and Harold Varmus, pioneers in the oncogene research were awarded Nobel Prize in 1989. A definite proof for an oncogene was first demonstrated in Rous sarcoma virus. The full virus produces sarcoma in avians but a strain of virus deficient in a particular gene, could not cause the disease. Hence this gene was named as sarcoma gene, abbreviated as src.
   ii. However, the same DNA sequences are available in normal avian cells also. This reveals that normal cells do contain DNA sequences similar to viral oncogenes.
   iii. To distinguish these two genes, they are denoted as V-src (viral gene) and C-src (cellular gene). The oncogenes present in normal cells are also called as proto-oncogenes.
   iv. Today, more than 100 human proto-oncogenes are known. They are located on specific chromosomes. A list of some important c-oncogenes is given in Table 51.5.
   v. Proto-oncogenes are important regulatory genes of the cells. In fact, viruses carry these genes accidentally picking them from the host cells.

2. Proto-oncogenes are regulatory genes
   i. Products of many oncogenes are polypeptide growth factors, e.g. sis gene produces platelet derived growth factor (PDGF). This factor is required for normal wound healing.
   ii. Some of the products act as receptors for growth factor, e.g. erb-B produces receptor for EGF (epithelial growth factor).
   iii. Some other oncogene products act on key intracellular pathways involved in growth control, e.g., src product, a membrane-bound enzyme, phosphorylates a specific tyrosine residue, leading to cascade activation of cellular events. Receptors for EGF, insulin, PDGF, etc. are also activated by src-product protein.
   iv. The c-oncogenes are under the control of regulatory genes, and expressed only when required. When virus enters, an extra-oncogene is inserted so as to produce continuous expression of the gene leading to uncontrolled cellular activity and malignant transformation. Proto-oncogene activation has been demonstrated in different types of human tumors.

3. Many factors activate oncogenes
   The oncogenes also provide an explanation for the multifactorial origin of cancer. Thus viruses, chemical carcinogens, chromosome translocations, gamma-rays, spontaneous mutations, and all such factors may converge into one biochemical abnormality, the activation of oncogenes leading to malignancy. This unified theory is depicted in Figure 51.7. Chromosomai translocation is described previously. Another cause for oncogene activation is point mutation.

   **Point Mutation of Proto-oncogene:** The ras gene produces a protein termed P21 (Mol. wt. 21,000) related to the GTPase, that suppresses the activity of adenyyl cyclase. Adenyl cyclase has a key role in cellular response to hormones (Chapter 44). C-ras oncogene product is a mutated version of P21. So, GTPase activity is decreased leading to continuous activity of adenyl cyclase.

   **Anti-oncogenes or Oncosuppressor Genes**
   These are the genes, which normally protect the individual from getting the cancer. When the gene is deleted or mutated, cancer results (Table 51.6). Anti-oncogenes are written with capital letters, whereas oncogenes are represented by small letters.

   A part of short arm of chromosome 17 was shown to be deleted in various human cancers. This region is now known to contain an oncossuppressor gene, called **p53**. It is so called because the gene encodes a phosphoprotein with molecular weight 53,000; with 375 amino acids in length. Arnold Levine in 1979 identified the p53. It blocks the cells that have damaged DNA by triggering the production of another protein p21, which blocks cell division until the damage is repaired. If the DNA damage is severe, p53 directs the cell to commit suicide by apoptosis program. It can complex with other transforming proteins generated by other oncogenic viruses. (e.g T antigen of SV 40; E6 of HPV-16). Most tumors have a complete absence of p53, whereas others show mutant nonfunctional p53. Normal p53 can suppress transformation ability of oncogenic viruses in vitro. It is also seen that p53 activates the expression of genes that suppress cell proliferation.

   Similarly **RB gene** encodes a protein designated as p105 (Molecular weight:105,000). This protein also is found to

</table>
suppress cell proliferation, and to prevent the activity of various oncogenes. Only when both alleles of the RB gene are deleted (homozygous), retinoblastoma results. Mechanisms of actions of p53 and Rb proteins are explained under cell cycle, in Chapter 42.

**Growth Factors**

Many of the oncogenes act through the production of growth factors. The growth factors generally cause mitosis or differentiation of target cells. These may be considered as local hormones. There are more than 100 growth factors; a few important ones are shown in Table 51.7. Fibroblast growth factor (FGF), hepatocyte growth factor (HGF), keratinocyte growth factor (KGF), vascular endothelial growth factor or vasculotropin (VEGF) are some other well-characterized growth factors. Some of them are described in Chapter 48. Interleukins and interferons are growth factors released by lymphocytes/macrophages (see Chapter 49).

**Differences between Normal and Tumor cells**

**Tumor Kinetics**

Cell cycle has been described in Chapter 42. The cell cycle is divided into G1, S, G2 and M phases, the cycle being completed within 18-24 hr. The cell cycle time is more or less same for normal cells and cancer cells. In a normal tissue, only 1% cells are in the dividing state. In cancer tissues, about 2-5% of cells are in the cell cycle and this number demarcates a mildly growing tumor (2%) from an aggressive one (5%). This difference is made use of in treatment. Cytotoxic drugs and radiation will kill the cells in the cell cycle, while sparing the resting cells.

**Doubling Time**

Growth of a tumor mass depends on: (1) Cellular proliferation. The proliferation coefficient is the ratio of cells in the cycle to the resting cells. The more the ratio, the more aggressive is the cancer. (2) Cell death by apoptosis, lack of oxygen or nutrition and destruction by immunological mechanisms. The doubling time is the time taken by a tumor to exactly double its mass, and is a constant for a particular growth over a long period. The tumor doubling time in human cancers varies widely between 10 days to 450 days, with a mean of about 100 days. Very rapidly growing tumors will need lesser days to double the volume. In the case of tumor with a doubling time of 100 days, the time taken for this growth to reach 1cm size from the initial mutated cell is about 8-10 years. Thus the tumor was present in the body for a considerable period before the clinical detection. The same fact explains the development of the secondaries several years after the treatment of the primary growth.

**Malignant Transformation**

When a normal cell has acquired malignant character, it is said to be transformed. For his pioneering work in transformation studies in tissue culture, Renato Dulbecco was awarded Nobel prize in 1975. In the cell culture, this is seen as alterations in morphology as well as changes in the alignment among the cells (Figs 51.6A and B). Normal cells form a monolayer, while cancer cells show multilayered appearance.

**Contact inhibition**

It is a characteristic of normal cells. If a cut is made in the skin, the cells from both sides start to multiply. This

</tbody>
</table>
multiplication is stopped when the cells come into contact. This is called contact inhibition. Adjacent cells form tight junctions through which cell to cell communication occurs. But in the case of cancer cells, tight junctions are rare, the property of contact inhibition is lost and adjacent cells continue to multiply to form multilayered or jumbled appearance.

**Anchorage Dependence**
Yet another malignant character is the loss of anchorage dependence in tissue culture system. Normal cells adhere firmly to the surface of the glass bottle, but cancer cells do not. Vinculin is a protein found in the focal adhesion plates, that is, the structures involved in adhesion between the cells as well as the basement in the case of normal cells. Oncogene product, especially tyrosine kinase, causes abnormal phosphorylation of vinculin. So, there is diminished adhesion to substratum as well as the rounded appearance of transformed cells (Fig. 51.6B).

**Sialic Acid and Sialylation**
Most cancer cells carry more negative surface charges on their cell surface than their normal counterparts. This abnormality is due to the higher N-acetyl neuraminic acid (NANA) content of the cancer cell membrane. Due to the higher content of negative charges the cancer cells tend to repel each other, resulting in lesser adhesiveness. Altered sialylation of cell surface glycoproteins and glycolipids is closely related to the malignant phenotype of cancer cells, including the metastatic potential and invasiveness. Human sialidases are indeed related to malignancy and may be potential targets for cancer diagnosis and therapy.

**Cell Fusion**
Cell fusion plays an essential role in fertilization, immune response, tissue repair, and regeneration. Cell fusion may contribute to the initiation and progression of cancer. Experimental and clinical studies suggest a potentially multifaceted involvement of cell fusion in different stages of tumor progression, including aneuploidy and tumor initiation, origin of cancer stem cells, multidrug resistance, and the acquisition and diversification of metastatic abilities.

**Metastasis and Secondaries**
Cancer cells have a tendency to disintegrate from the main mass and to disseminate to nearby or distant organs. This forms metastasis. The word cancer is derived from a Greek word meaning crab. The cells from the main cancer tissue migrate farther away, like the feet of a crab. The collagenase and stromolysin released by most cancers help in the penetration of cancer cells into surrounding areas.

**Metabolic Alterations in Cancer Cells**
Many cancer cells are shown to delete different enzymes or even whole metabolic pathways. Generally cancer cells thrive on minimal enzymes. A good example is that many tumors prefer anaerobic glycolysis and eliminate citric acid cycle enzymes. Warburg’s hypothesis is described in Chapter 9.
Another example is the deletion of asparagine synthetase in certain lymphomas.

Why Cancer Cells are Immortal?
One reason is that cancer cells have increased and persistent activity of telomerase, the enzyme that maintains the length of telomeres (end region of chromosomes). See Fig. 40.19.

Apoptosis
Programmed cell death is called apoptosis (see Chapter 42). It is a Greek word, meaning "falling of leaves". In normal organs, the number of cells newly produced will be equal to the number of cells dead. In those cells which are progressing to apoptosis, there will be condensation of chromatin, shrinking of cells, DNA fragmentation and finally disintegration of the cell. Examples of apoptosis mediating genes (suicidal genes) are c-fos, p53, Rb; and so they in turn are oncouspessor genes. By the same argument, apoptosis protecting genes are cancer producing genes, e.g. bcl-2 and other oncogenes.

Tumor Immunology
All forms of treatment of cancer (surgery, radiotherapy and chemotherapy) leave some residual cancer cells in the body. These are annihilated by the body's immune mechanism. All the effector arms of immunological mechanisms described in Chapter 49 are active against cancer cells. These are (a) T cells, (b) NK cells, (c) antibody dependent complement mediated lysis, (d) antibody dependent cell mediated cytolysis (ADCC), and (e) macrophages. Burnet (Nobel prize, 1960) had postulated that the major purpose of immunological system is the surveillance against spontaneously occurring cancer cells. In the tumor bearing host, appreciable level of immunological reaction against the cancer is detected. This is because of the presence of tumor associated antigens (TAA) on the surface of cancer cells.

Virally induced tumors show virus-specific antigens. The same virus may produce tumors in different species; but all of them carry same antigen. This is because the virus is integrated at specific regions of the DNA, causing the same alterations in all the instances.

Chemically induced cancers show individually specific antigens. The same carcinogen injected at two different sites of the same animal may produce two tumors, with distinct antigens. This is because chemicals react with DNA at random sites, causing mutations at different loci. Most of the human cancers show the emergence of oncofetal antigens.

Oncofetal Antigens
During the fetal life, a particular gene is active, and the product, a protein is therefore produced in the cell (Fig. 51.8). During the differentiation process, this gene is suppressed and therefore the protein is not present in adult cells. However, along with the malignant transformation, de-differentiation occurs, the gene is derepressed and the protein is again available in the cell. Such products are classified as oncofetal proteins. The best examples are the appearance of alpha-fetoprotein (AFP) in hepatomas and carcinoembryonic antigen (CEA) in colon cancers. They generally serve as tumor markers.

TUMOR MARKERS
They are also called as tumor index substances. They are factors released from the tumor cells, which could be detected in blood and therefore indicate the presence of the tumor in the body. They are useful for the following purposes.

a. For follow-up of cancer and to monitor the effectiveness of the therapy and also to detect the recurrence of the tumor (Fig. 51.8).

b. To facilitate detection of cancer. The presence of tumor marker suggests the diagnosis, but caution is to be taken to rule out other non-malignant conditions.

c. For prognosis. Serum level of the marker may indicate roughly the tumor load, which in turn indicates whether the disease is curable or not.

d. For localisation. Experimentally it is shown that radiolabeled antibodies against the marker will be fixed on the tissues producing the marker.

---

**Fig. 51.8. Oncofetal antigen**
Precautions: Tumor markers are sometimes elevated in nonmalignant conditions. Not every tumor will cause a rise in the level of its associated marker, especially in the early stages of some cancers. When a marker is used for cancer screening or diagnosis, the physician must confirm a positive test result by using imaging studies, tissue biopsies, and other procedures.

Clinically Important Tumor Markers

1. Alpha Fetoprotein (AFP)
In 1963, Abelev demonstrated AFP. Its molecular weight is 70,000 D. It is fetal albumin and has similarities with adult albumin. It is increased in the circulation of patients with hepatocellular carcinoma, germ cell tumors, teratocarcinoma of ovary and in pregnancy with fetal malformations of neural tube (Table 51.8). In adult males and nonpregnant females, normal value is less than 15 ng/L. A value of AFP above 300 ng/L is often associated with cancer, although levels in this range may be seen in nonmalignant liver diseases. Levels above 1000 ng/L are almost always associated with cancer (except in pregnancy). The gene for AFP is located in chromosome No. 4.

2. Carcinoembryonic Antigen (CEA)
CEA level is markedly increased in colorectal cancers. Its molecular weight is 1,85 kD (Table 51.8). In 1965, Gold and Freedman identified the CEA. Over 50% of persons with breast, colon, lung, gastric, ovarian, pancreatic, and uterine cancer have elevated levels of CEA. CEA levels may also be elevated in inflammatory bowel disease (IBD), pancreatitis, and liver disease. Heavy smokers and about 5% of healthy persons have elevated plasma levels of CEA.

3. Beta Chain of Chorionic Gonadotropin
Beta-HCG is synthesised by normal syncytiotrophoblasts (cells of placental villi). Its molecular weight is 45 kD. HCG is a glycoprotein; it has alpha and beta subunits. The alpha subunit is identical with those of FSH, TSH and LH. The beta subunit is specific for HCG. It is increased in hydatidiform mole, choriocarcinoma and germ cell tumors (Fig. 51.9.). About 60% of testicular cancers secrete hCG. Normal value is less than 20 IU/L for males and non-pregnant females. Greater than 100,00 IU/L indicates trophoblastic tumor.

4. Cancer Antigen 125 (CA-125)
CA-125 is a tumor maker for ovarian cancers. It is a glycoprotein with a molecular weight of 10 million; one of the biggest molecules identified. The name is so given because it reacted with a monoclonal antibody, originally termed as OC-125 (Bast, 1981). Approximately 75% of persons with ovarian cancer will have elevated serum levels. (50% of persons with stage I disease and 90% with stage II). Elevated levels of CA-125 are also found in approximately 20% of persons with pancreatic and digestive tract...
cancers. CA-125 levels correlate with tumor mass; consequently, this test is used to determine whether recurrence of the cancer has occurred following chemotherapy. Normal blood level of CA125 is less than 35 U/mL.

5. Tissue Polypeptide Antigen (TPA)
It was isolated by Bjorklund in 1957. It is a common human carcinoma antigen, produced during G2 phase and released into surrounding fluids during mitosis. It is not specific for cancer of a particular site; but it is useful to assess the activity of the tumor. It is seen in blood as long as the tumor cells proliferate. The TPA blood test is sometimes used along with other tumor markers to help follow patients being treated for lung, bladder, and many other cancers.

6. Prostate Specific Antigen (PSA)
Chu isolated it in 1980. It is produced by secretory epithelium of prostate gland. It is normally secreted into seminal fluid, where it is necessary for the liquefaction of seminal coagulum. It is a 32 kD glycoprotein. It is a protease, and in serum it is seen complexed with alpha-1-antitrypsin. The PSA level, especially the complexed form, is increased in prostate cancers. PSA has been found to be elevated in 60-70% patients with cancer of the prostate. Most PSA is bound to antitrypsins in plasma but some PSA circulates unbound to protein (free PSA). Normal blood level of total PSA is less than 4 ng/L. Persons with a borderline total PSA (between 4-10 ng/L), but who have a low free PSA are more likely to have malignant prostate disease.

Other Tumor Markers used occasionally

Estrogen Receptor (ER)
ER is a protein found in the nucleus of breast and uterine tissues. The level of ER in the tissue is used to determine whether a person with breast cancer is likely to respond to therapy with tamoxifen, which binds to the receptors blocking the action of estrogen. Women who are ER-negative have a greater risk of recurrence than women who are ER-positive. Less than 6 femtomol/mg protein is negative; greater than 10 fmol/mg protein is positive.

Progesterone Receptor (PR)
PR consists of two proteins, which are located in the nuclei of both breast and uterine tissues. PR has the same prognostic value as ER, and is measured by similar methods. Tissue that does not express the PR receptors is less likely to bind estrogen analogs used to treat the tumor. Persons who test negative for both ER and PR have less than a 5% chance of responding to endocrine therapy. Those who test positive for both markers have greater than a 60% chance of tumor shrinkage when treated with hormone therapy. Normal value is less than 6 femtomol/mg protein. Greater than 10 fmol/mg protein is positive.

Nuclear Matrix Protein (NMP22)
NMP22 is a structural nuclear protein that is released into the urine when bladder carcinoma cells die. Approximately 70% of bladder carcinomas are positive for NMP22.

Bladder Tumor-associated Analytes (BTA)
BTA is comprised of type IV collagen, fibronectin, laminin, and proteoglycan, which are components of the basement membrane that are released into the urine when bladder tumor cells attach to the basement membrane of the bladder wall. These products can be detected in urine using a mixture of antibodies to the four components. BTA is elevated in about 30% of persons with low-grade bladder tumors and over 60% of persons with high-grade tumors.

Beta-2-Microglobulin (B2M)
B2M blood levels are elevated in multiple myeloma, chronic lymphocytic leukemia (CLL), and some lymphomas. Levels may also be higher in some non-cancerous kidney disease. Normal levels are usually below 2.5 mg/L. B2M is useful to help predict the long-term prognosis in these cancers. Patients with higher levels of B2M usually have a poorer prognosis. B2M is also checked during treatment of multiple myeloma to see how well the treatment is working.

Bladder Tumor Antigen (BTA)
BTA is found in the urine of many patients with bladder cancer. It may be seen in some non-cancerous conditions such as kidney stones or urinary tract infections. It is sometimes used along with NMP22 to test patients for the recurrence of bladder cancer. This test is not often used.
Calcitonin
It is a hormone produced by cells called parafollicular C cells in the thyroid gland (see Chapter 35). It normally helps regulate blood calcium levels. Normal calcitonin levels are below 5 to 12 pg/ml (picograms per milliliter) (A picogram is 10^{-12} of a gram.) In medullary thyroid carcinoma (MTC), a cancer of parafollicular C cells, blood levels of calcitonin are often greater than 100 pg/ml. This is one of the rare tumor markers that can be used to help detect early cancer. Because MTC is often inherited, blood calcitonin can be measured to detect the cancer in its very earliest stages in family members who are known to be at risk.

HER2/neu (or erbB-2, or EGFR2)
HER2 is a protein that stimulates breast cancer cells to grow. Higher than normal levels can be found in some other cancers, too. The HER2 level is usually found by testing a sample of the cancer tissue itself, not in blood. HER2 test is positive in about 1 in 5 breast cancers. These cancers tend to grow and spread more aggressively than other breast cancers. All newly diagnosed breast cancers should be tested for HER2. HER2-positive cancers are more likely to respond to certain treatments such as trastuzumab (Herceptin) and lapatinib (Tykerb), which work against the HER2 receptor on breast cancer cells.

Neuron Specific Enolase (NSE)
NSE is a marker for neuroendocrine tumors such as small cell lung cancer, neuroblastoma, and carcinoid tumors. It is most useful in the follow-up of patients with small cell lung cancer or neuroblastoma. Elevated levels of NSE may also be found in some non-neuroendocrine cancers. Abnormal levels are usually higher than 9 ìg/ml (micrograms per milliliter).

Thyroglobulin
Thyroglobulin is a protein synthesised by the thyroid gland. Thyroglobulin levels are elevated in many thyroid diseases, including some common forms of thyroid cancer. Treatment for thyroid cancer often involves removal of the entire thyroid gland. Thyroglobulin levels in the blood should fall to undetectable levels after treatment. A rise in the thyroglobulin level may indicate the recurrence of cancer. In some persons, antithyroglobulin antibodies may be present in circulation, which can affect test results. This is why levels of anti-thyroglobulin antibodies are often measured at the same time.

Paraproteinemias and multiple myeloma are described in Chapter 49. Oncofetal proteins and tumor markers are listed in Table 51.8.

**ANTICANCER DRUGS**
Surgery and radiotherapy are most effective to reduce the initial tumor load. These are the prime modalities of treatment in solid tumors. Chemotherapy is the sheet anchor of therapy in leukemias, advanced lymphomas, choriocarcinoma and other widely disseminated malignancies. The effectiveness of cytotoxic drugs is directly proportional to the doubling time of the tumors, and is inversely proportional to the number of cancer cells. Cytotoxic drugs affect all the cells which are in the dividing phase. Rapidly dividing normal cells (gastrointestinal tract, hematopoietic system, hair follicles, gonads) are also affected by chemotherapeutic drugs, leading to toxicity. In fact, pharmacological dose and toxic dose usually overlap in the case of these drugs.

</table>
Cell destruction by cytotoxic drug follows the first order kinetics, that is, it reduces a constant percentage and not a constant number of cancer cells. This is explained in the Chapter 53 (Table 53.3). The same dose, which reduces the cancer cells from $10^8$ to $10^7$, is required to reduce them from $10^3$ to $10^2$. Therefore, it is difficult to eradicate the residual cancer cells by chemotherapy. These are lysed by the immune mechanisms, when a complete cure is achieved. Common anticancer drugs are listed in Table 51.9.

**Methotrexate**

It inhibits dihydrofolate reductase. Methotrexate has structural similarity to folic acid, and hence will competitively inhibit folate reductase (Fig. 51.10). So in presence of methotrexate, tetrahydrofolic acid is not produced, which is necessary for incorporation of C2 and C8 of purines and C5 methyl group in thymidine. Thus there is inhibition of DNA synthesis and consequently of cell division. Methotrexate is commonly employed in the treatment of choriocarcinoma, which is a curable cancer. It is also useful in acute leukemia, where highly toxic doses are first administered so as to kill maximum number of leukemia cells, and then patient is retrieved by citrovorum factor (folinic acid).

**6-Mercaptopurine**

It is a purine analog (Fig. 51.11, upper part). It is activated into 6-mercaptopurine ribotide, which prevents amination of IMP to AMP, so that the availability of AMP is reduced (Fig. 39.13). This leads to inhibition of synthesis of DNA, and in turn cell division. It is commonly employed in treating acute lymphoblastic leukemia.

**Thioguanine**

It is also a purine analog (Fig. 51.11, middle). The mechanism of action is more or less similar to that of 6-mercaptopurine.

Both these drugs were developed by Gertrude Elion and George Hitchings; both were awarded Nobel prize in 1988.

**5-Fluorouracil**

It is an analog of uracil or can be considered as an analog of thymine. Fluorouracil will inhibit thymidylate synthase, thereby reducing the conversion of dUMP to dTMP (Fig. 39.20). Thereby thymine incorporation in the DNA, and consequent DNA synthesis are prevented. The drug is widely used in the treatment of adenocarcinoma of colon and breast.

**Cyclophosphamide**

It is a nitrogen mustard derivative. It is extensively used in different cancers, especially lymphomas and myeloid leukemias. It is an alkylating agent, causing cross linkage between adjacent bases of the double helix. Nitrogen of guanine is especially attacked. Thus DNA strands cannot separate out, and new DNA synthesis is blocked.

**Mitomycin C**

It is derived from sterptomyces. The drug causes cross bridge between DNA strands, preventing separation of strands, and inhibiting new DNA synthesis. It is used in adenocarcinomas of stomach, breast, colon, etc.
Vincristine and Vinblastine
They are alkaloids isolated from the leaves of the garden plant, periwinkle or *vinca rosea*. Indian medicine had been using this plant from time immemorial. In 1949, Robert Noble found that an extract of periwinkle leaves reduce the WBC count in leukemic rats. In 1954, Noble isolated the vincristine, out of about 300 different alkaloids present in the leaves. From one ton of leaves, only 1 mg of the active ingredient could be isolated. In 1958, Irving Johnson first established the clinical usefulness of the drug in human leukemias. The drugs are now widely used in leukemias, lymphomas as well as in solid tumors. It has stathmokinetic (spindle movement) inhibitory effect. So, the cells are arrested in metaphase and cell division is inhibited.

Azaserine
It is a derivative of serine, diazo acetyl serine. The structure of azaserine is shown in Figure 15.11, under serine metabolism. It is a glutamine analog. So it will block the reactions in which glutamine takes part. So, the following reactions are inhibited: phosphoribosyl amine synthesis (step 1 purine synthesis, Fig. 39.12); formyl glycinamidine ribonucleotide (step 4 of purine synthesis, Fig. 39.12); and guanosine monophosphate synthesis (Fig. 39.14). Thus purine synthesis and thereby DNA synthesis are inhibited.

L-asparaginase
It is an enzyme useful in the treatment of lymphomas and leukemias. It will convert asparagine to aspartic acid by removing one molecule of ammonia. When asparagine is injected, blood asparagine level is lowered. Asparagine starvation will destroy cancer cells, which are deficient in asparagine synthetase. However, normal cells are spared because they contain asparagine synthetase, so that asparagine can be synthesised from aspartic acid (see Fig. 16.3).

Drug Resistance
The mechanisms of drug resistance include:
1. The target enzyme or pathway is deleted.
2. Alternate minor pathways for drug catabolism are opened.
3. Drug uptake is reduced or inhibited. Multi-drug resistance in cancer chemotherapy is due to over-expression of a membrane protein, called P-glycoprotein (Pgp). This acts as an efflux pump of drugs. It pumps hydrophobic drugs out of the cell by an ATP dependent process (ABC protein), thereby reducing their cellular concentration. This leads to resistance for many anticancer drugs.
4. Increased synthesis of enzymes degrading the drug. Methotrexate is a good example. Methotrexate inhibits dihydro folate reductase. When methotrexate is given, tumor cells increase 400 times the synthesis of the enzyme. This is by gene amplification. The amplified genes, measuring up to 1000 kbp could be detected as homogeneously staining regions in the chromosome.

Tissue Proteins in Health and Disease

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Collagen, structure and synthesis
2. Abnormal collagens
3. Elastin
4. Keratins
5. Muscle proteins
6. Myosin, Actin, Troponins
7. Lens proteins and cataract
8. Biochemistry of ageing
9. Prions and Alzheimer’s disease

COLLAGEN
The major structural protein found in connective tissue is the collagen. Collagen is a Greek word which means the substance to produce glue. It is the most abundant protein in the body. About 25-30% of the total weight of protein in the body is collagen. It serves to hold together the cells in the tissues. It is the major fibrous element of tissues like bone, teeth, tendons, cartilage and blood vessels.

Structure of Collagen
The tropocollagen, has a molecular weight of 285 kDa. The tropocollagen is made up of three polypeptide chains. Depending on the amino acid variations, there are 19 types of collagens described. Type I is the most abundant form, seen in connective tissues in almost all regions of the body. Type II is mainly seen in cartilage and vitreous humor, Type III is seen in skin, lung and vascular tissues and Type IV is seen in the basement membranes. Others are seen in minor quantities. About 30 genes are responsible for collagen synthesis, and the enzymes necessary for collagen synthesis.

Each polypeptide chain of collagen has about 1000 amino acid residues. The amino acid composition of collagen is quite unique. About 33% of the amino acids is glycine, that is, every third residue is glycine. The repetitive amino acid sequence may be represented as Gly - X - Y - Gly - X - Y - ; where X and Y are other amino acids, most commonly proline and hydroxy proline. Moreover, 4-hydroxy proline, 3-hydroxy proline and 5-hydroxy lysine are found in fairly large proportions in collagen. The hydroxylated amino acid residues are of special functional significance.

Synthesis of Collagen
The collagen is synthesized by fibroblasts intracellularly, as a large precursor, called procollagen (molecular weight 360 kDa). It is then secreted. The extracellular procollagen is cleaved by specific peptidases to form tropocollagen.

Post-translational Modifications
The hydroxylation of proline and lysine residues of collagen is a post-translational modification taking place intracellularly. Prolyl hydroxylase and lysyl hydroxylase are both dioxygenases using molecular oxygen. The enzyme also contains ferrous iron at its active site and requires a reducing agent like ascorbic acid to preserve the iron in the reduced ferrous state. So, vitamin C deficiency leads to poor hydroxylation. It is the major biochemical defect in scurvy (Chapter 34). The hydroxylation is site specific. Proline is hydroxylated in position 4. Lysine is hydroxylated in position 5.

Glycosylation of Procollagen
The hydroxylated polypeptides are next glycosylated. The common carbohydrate residues added are galactose and glucose, which are added sequentially by galactosyl and glucosyl transferases. The glycosylation occurs only on the hydroxy lysine residues. The extent of glycosylation is different in various sites, e.g. tropocollagen in tendons has only 6 carbohydrate residues, whereas in the lens capsule there are about 110 units.
**Type IV collagen** is an exception; the triple helices are discontinuous. Type IV is mainly seen in basement membranes, where it produces mesh-like formation.

When a solution of collagen is boiled, the viscosity of the solution decreases. The native rod-like structure is altered and a protein, with random coil structure results. It is then called **gelatin**.

**Quarter-Staggered Arrangement**
The tropocollagen molecules are arranged in a 'quarter staggered array' to form the collagen fibers (Molecules in each row separated by 400 Å and adjacent rows by 680 Å). The structure repeats after each row (Fig. 52.2). Thus, the collagen fiber has **triple stranded, quarter staggered** arrangement. This arrangement helps in mineralization.

**Cross-Links in Collagen Fibers**
The collagen fibers are strengthened by covalent cross-links between lysine and hydroxylysine residues. The cross-links are formed by **lysyl oxidase** which converts these amino acids into aldehydes. These are called **aldol cross links**. Lysyl oxidase is a copper containing enzyme, the copper ion being located at its active site. Box 52.1 gives a summary of the steps in collagen formation.

In **copper** deficiency, reduced cross-linking of collagen results (Chapter 35). The aldehyde derivatives of lysine residues can form an aldol condensation. Such aldol cross links are formed near the amino terminal of the chains.

The older the collagen, the more the extent of cross linkages. The process continues, especially in **old age**, so that the skin, blood vessels and other tissues become less elastic and more stiff, contributing a great extent to the medical problems of the old people.

**Functions of collagen**
1. To give support to organs.
2. To provide alignment of cells, so that cell anchoring is possible. This in turn, helps in proliferation and differentiation of cells.

3. In blood vessels, if collagen is exposed, platelets adhere and thrombus formation is initiated.

**Degradation of Collagen**

Collagenases are enzymes that can degrade collagen. Collagen is a protein resistant to attack by ordinary enzymes. The collagenase produced by *clostridium histolyticum*, the pathogen responsible for producing gas gangrene splits each polypeptide chain at the site indicated; \( \text{X} \downarrow \text{Gly - Pro - Y} \). This bacterium can destroy connective tissue barriers and this accounts for its invasiveness. Tissue collagenases are active in animals whose tissues have to undergo a great degree of remodelling, e.g., tadpoles. Adult human tissues do not have any appreciable amount of collagenase activity.

Degradation of collagen is seen when there is bone and cartilage resorption, osteoporosis, tumor metastasis, during postpartum involution of uterus, Paget’s disease, rickets, osteoarthritis, rheumatoid arthritis, and scurvy.

**Abnormalities in Collagen**

1. **Osteogenesis Imperfecta**
   It is inherited as a dominant trait. It is the result of a mutation which results in the replacement of a single glycine residue by cysteine (or other bulkier amino acid) in Type I collagen. Over 100 different types of mutations in the gene are reported. This change disrupts the triple helix near the carboxy terminus, hence the polypeptide becomes excessively glycosylated and hydroxylated. So, unfolding of the helix takes place and fibrillar array cannot be formed. This results in brittle bones leading to multiple fractures and skeletal deformities.

2. **Ehlers-Danlos Syndrome (EDS)**
   It is due to defective type III collagen formation due to defective lysyl oxidase or lysyl hydroxylase. It is characterized by weakening of collagen, loose skin, hypermobile and lax joints. Hyperextensibility of skin and joints are the hallmark of this condition. 10 different types of this disease are described. In Type 4 EDS, the type III collagen is abnormal. In Type 6 EDS, lysyl hydroxylase is absent.

3. **Alport Syndrome**
   Type IV collagen is abnormal, so basement membrane of kidney glomerular apparatus is abnormal. Hence, hematuria is seen, which will eventually progress to kidney failure.

4. **Epidermolysis bullosa**
   Type VII collagen (otherwise called anchoring fibril) is abnormal due to mutations in the gene. Skin blisters and breaks are observed.

5. **Marfan’s Syndrome**
   It is inherited as autosomal dominant manner. Arachnodactyly (long digits), ectopia lentis (dislocation of lens), hyperextension of joints, aortic aneurysm are manifestations. A defect in the gene, coding for a connective tissue protein, *fibrillin-1*, leads to this disease. The gene for fibrillin-1 is on chromosome 15. Fibrillin-1 is a glycoprotein, with a molecular weight of 350 kDa. It is a component of microfibrils, which normally gives the substratum for deposition of elastin. So, fibrillin and elastin are deposited in lower concentrations. Closely related protein, fibrillin-2 is produced by a gene present on chromosome 5. Mutation in fibrillin-2 leads to congenital contractural arachnodactyly.

6. **Menke’s Disease**
   Deficiency of copper results in defective function of lysyl oxidase, and reduced cross linking of collagen results (See Chapter 35).

7. **Deficiency of Ascorbic Acid**
   It is characterized by defective hydroxylation of collagen. The collagen formed is weak, leading to fragility of blood vessels, poor wound healing, etc (see Chapter 34).

8. **Homocystinuria**
   The accumulated homocysteine in this condition, reacts with lysyl aldehydes to block cross linking. The skeletal deformities, vascular and ocular defects are thus produced (Chapters 15 and 25).

9. **Lathyism**
   It is due to ingestion of lathyrus sativa or sweet pea. It is due to a toxic agent beta oxalyl amino alanine (Chapter 36). This compound has been found to inhibit lysyl oxidase. This would interfere with formation of lysyl cross linking.

**ELASTIN**

Elastin is a protein found in connective tissue and is the major component of elastic fibers. The elastic fibers can stretch and then resume their original length. They have high tensile strength. They are found in the ligaments as well as in the walls of the blood vessels, especially large vessels like aorta. One third of the residues are glycine. Proline is present in large amounts, so also alanine. Hydroxyproline is present in small amounts while hydroxylysine and glycosylated hydroxylysine are absent. Triple helix structure is also absent. When elastin matures, desmosine cross links are formed from 4 lysine residues. (Collagen has aldol cross links, while elastin has desmosine cross links). Once mature, elastin is very stable; the turn over rate is very low.
Williams-Beuren syndrome: The gene for elastin is in chromosome 7. Deletion of this gene leads to a clinical condition called Williams-Beuren syndrome with severe developmental abnormalities in connective tissues all over the body.

Pseudoxanthoma elasticum: It is an inherited defect in the formation of elastin. Clinical manifestations are similar to Ehlers-Danlos syndrome.

Copper deficiency: Copper deficiency blocks the formation of aldehydes, which are essential for cross linking. Some lysine residues are oxidized by copper containing lysyl oxidase and the resulting aldehyde derivative can condense with an unmodified lysine to form lysino-norleucine. The elastic nature of elastin fiber is due to these different cross links.

Fibronectin
Fibronectin is a cell surface protein that is involved in the interaction of cells with the extracellular matrix. It has been found to play key roles in cell adhesion, cell migration, blood clotting and wound healing. Deficiency of fibronectin in tumor cells account for their lack of adhesive properties and chances of metastasis (Chapter 51). Plasma fibronectin is produced by hepatocytes and secreted into blood stream. Cellular fibronectin is produced by fibroblasts. Fibronectin has binding sites for collagen, integrin, heparin, fibrin, DNA and cell surface. The fibronectin binds to cells through the integrins present on the cell surfaces. Fibronectin receptor interacts with actin microfilaments present in the cytosol. Fibronectin is a glycoprotein, is a dimer, each subunit has molecular weight of 230 kDa.

Laminin
It is a basement membrane protein with adhesive properties that enable epithelial cells to fix to underlying connective tissue. It is the first extracellular matrix protein manifested during embryogenesis. It has a vital role to play in neuronal outgrowth and nerve regeneration. It is a glycoprotein with three polypeptide chains. High levels of laminin have been reported in patients suffering from Alzheimer's disease. Increased expression of laminin is associated with senile plaques and amyloid proteins.

Keratins
Keratins are proteins present in hair, skin and nails, horn, hoof, etc. The fibers present are called alpha keratins and matrix as keratohyalin. They mainly have the alpha helical structure. Each fibril has 3 polypeptide chains and each bundle has about 10-12 fibrils. The keratohyalin matrix has cysteine-rich polypeptide chains which are held together by disulfide bonds. The more the number of disulfide bonds, the harder the keratin is. Moreover, covalent bonds are also seen between lysine and glutamic acid residues of adjacent polypeptide chains, forming amide bonds (similar to formation of hard clot).

The keratin present in hair has significantly more number of disulfide bonds, which give the mechanical strength. On disrupting these bonds by reduction, the solubility increases, while the tensile strength decreases. This is used in artificial waving of hair.

Contractile Proteins
Movement is an important property of life, especially of the members of the animal kingdom. The organism may move as a whole (walking) or movement of cells may occur (diapedesis or sperm movement) or it may occur at the subcellular level (transfer and exocytosis of secretory proteins). The important contractile proteins are actin and myosin in muscles. Beating of cilia or sperm is achieved by tubulin and dyenin. Tubulin, actin, microfilaments, kinesin, and intermediate filaments are involved in the movement of secretory granules from their site of production to their release.

Kartagener's syndrome
Absence of dyenin in cilia and flagella results in immotile cilia and flagella. This will lead to chronic respiratory infection and male infertility.

MUSCLE PROTEINS
Striated muscle is made up of multinucleated cells bound by plasma membrane called sarcolemma. Sarcomere is the functional unit of muscle. Each muscle cell contains myofibrils about 1 mm in diameter. The myofibrils are immersed in a cytosol that is rich in glycogen, ATP, creatine phosphate and glycolytic enzymes.

The functional unit of a myofibril is a sarcomere. The dark A bands and light I bands alternate regularly (See Fig. 52.3). The central H zone of A band is lighter, while the dark M line is found in the middle of the H zone. The I band is bisected by a very dense narrow Z line.

Fig. 52.3. Sliding and shortening of actin and myosin is the basis of muscle contraction. Compare the distance between Z lines in the upper and lower pictures.
These bands are formed by variable combination of thick and thin filaments (Fig. 52.3). The thick filaments have a diameter about 150 Å whereas thin filaments have a diameter about 70 Å.

The thick filament is primarily myosin and thin filament contains actin, tropomyosin and troponin. The Z line contains 2 actin molecules and M protein is located in the M line (Fig. 52.3).

Thick and thin filaments slide past each other during the muscle contraction, so that the muscle shortens by as much as a third of its original length. However, the lengths of the thick and thin filaments do not change during muscle contraction (Fig. 52.3). The mechanism is explained in Figure 52.4.

**Myosin**

Myosin has 3 different biological activities:

- **a.** Myosin molecules assemble into filaments.
- **b.** Myosin acts as the enzyme ATPase.
- **c.** Myosin binds to actin polymer which is the major component of the thin filaments.

Myosin molecules are large (about 540 kD), each with 6 polypeptide chains; 2 identical heavy chains and 4 light chains. The myosin molecule has a double headed globular end. They are joined to a long double stranded alpha helical coil formed by the heavy chain. At the head portion of each heavy chain, 2 light chains are bound. The heavy chain is thus demarcated into an amino terminal globular head and C-terminal tail (Fig. 52.5). Part of the amino acid sequence in the heavy chain is similar to that at the active site of other ATPases.

Trypsin cleaves myosin into 2 parts; light meromyosin (LMM) and heavy meromyosin (HMM) types (Fig. 52.6). The LMM can form filaments but has no enzymatic activity. HMM has enzymatic activity and binds actin, but cannot form filaments. HMM can further be split into the S1 fragments having the ATPase site plus the actin binding site and the S2 subfragment.

**Fig. 52.4.** During muscle contraction, myosin moves over actin filament

**Fig. 52.7.** Cycle of events in muscle contraction
Box 52.2. Muscle Contraction-relaxation Events

1. Nerve impulse releases acetylcholine (ACh) at motor end-plate. This ACh binds with the receptors.
2. Sodium-potassium conductance in neuro-muscular end-plate, so that a potential is generated at the end-plate.
3. This is transmitted as the action potential in muscle fibers.
4. Depolarization; release of calcium ions from SR
5. Binding of calcium ions to TnC.
6. Cross-link formation between actin and myosin
7. Sliding of thin filaments over thick filaments; muscle is contracted.
8. Calcium is pumped back into SR.
9. Release of calcium from troponin.
10. Actin and myosin are separated; muscle relaxed.

Actin
It is the major protein of the thin filaments. It is a monomeric protein often referred to as G-actin due to its globular shape. It can polymerise into a fibrous form, called F-actin, which is a helix of actin monomer.

The muscle contraction results from interaction of actin and myosin, to form actomyosin, with energy provided by ATP. When the two thin filaments that bind the cross bridges of a thick filament are drawn towards each other, the distance between Z lines becomes shorter (Figures 52.3 and 52.4). This is transmitted as the action potential in muscle fibers. This needs energy from hydrolysis of ATP, effected by the ATPase activity of myosin. The cyclical events are depicted in Figure 52.7.

The contractile force is generated by conformational changes, leading to dissociation of actin and S1 heads of myosin. There is a reversible attachment and detachment of myosin S1 head to actin. This is due to the hinge like movements between the domains of myosin.

Troponins
The muscle contraction is modulated by troponin and tropomyosin through Ca++ which is the physiological regulator of muscle contraction. In the resting muscle, the Ca++ is within the sarcoplasmic reticulum. The nerve impulse releases Ca++ from the sarcoplasmic stores and increases its cytosolic concentration about 10 times (1 mM to 10 mM). The action of calcium is brought about by 2 proteins, troponin complex and tropomyosin located in the thin filament.

The troponin complex has 3 different polypeptide chains. Out of this, troponin-C (TnC, 18 kD) binds calcium. Troponin-I (TnI, 21 kD), otherwise called "actomyosin-ATPase inhibitory element", binds to actin and inhibits binding of actin to myosin. Troponin I is a marker for myocardial infarction (Chapter 23). Its level in serum is increased within 4 hours of myocardial infarction, and remains high for about 7 days. It is about 75% sensitive index for myocardial infarction. The cardiac form of TnI is 31 amino acids longer than the skeletal muscle form of TnI. Cardiac isoform of TnI has a molecular weight of 24 kD.

Troponin-T (TnT, 37 kD) binds to tropomyosin. Two isoforms of cardiac TnT, called TnT1 and TnT2 are present in adult human cardiac tissue. Serum levels of TnT2 increases within 4 hours of myocardial infarction, and remains high for up to 14 days. The TnT2 is 100% sensitive index for myocardial infarction.

The TnC has both high affinity (C-terminal) and low affinity (N-terminal) calcium binding sites. TnC has calmodulin like properties. In the resting muscle, only the high affinity sites are occupied by Calcium, but when Ca++ is released from sarcoplasmic reticulum, low affinity sites are also occupied by Ca++. This results in a conformational change that is transmitted to tropomyosin. This shift in position of tropomyosin alters the binding of actin to S1. The events may be depicted as

\[
Ca^{++} \rightarrow \text{troponin} \rightarrow \text{tropomyosin} \rightarrow \text{actin} \rightarrow \text{myosin}
\]

Transduction of Chemical Energy to Mechanical Energy
The amount of ATP in muscle is sufficient to sustain contractile activity for less than one second. The reservoir of high energy phosphate in skeletal muscle is creatine phosphate. The reaction (Lohman’s reaction) is catalyzed by Creatine Kinase (CK) (Chapter 23).

CK
Creatine phosphate + ADP ---\rightarrow ATP + Creatine

The \( \Delta G^0 \) of creatine phosphate is -10.3 kilocalories per mol, whereas that for ATP is only -7.3 kilocalories. Resting muscle has a high concentration of the creatine phosphate (25 mM) when compared to ATP (4 mM). The creatine phosphate is therefore able to provide a high ATP concentration during muscle contraction (In athletes, it is the major source of energy during the first 4 seconds of a short sprint).

During muscle contraction, the ATP level remains high as long as creatine phosphate is present. But following contractile activity, the levels of ADP and Pi rise. The reduced energy charge of active muscle stimulates glycogen breakdown, glycolysis, TCA cycle and oxidative phosphorylation. The red striated muscle has an active aerobic metabolism compared to white muscle.

In smooth muscle, the contraction is not regulated by the troponin-tropomyosin mechanism, but through calcium mediated phosphorylation of myosin light chains.

Calcium and Muscle Contraction
Sarcoplasmic reticulum (SR) regulates intracellular levels of calcium in skeletal muscle. In the resting state, calcium ions are pumped into the SR through Ca-ATPase. Inside the SR, calcium ions are bound with specific calcium-binding protein, called Calsequestrin. When nerve impulse excites the sarcolemma, the calcium channel is opened, calcium ions are released from SR into sarcoplasm. The calcium ion
The TnC-4Ca²⁺ complex attaches with TnI and TnT, which calcium binding sites of TnC are now saturated with calcium. The concentration in the cytoplasm is increased to 3000 fold. The calcium release channel is also known as the ryanodine receptor (RYR). The RYR1 is present in skeletal muscles and RYR2 in cardiac muscles. The receptor is so named because Ryanodine, a plant alkaloid could bind with the receptor. The channel is ligand-gated; calcium ions and ATP act synergistically. The sequence of events in the muscle contraction and relaxation are summarized in Box 52.2. Nitric oxide is a powerful muscle relaxant (See Chapter 16).

Inherited Diseases due to Abnormality of Proteins

In Malignant hyperthermia, halothane and succinylcholine (used in anesthetic practice) will cause high fever. Here calcium channels remain open, and so cytosolic calcium concentration remains high. The drug of choice in the treatment is dantrolene, which inhibits release of calcium from the sarcoplasmic reticulum, so that cytoplasmic calcium is kept at a reduced rate. In this condition, there are different mutations in the calcium release channel protein (RYR1 gene) or in DHPR gene (dihydro pyridine receptor, a voltage gated calcium channel).

Dystrophin is a structural protein, attached to muscle cell membrane. Dystrophin is part of a large complex, consisting of dystroglycan, laminin and sarcoglycans. Dystrophin links the actin of cytoskeleton of the cell into the extracellular matrix. Mutations in the dystrophin gene cause Duchenne muscular dystrophy or a milder form called Becker muscular dystrophy. Some forms of cardiomyopathy are also related to mutations in dystrophin. Mutations in sarcoglycans cause limb girdle dystrophy. Mutations in the genes for the glycosyl transferases (which add the sugar groups to proteins) are also responsible for some types of muscle dystrophies. Mutations in the cardiac myosin heavy chain cause familial hypertrophic cardiomyopathy.

**Cellular and Sub-cellular Movements**

In multicellular organisms, maintenance of the size and shape of the cell is essential for cellular function. At subcellular levels, transfer of secretory granules from its sites of production to the exterior of the cells is important (e.g. hormone secretion). Cells also need contractile proteins for self-propulsion (e.g. Leukocyte migration, movement of the sperms).

**Cytoskeleton**

The plasma membrane of a cell is anchored to the cytoskeleton. It is made up of a network of microfilaments and microtubules, and is responsible for the shape of the cell, its mobility and chromosomal movements. RBC cytoskeleton contains spectrin, a tetramer composed of alpha (240 kD) and beta (220 kD) polypeptides, as well as ankyrin (200 kD) which binds to spectrin. A meshwork of actin filaments and spectrin is attached to the plasma membrane by ankyrin. Spectrin and ankyrin are seen not only in RBCs, but in the microtubular network of a large variety of cells. Adducin, a calmodulin-associated protein increases spectrin binding to actin. In the muscle, dystrophin joins a sarcolemmal glycoprotein to the actin filament. (Dystrophin is deficient in Duchenne muscular dystrophy).

**Calmodulin**

It controls the contractile apparatus and cytoskeleton through calmodulin-binding proteins. Spectrin (erythrocyte) and spectrin-like proteins (brain and other tissues), are major members of the cytoskeleton. Tau protein (brain micro-tubules) and caldesmon (smooth muscle) are collectively referred to as flip-flop switch proteins. These proteins interact with calmodulin and cytoskeletal proteins (tubulin or actin). Calcium first binds calmodulin, that attaches to calmodulin-binding protein, which in turn connect with the target proteins in cytoskeleton. Calmodulin is a calcium-activated switch. It has 2 high affinity calcium binding sites. When calcium is bound, there is a conformational change in calmodulin; this exposes the active center. Calmodulin binds with myosin light chain kinase and phosphorylase kinase of glycogen degradation (Fig. 9.38).

**Microfilaments**

Main constituent of the microfilaments is actin. Actin may occur as monomer (G) or polymer (F), depending on the ratio of ATP/ADP in the cells. Polymerization of actin occurs in the presence of Mg⁺⁺ and K⁺ ions. Repeated dissociation and reassembly of actin is essential for cell motility.

**Microtubules**

Intracellular movement of the secretory granules is achieved by microtubular system. These consist of alpha and beta tubulins. The functions include formation of mitotic spindle, and movement of secretory granules (exocytosis or endocytosis). They also form integral part of axons and involved in axoplasmic transport of materials. Microtubules energise cilia and flagella for cell movement. Cytoplasmic microtubules are composed of tubulin (55 kD) and several accessory proteins called MAPs (microtubular-associated proteins) (300 kD and 60 kD).

**Intermediate Filaments**

Integrity of the cell is maintained by structural proteins, belonging to the microfilament intermediate class. The size of these filaments is midway between microtubules and microfilaments. They are structurally more stable and do not

**Fig. 52.8.** Cataract. Lens becomes opaque
undergo chemical or physical conformational changes. Hence, they act more as a structural protein for the integrity of cytoskeleton. The groups of intermediate filaments include keratin, desmin, vimentin, neurofilaments and glial filaments.

LENS PROTEINS
India has the maximum number of blind persons of the world. Cataracts and opacities of cornea are the cause for 70% of blindness. The eyes of older people and diabetics are prone to cataract formation. Being avascular, lens relies on the aqueous humor for the provision of oxygen and essential metabolites. Uppermost part of the lens consists of a monolayer of epithelial cells, which divides and differentiates to form the long fiber cells, that make up the lens. These normal lens cells (but not the old cells) possess the usual protein synthesizing machinery. The proteolytic activity of the lens is quite low and is due to the presence of endogenous protease inhibitors. Lens tissue has a very active HMP shunt pathway, and has the maximum concentration of NADPH. Lens also contains high quantity of ascorbic acid. They scavenge the free radicals and maintain the transparency of lens.

Crystallins
Major lens proteins are alpha, beta and gamma crystallins. Small quantities of delta and epsilon varieties are also described. They undergo no replacement throughout the life of the individual. There is no turnover of these proteins. The proteins at the center of the lens are as old as the individual. The orderly arrangements of the molecules make the lens proteins transparent. Alpha crystallin is present not only in lens, but is seen in almost all cells of the body.

Cataracts
When lens proteins change in their three dimensional structure, lens becomes opaque (Fig. 52.8). This is similar to the clear albumin becoming white and opaque when heated and denatured. In diabetes mellitus, when the blood glucose level is increased, lysine residues of these proteins are glycated. This leads to increased susceptibility for sulfhydryl oxidation and consequent aggregation of the proteins, resulting in opalescence and cataract. Protein aggregates with molecular weight more than 50 million will produce scattering of light.

In lens, the enzyme aldose reductase reduces monosaccharides to corresponding sugar alcohols; glucose to sorbitol and galactose to galactitol. These polyols do not readily cross cell membranes and hence accumulate; causing osmotic swelling, and consequent disruption of cell architecture. Thus, diabetes mellitus (increased glucose in blood) and galactosemia (high galactose level) cause cataract. Drugs that inhibit aldose reductase are shown to retard cataract formation in diabetic rats.

PRIONS
The central dogma in molecular biology postulated by Watson and Crick in 1953 was that genetic information passes from DNA to RNA and then to protein. In general, this rule still holds good. In 1970, Temin and Baltimore showed that DNA could be synthesized from RNA by reverse transcriptase. This has partly shattered the central dogma. But could proteins act as an information molecule? Could proteins replicate themselves? This question was considered to be heretical till a few years ago, but no longer so. There are a few diseases characterized by very long incubation period of many years. These “slow disease agents” were originally thought to be “unconventional viruses”, but now they are proved as prion proteins.

Prion Proteins : Abnormal Tertiary Structure
“Prions” is the acronym for “proteinaceous infective particles”. Stanley Prusiner has described prion proteins (PrP) in 1982, who was awarded Nobel Prize in 1997. PrP is a normal protein of 253 amino acids, found in leukocytes and nerve cells. The matured prion protein (PrP) has 210 amino acids. It exists as a sialoglycoprotein, anchored on the cell surface. PrP molecules can undergo a change in structural conformation. The altered molecule is resistant to heat and proteolytic enzymes. The abnormal protein is called PrPsc; “sc” stands for scrapie, the disease in which it was first isolated. Thus, prions are proteins with correct primary
structure, but with abnormal tertiary structure. The PrP is in alpha helical form; but PrPsc is in beta pleated sheets (Fig. 52.9).

Protein folding occurs in a stepwise process. As the polypeptide is being synthesized by the ribosome, the initial segment of protein starts to fold. That in turn favors only certain folding in the next part of the protein. By this time, hydrophobic regions aggregate into interior of the protein molecule. Chaperons (Chapter 41) also help in the formation of correct folding of proteins. This process is orderly. Minor alterations in the process may alter the tertiary structure.

Abnormal Proteins can be infectious
A normal gene makes the normal PrP protein. Disease is produced when the gene is mutated or if an abnormal PrPsc is injected or ingested. The "Seeding Model" explains that the infectious prion induces the nearby normal protein molecules to unfold to abnormal form. It is similar to the conversion of the good "Dr.Jekyll" to the criminal "Mr. Hyde" (same person with two personalities, described in the famous novel). These abnormal proteins now convert further normal proteins into abnormal varieties, producing a "chain reaction" that generates new infectious materials.

Pathogenesis of Prion Diseases
The lysosomal enzymes could break down the normal PrP; but PrPsc cannot be digested. Hence, the prions are accumulated inside the cells, and eventually the cell dies. One part of prion protein can cause apoptosis (programmed cell death), which also leads to loss of cells. As a group, they are also called transmissible spongiform encephalopathies (TSF), because the brain becomes riddled with small holes like a sponge. Neurons degenerate, protein deposits may accumulate as plaques and glial cells grow larger. Clinically, rapidly progressive dementia sets in with neurological defects and ataxia. All the prion diseases are slowly progressive, but eventually become fatal.

Human Prion Diseases
Prion diseases in human beings are Kuru, Creutzfeld-Jakob disease (CJD), Gerstmann-Straussler-Scheinker disease (GSSD) (familial CJD) and fatal familial insomnia (FFI). Cerebral cortex becomes sponge like in CJD. Thalamus is affected in FFI. In Kuru, cerebellum is affected. It is seen in Fore aborigines in Papua New Guinea. The term "Kuru" means "laughing death" in the tribal language. Baruch Blumberg showed that the disease was transmitted by ritual cannibalism (eating of brain of dead person); Carleton Gajdusek isolated the "unconventional virus" from the affected individuals; both of them were awarded Nobel Prize in 1976.

Prion Diseases in Animals
Classical example of the "slow disease" is scrapie disease in sheep. It is characterized by constant scratching; hence the name. The disease is manifested only about 10 years after the entry of the agent. In Bovine spongiform encephalopathy (BSE) (mad cow disease) the brainstem is affected. It has resulted in economic disaster in Great Britain in 1996. Cattle feed containing infected meat from sheep suffering from Scrapie caused the entry of prions into millions of cows. Thus, it is obvious that prions had crossed the species barrier from sheep to cattle. Could it cross to human beings? Hundreds of thousands of infected animals have been eaten by Europeans. Already there are reports that some of them did get CJD; this is called new variant of CJD (nvCJD).

Alzheimer's Disease (AD)
It was first reported by Aloysius Alzheimer in 1906. It is not proved to be a prion disease. But it is known that the disease is due to alteration of a normal protein. About 5-10% of people above 60 years are affected by AD. As the number of aged persons is increasing, the condition is becoming a major health problem in India. It is characterized by slow progression of memory loss, confusion, dementia, hallucinations, personality changes, and finally patient enters into a vegetative state with no comprehension of the outside world. Shakespeare's King Lear; who is losing his memory and becoming disoriented is a well-known example. Patient may require round the clock care and protection. The abnormal behavior of patient affects the whole family and is a serious psycho-social problem. Death occurs about 10 years after the first onset of the symptoms. There is no definite treatment now available. The drug that antagonises N-methyl-aspartate receptors is available, which will slow down the progression of the disease. Omega-3 fatty acids may be helpful in prevention of the disease.

Molecular Defects in AD
The pathological hallmarks of AD are neurofibril tangles in CNS, senile neuritic plaques and cerebral amylloid deposition. Inflammation within the brain plays a role in the development of Alzheimer's disease; and long-term use of anti-inflammatory drug was found to reduce the incidence of this disease. The neurofibrillary tangles are paired helical filaments made up of Tau protein. Normal Tau is soluble and catabolized easily; but abnormal Tau is insoluble, cannot be degraded by tissue cathepsins and are deposited around neurons. Tau is required for stabilizing axonal microtubules, the communication channels in nerve fibers. As insoluble Tau is deposited, there is loss of microtubules in AD. The synthesis of acetylcholine is also reduced, leading to memory loss. Diabetes mellitus and hypertension are associated risk factors for AD.

Amyloid Precursor Protein (APP)
Neuritic plaques are composed of beta-APP; a 40 amino acid fragment derived from APP (Amyloid precursor protein). APP is a normal constituent of human serum. It is produced by a gene located in the long arm of chromosome No. 21. Mutation in APP gene leads to a valine to isoleucine substitution. Then APP cannot be cleaved at appropriate position. A wrong cleavage produces beta-APP, which is precipitated around neurons as beta-amylloid. It is also known that aluminum can change the alpha helices of APP into...
beta-pleated sheets; then also APP becomes insoluble. This is similar to prion action. Aluminium toxicity causes AD-like disease.

**Alpha secretases** are a family of proteolytic enzymes that cleave amyloid precursor protein (APP) in its transmembrane region. Action of beta and gamma secretases on the amyloid precursor protein can result in the formation of a toxic conformation, called alpha-beta peptide. Alpha secretases are members of the ADAM (a disintegrin and metalloproteinase domain) family, which are expressed on the surfaces of cells and are used to anchor cells on the cell membrane. Upon cleavage by alpha secretases, APP releases a fragment known as APPs-alpha into the extracellular environment. The secretase complex is a prime target for pharmacological intervention in Alzheimer’s disease and so far drug discovery efforts have yielded a large variety of potent and rather specific inhibitors of this enzymatic activity. However, as gamma-secretase is able to cleave a wide variety of physiological important substrates, the real challenge is to develop substrate-specific compounds.

The **amyloid precursor protein** (beta PP) is cleaved by beta and gamma secretases to form amyloid beta protein (AbP) with 40-42 amino acids. The AbP fibrils are proved to be neurotoxic by studies conducted on mice. Early onset of Alzheimer’s have been seen in patients with Down’s and those with mutations in Beta PP. The gene encoding Beta PP is located on Chromosome 21 and in trisomy 21 the rate of production of beta PP and therefore AbP is increased. The toxic effects of neurofibrils include oxidative injury, changes in intracellular calcium homeostasis and cytoskeletal reorganization. Transmembrane proteins **presenilin1** and presenin 2 gene mutations have also been found to be responsible for excessive production of AbP.

27-hydroxycholesterol (27-OHC) may regulate a number of key enzymes within the brain. It regulates the generation of beta-amyloid peptides. 27-OHC is able to suppress expression of cytoskeleton-associated protein (Arc), a protein important in memory consolidation which is reduced in patients with Alzheimer’s disease (AD).

**Familial AD and Apo-E4 gene**
About 30% cases have genetic background; and these are called familial AD. Genes identified with AD are that coding for APP, presenilin-1 (chromosome 14), presenilin-2 (chromosome 1) or AD3 (chromosome 14) or AD4 (chromosome 1). Another major susceptibility gene for AD is the **Apo-E4** (apolipoprotein E4) gene situated in chromosome number 19. The presence of Apo-E4 gene is the major risk factor for AD. **Apo-E2** gene reduces the risk of AD. Apo-E2 acts as chaperone for the production of Tau. But apo-E4 binds with Tau to form tangles. Apo E gene is polymorphic and located on gene 19. There are three alleles of this gene with 6 possible combinations. Of these, the genotype acquisition of two alpha epsilon-4 allele increases the risk for Alzheimer’s disease about 8 fold. Each copy of the gene is increasing the risk and shifting the age of onset. Other genes on chromosome 12, 14 and 21 are implicated in the rare early-onset type of the disease. Abnormal forms of gene S182 located on chromosome 14 are responsible for early-onset familial Alzheimer’s disease.

**Parkinsonism**
Parkinsonism is a degenerative disease, affecting the muscular co-ordination. Two new genes associated with Parkinson’s disease have been reported. The first, called alpha-synuclein, is mutated in Parkinson’s disease. The second, codes for a protein called **parkin**, which is associated with a juvenile form of Parkinson’s disease. In most of the Parkinson’s diseases, an inclusion body, known as a **Lewy** body, is seen in many regions of the brain. The Lewy body is associated with neuronal degeneration and is also seen in Alzheimer’s disease. Alpha-synuclein is also found in Lewy bodies.

**Protein Misfolding Diseases**
Most proteins in the body maintain their natural configuration or if that is partially lost are renatured by the action of molecular chaperones. If not successful, they will be degraded. However, about 18 different diseases, most of them fatal, are associated with extracellular deposition of normally soluble proteins which become insoluble as amyloid deposits. These include Alzheimer’s disease, Transmissible spongiform encephalopathies and other forms of familial amyloidosis. All these diseases are due to misfolding of proteins leading to a toxic conformation. A common feature in the altered conformation of the protein is the change from alpha helical to beta sheet structure which makes the proteins and aggregates resistant to normal proteolysis. The cause may be mutations, defects in chaperones or presence of inappropriate proteins.

Fibrillogenesis is initiated by the association of beta domains of two or more unfolded or misfolded amyloidogenic proteins to form a more extensive beta sheet. More protein molecules are recruited by the toxic conformer to form plaques.

Misfolded proteins undergo endoplasmic reticulum associated degradation. Disorders due to defective intracellular membrane transport include Chediak-Higashi syndrome, combined deficiency of factors V and VIII, Hermansky-Pudlak syndrome, I-cell disease, oculo-cerebro-renal syndrome etc.

**Tau Protein**
Normal function of Tau protein is to stabilize the microtubules in neurons by enhancing polymerization of tubulin. Taupathies result from hyperphosphorylation of tau proteins leading to formation of fibrillar polymers. There is enhanced activity of protein kinases and diminished activity of protein phosphatases.

**BIOCHEMISTRY OF AGING**
Aging is a natural phenomenon. As the average life-span is increasing in developing countries, the percentage of aged persons in the population is also increasing. In India, 7% of the population are above 60 years. The medical branch dealing with age-related diseases, is called Geriatrics or Gerontology. All the physiological processes decline as age advances. However, differences are observed in individuals, with regard to the disease progression, or how much physical and mental functions are deteriorated. These may be due to differences in lifestyle, diet, diseases and genetics. Onset of ageing is earlier in persons with hyperglycemia, hyperlipidemia and hypertension. Obesity and lack of exercise are other factors which hasten the aging process. Numerous theories have
been proposed to explain the causes of aging. The simplest theory is that aging is governed by an organism’s genetic inheritance or “Genetic clock”. Organisms may have “aging genes” that control the rate of aging and thus life-span.

1. Cellular theories of aging
Hayflick found that cultured human fibroblasts double only a limited number of times before they deteriorate, become senescent (aged), lose their capacity to divide and finally die. The number of cell divisions of cultured cell is roughly related to (a) the age of the cell donors and (b) the longevity of the species. For example, fibroblasts from the human embryos, when sustained in tissue culture, divide about 50 times before they die. Those taken from person after birth divide only 20 to 30 times. Many theories have been proposed for explaining why cells become incapable of divisions.

a. **Mutation or “error” theory**: Most biologists of gerontology, believe that as a person grows older, his genetic material (DNA) gradually becomes impaired. This deterioration may in some cases be caused by accumulated errors in the replication of DNA. Thus, mutation may cause aging.

b. **“Error catastrophe” theory**: According to this theory accumulation of errors in the amino acid sequence in proteins, specially errors that affect the specificity of enzymes needed for protein synthesis, will result in further mistakes in protein synthesis and consequently will lead to cell deterioration and death. These errors may not be the result of blind chance but may be purposefully programmed by the “aging genes”.

c. **Free radical reaction theory**: It is proposed that certain free radicals generate oxidative reactions which can lead to the deterioration of lipids, collagen elastin and other body substance and may cause aging (Chapter 20).

2. Pacemaker theories of aging
Ageing is caused in part by progressive breakdown in the immunological system. At present, evidence strongly indicates that the age-related decline in the immunological functions. This is mainly due to the decrease in activity of the T cells. The body can also produce antibodies called **auto-antibodies** that attack not only foreign substances but also to the natural proteins of the body. These auto-antibodies are speculated to cause age-associated diseases such as rheumatoid arthritis, systemic lupus erythematosus, etc. As age advances, immunological system becomes less able to distinguish “self” from “non-self” and as a result, proceeds to destroy normal and desirable proteins of the body.

3. Chalones
In normal tissues of the full-grown mammals an equilibrium state is reached between mitosis and cell death. Such **inhibition of cell division** is apparently the result of products of the tissues themselves. These tissue-specific inhibitors of mitosis are collectively called **chalones**. Each tissue produces 2 types of chalones, one of low molecular weight (about 1000 to 3000) and another of high molecular weight (about 30,000 to 50,000). When cells in tissue culture are freed of chalones by washing they resume mitosis and proliferation. Chalones presumably attach to specific receptor sites on cell membranes and exert their inhibitory effects. In summary, the major contributory factors of aging process are: (a) Reactive oxygen species; (b) Cellular senescence; (c) Apoptosis or programmed cell death; (d) Somatic mutations in cellular and mitochondrial DNA.

4. Telomerase
Another molecular cause for senescence is the declining activity of **telomerase** (Fig. 40.19). Telomerases are essential for stabilizing the chromosomes. As age of the cell progresses, telomerase activity progressively decreases. So there is sequential shortening of the length of the DNA at each division. This leads to eventual cell death. Malignancy leads to continuous expression of telomerase, with consequent immortality of cancer cells.

5. Mutations in mitochondrial DNA
Mitochondrial DNA is more exposed and susceptible to damage by free radicals (reactive oxygen species). Such damages when accumulated, lead to reduction of oxidative phosphorylation. The exposure to oxidative stress leads to irreparable damage, and final destruction of the cell.

6. Heat shock proteins (HSP)
They are products of highly conserved genes. HSPs protect the cell against a variety of stresses such as, heat, heavy metals, drugs and toxins. The HSPs will mediate the disposal of damaged proteins and guide towards the correct folding into exact three-dimensional structure (Chapter 41). The HSP response is reduced in senescent cells and in older individuals.
CHAPTER 53

Applications of Isotopes in Medicine

CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Isotopes
2. Radioactive decay and half life
3. Units of radioactivity
4. Research applications
5. Diagnostic applications
6. Treatment applications
7. Biological effects of radiation

INTRODUCTION
Lord Ernest Rutherford (Nobel prize, 1908) put forward the nuclear theory of atom. Accordingly, the atoms are composed of a central dense positively charged nucleus, around which negatively charged electrons revolve. Subatomic stable particles are proton, neutron and electron.

Proton carries one positive charge (+4.8 x 10^{-10} esu) (esu = electrostatic unit). Proton is generally abbreviated as P^+. The nucleus of hydrogen contains only one proton. Therefore ionized hydrogen is otherwise called as proton. Although protons are said to be stable in the ordinary sense, in the cosmological sense, protons also decay. The half-life of proton is $10^{15}$ years. The body of a person contains about $10^{40}$ protons.

Neutron is abbreviated as ‘n’. It carries no net charge. It has the same mass as that of proton. Protons and neutrons together constitute the nucleus of atoms. Therefore, the atomic weight of an element will correspond to the total number of protons and neutrons present in the nucleus.

Electron is generally abbreviated as $e^-$. It is negatively charged ($-4.8 \times 10^{-10}$ esu) and revolves around the nucleus. The mass of an electron is only 1/2000 of a proton. Electrons are the fundamental units of electricity. An electric current is produced by a stream of electrons.

Valency: Electrons are taking part in all chemical reactions. The electrons revolve around the nucleus at different energy levels or in shells. Sodium has the atomic number 11. It contains 11 electrons, distributed as 2 in K shell, 8 in L shell and the remaining 1 in M shell. The natural tendency for an atom is to completely fill up the shells with electrons. Hence sodium atom tends to lose the electron from the outermost shell, and exist as Na^+ ion. Similarly chloride contains 17 electrons, 2 in K, 8 in L and 7 in M shells. If one more electron is accepted by the atom, the outermost shell will be completed. Hence the tendency for chlorine to gain one electron to become ionized. Thus sodium can donate one electron and chlorine can receive it. This is the basis of the chemical reaction between sodium and chloride. In the above example, the valency of both sodium and chlorine is said to be one, because they exchange one electron.

ISOTOPES
Isotopes are the elements having the same atomic number (protons) but different mass number (varying number of neutrons). The Greek word "iso" means equal and "tope" means place; that is, isotopes occupy the same place in the periodic table. The accepted convention is that mass number is written on the upper left side of the symbol letters to denote the particular isotope. Atomic number may be shown on the left lower corner of the symbol.

For example, $^1$H is normal hydrogen with 1 proton. It is present 99.985% of hydrogen ions in nature. $^2$H is heavy hydrogen or Deuterium. It has 1p + 1n. It is present only 0.015% in nature. $^3$H is Tritium with 1p + 2n. It is not present in nature, but
may be produced artificially. These three isotopes of hydrogen will react similarly in chemical reactions, because all of them contain only one electron.

To take another example, $^{16}$O is normal oxygen, $^{17}$O is unstable and $^{18}$O is stable isotope.

**Isobars** are atoms having same mass number, but are having different atomic numbers, e.g. $^{14}$C and $^{14}$N.

**Atomic Number and Atomic Weight**

The number of protons (or electrons) in an atom will determine the **mass number** or its place in the periodic table. The presence of neutrons will add on the mass of the atom. The **atomic weight** or mass number is equal to the number of protons plus neutrons in the atom.

The atomic weight of chlorine is actually 35.457. When calculated from the theoretical "$p + n$", the value should be the round figure of 35. This difference is because, in nature, chloride is made up of atoms having mass numbers of 35 and 37, in approximately 3:1 ratio.

**RADIOACTIVITY**

Isotopes may be stable or unstable (radioactive), and the latter may be naturally occurring or artificially made. In the above example, Deuterium is stable, which will not alter its nuclear composition during passage of time. But tritium is unstable and will transform by nuclear decay. The spontaneous degradation of nucleus and transmutation of one element to another with consequent emission of rays or particles is known as radioactivity. Chemical reactions are based on the activity of electrons, while radioactivity is due to subuclear components. Elements capable of undergoing radioactive decay are called **radionucleides**.

Antoine Becquerel was the pioneer in demonstrating spontaneous radioactivity (Nobel prize, 1903). Marie Curie and Pierre Curie were awarded Nobel prize in 1903 in physics, for their study on radiation phenomena. Marie Curie was awarded the Nobel prize again in 1911, but this time in chemistry, for the isolation of radium and polonium. In 1935, Nobel prize was awarded to Frederic Joliot (son-in-law of Madam Curie) and Irene Joliot (daughter of Curie) for artificial production of radioactive phosphorus from aluminium.

**Radioactive Decay**

1. **Alpha Decay**

When the alpha particle $(2p + 2n)$ is released, the element changes, the atomic number is reduced by 2 and mass number is lowered by 4. For example,

$$^{226}\text{Radium} \rightarrow ^{222}\text{Radon} + ^{4}\text{He ( }\alpha\text{ particle)}$$

The nucleus of Radium, being unstable, emits 2 protons and 2 neutrons (one helium nucleus) to become Radon-222. The alpha particles will carry 2 positive charges and produce maximum ionization in their path. Thus they are most damaging to tissues. Alpha particles emitted have a high mass and therefore a high momentum. They do not travel far and can be stopped by a few layers of paper. However they collide with other molecules and cause a lot of damage, hence considered to be most hazardous. The alpha radiations are not useful in clinical medicine. In fact, radium needles are covered so that alpha particles are absorbed, before applying to tissues. If not, the radiation in the vicinity of the needle will be hazardously high. The penetration power being negligible, the alpha radiation is stopped even by a few sheets of paper (see Table 53.1).

2. **Beta Radiation**

When a neutron is split, one proton, one electron (beta particle) and one neutrino are generated. The element is changed to one having a higher number in periodic table.

</tbody>
</table>
One neutron from carbon is changed to a proton. Therefore mass remains the same, but the element is changed with one number more in atomic number. The electrons thus emitted become the beta rays. So they are negatively charged. Since their mass is negligible, they can penetrate more distance. But they can be absorbed by metal sheets. The interaction with matter is less. Tritium ($^3$H) gets converted to helium on losing a beta particle. These beta particles have low velocity and tritium is said to be a soft beta emitter. $^{32}$P on the other hand has more kinetic energy is a hard beta emitter.

3. Gamma Radiation

While alpha and beta radiations are particles, gamma radiation is in the form of electromagnetic waves. Gamma ray has no mass and no charge, and therefore penetration power is maximum. It is now widely used for treatment of cancer cases. X-rays and gamma rays are similar electromagnetic waves (Table 53.1). But the former is less powerful (wavelength 100 Å to 1 Å), whereas gamma rays are more penetrating (wavelength 1Å to 1/1000 Å). The gamma radiation is produced by:

$$^{131}\text{Iodine} \rightarrow \text{Xenon (metastable)} \rightarrow \text{Xenon}$$

The first part of the nuclear reaction is similar to the beta radiation described previously. Thus the element with one more proton is produced. Here the resulting xenon is at a metastable state. It will release further energy in the form of gamma irradiation within a fraction of second to form the stable xenon. A comparison of different forms of radiation is given in Table 53.1.

### Half-life of Radioactivity

The radioactivity is halved within a fixed time. For example, if 100 mCi of $^{131}$I is kept, after 8 days the activity is seen to be 50 mCi. The half-life of $^{131}$I is 8 days (Fig. 53.1). The half-life is the time taken for a radioactive isotope to become half of its original activity. The rate of decay or the half-life is a constant for a particular isotope. A decay time of 7 half lives reduces the radioactivity to < 1% and that after 10 half lives is less than 0.1%. This is important in planning experiments and disposal of radioactive waste. The hazard of improper disposal of radioactive waste has caused exposure of innocent laymen in a recent incident in Delhi.

### Units of Radioactivity

Originally the units used for expressing the radioactivity were Curie and Rads. But the present system uses SI units, Becqueral and Gray.
1. **Curie (Ci)**
   One Curie, abbreviated as Ci, is equivalent to $3.7 \times 10^{10}$ disintegrations per second (dps) or 37 giga becquerals (gBq). This unit is used to measure the radioactivity of the source.

2. **Becqueral (Bq)**
   Becqueral (Bq) is defined as decay per second, (dps). 1 Bq = 1 dps. It is often expressed as kilobecquerals (kBq). Since bq is very small and Curie very large, their multiples and submultiples are used to express radioactivity. 1 micro Curie = 37 mega Bq. In clinical practice, it is not the radioactivity of the source, but the effect produced in the tissue that is more important. Therefore for therapeutic purposes, the following units are used.

3. **Rontgen (R)**
   It is the measurement of exposure dose. The radioactivity produces ionization in tissues. This is dependent on the quantity of radioactivity at the source, the distance from the source and the time of exposure. 1 R is the radiation which will give rise to $2 \times 10^9$ ion pairs/cc of air. One mCi source kept at a distance of 1 cm will produce 12.9 R/hour.

4. **Rad and Gray**
   Rad is the absorbed dose by tissue. 1 Rad = $1.5 \times 10^{12}$ ion pairs/g tissue. One Gray (Gy) = $10^7$ ergs/kg tissue = 100 rads.
   The biological effect of absorbed physical dose is expressed in Rads or Kilo Gray. Biological dose in SI units is expressed in Sievert (Sv).

5. **Rem**
   It is the Rontgen equivalent in man; where absorbed dose of rads is multiplied by the quality factor of the type of radiation. The biological effect of 1000 rads given as a single dose or in divided doses will be different. This biological effect of radiation is expressed in Rem.

**Applications of Radioactivity in Research**
Isotopes of an element will have identical chemical reactions. Hence when a radiolabelled compound is administered, these molecules are metabolized by the body similar to normal molecules. This is called **Tracer technique**. Almost all biochemical research will utilise such tracer methods. A few examples are given below.

i. Almost all the **pathways** described in earlier chapters were studied by using tracers. For example, $^{14}$C-labelled aceto acetic acid is shown to be incorporated into palmitic acid. Suppose labelled "A" is administered to an animal. After a few minutes, liver contains labelled "B" and after one hour, labelled "C" is seen in liver. Thus we can say that the pathway is A to B to C.

ii. The **turnover rate** of a substance in the body, that is, the rate of synthesis and breakdown could also be studied by tracer techniques. For example, if $^{131}$I-labelled immunoglobulin is injected, the quantity of the labelled molecules in the circulation will be proportional to the catabolism of the Ig. By such methods, it is shown that the half-life of IgG is 15 days, of albumin is about 21 days.

iii. $^{32}$P is useful to trace the nucleic acid synthesis **in vivo** and **in vitro**. It is therefore employed in genetic research. $^{3H}$-labelled thymidine is incorporated in the newly synthesized DNA and therefore used in assessing cell division kinetics. $^{51}$Cr is taken up by living cells and the label is liberated when the cell is lysed. Therefore it is used **in vitro** to quantitate the cell lysis by immunological or pathological mechanisms.

iv. The total body content of a particular substance (also designated as the "pool" of the substance) can be quantitated by the **isotope dilution technique**. To cite an example, 1 ml of $^{131}$I-labelled albumin is seen to have 1 million dps. This is injected intravenously to a man. The radioactivity will be uniformly mixed in the total blood volume. After 10-15 minutes, a blood sample is withdrawn. One ml of blood is shown to have a radioactivity with 200 dps. The volume injected and removed is the same 1 ml, but the original count is now diluted 5,000 times. Thus the intravascular space is 5,000 times more than the volume injected. Therefore the blood volume is 5,000 ml.

v. Similarly extracellular volume (intravascular + interstitial spaces) is determined by $^{24}$Na-labelled NaCl, and the total body water by means of $^3$H-labelled water. From such experiments it is shown that intracellular compartment is 40%, interstitial compartment is 16% and intravascular volume is 4% of the total body weight (Chapter 30).

vi. $^{14}$C is the most widely used isotope as a tracer in biochemical research, especially to study the pathways.

viii. Irradiation of food for packaging is carried out under the strict provisions of food safety procedures prescribed by FDA and radiation protection agencies. The radiations that can be used for irradiating food are specified. These include gamma rays from sealed units $^{60}$Cobalt and $^{137}$Caesium.

ix. **Carbon dating** technique is an important tool in paleobiology, the technique was developed by Willard Libby who was awarded Nobel prize in 1960.

**Applications of Radioactivity for Diagnosis**
The branch of medicine that deals with the diagnostic applications of radioactivity is referred to as **Nuclear Medicine**. A quick and accurate diagnosis can be made by radiomaging of organs like thyroid, liver,
bone etc. In some cases radioisotopes are used in the treatment of neoplasms in these organs. Diagnostic uses of radioactive tracers are using gamma ray emitters. These are short lived isotopes linked to chemical compounds that permit the observation of specific physiological processes. They may be given by injection, inhalation or orally. The earliest application of radioisotopes was in the 1950s, $^{131}$I for the diagnosis and treatment of thyroid disease

i. RBCs can be tagged with $^{51}$Cr. These cells when injected back will remain in circulation till the RBC is lysed. Therefore lifespan of RBC and intravascular hemolysis, if any, may be detected.

ii. Thyroid uptake studies by $^{131}$I are used to detect functional derangements of thyroid gland. About 15 mCi of $^{131}$I is given intravenously. After a few hours, the patient is monitored at the neck region by a movable gamma-ray counter, which will pick up the radiation emitted by the thyroid gland. The normal values are about 25% uptake by thyroid within 2 hours and about 50% uptake within 24 hrs. In hyperthyroidism there will be increased uptake and hypothyroidism shows the reverse effect.

iii. Thyroid scanning: Twenty four hours after administering the dose of $^{131}$I intravenously, the patient is placed under the scanner, which detects the radioactive emissions from the neck region. The actual distribution of radioactivity, with a picture of approximate size and shape of thyroid gland is produced. In hyperthyroidism, the increased radioactivity uptake is shown as heavily shaded areas. Sometimes the uptake of iodine is seen defective in certain circumscribed region of the gland, such a "silent nodule" is suggestive of cancer thyroid.

iv. Bone scanning: $^{90}$Sr (radioactive strontium) is employed. Osteoblastoma (cancer arising from bone forming cells) could be detected very early by this method, even before the appearance of radiological changes.

v. Kidney scanning is done by injecting $^{131}$I-labelled hippuran or $^{131}$I-labelled diodrast. Both are excreted by kidney within a few minutes after injection. Anatomical and physiological defects in the renal excretion could be easily identified.

vi. Technetium for blood flow studies: Blood flow of heart could be analysed by $^{99}$Tc (radioactive technetium). The half-life of $^{99}$Tc is less than 6 hrs. The method is sometimes called "nuclear stethoscope".

vii. Positron emission tomography (PET) scan is a more precise and sophisticated technique. Here the isotope is produced on the spot by a cyclotron. The emission of positrons and their combination with an electron resulting in the simultaneous emission of two gamma rays is detected by a PET camera. PET scan is widely used in Oncology with $^{18}$F as a tracer. Combination of PET and CT (PET-CT) improves the diagnostic accuracy. The abnormality may be either lesser uptake of the isotope by the organ (cold spot) or more uptake (hot spot). A series of images taken over a period of time will give specific patterns that indicate normal or malfunction of the organ concerned. An advantage over X-ray imaging is that both bone and soft tissues can be studied. The mean effective dose is 4.6 mSv per procedure (Sv is the abbreviation of sievert, the biological dose equivalent).

viii. Targetting: A more recent use of radio nucleides is by tagging them to monoclonal antibodies so that they can be specifically targeted to tissues.

ix. Radioimmuno Assays (RIA): Assays using $^{125}$I-labelled antigens are used to quantitate hormones, tumor markers and other biological substances present in blood in very small quantities. Details are given in Chapter 54. $^{125}$I with a half-life of about 60 days is used for tagging the proteins in vitro, as in the case of RIA. Another isotope of iodine, $^{131}$I with half-life of about 8 days is employed for in vivo purposes, such as thyroid scanning and for treatment purposes. The reduced half-life is advantageous in vivo to reduce the side effects of radioactivity to the patient.

Applications of Radioactivity in Treatment
Radioactivity is used for treatment of cancer. The radiations when absorbed by the tissues, produce ionization in the path. The nucleic acid in the cell is damaged, so that the next cell division is not possible. The radiotherapy is mainly affecting the cells in the division phase. Since cancer tissue contains more dividing cells than the normal tissue, cancer cells are preferentially affected by radiation. The radiotherapy may be classified as:

A. Unsealed Sources
These are radioactive substances kept in liquid form. The beta rays are the main effective radiation in these sources. For thyroid cancer and secondaries of thyroid cancer, $^{131}$I (dose 50–100 mCi) is administered. Similarly, $^{32}$P is used to treat polycythemia vera.

B. Sealed Sources
They utilise gamma irradiation. The source is applied on the cancer or sometimes implanted as a needle into the tissue.

Radium needles have the advantage of very long half-life. However during the decay, radioactive gas xenon is generated which may escape out if there is a leak in the covering. Because of this hazard, radium needles are now rarely used.

$^{137}$Cs (caesium) with a half-life of 30 years, is the preferred sealed source nowadays. Application of such sources directly on cancer tissue is called Brachytherapy. Intracavitary applications (for cancer of body of uterus, cancer of cervix uteri, cancer of vagina) and interstitial applications (buccal cancer, tongue cancer) are common.
C. Teletherapy

The term “tele” means distant (as in the case of telescope, telephone, etc.). Here the source of radiation is kept at a distance from the patient. Historically, teletherapy started with deep X-ray. X-ray was discovered by Wilhelm Rontgen in 1895 (Nobel prize, 1901). Due to its inefficiency, deep X-ray is no more used for cancer treatment. Instead, gamma rays from cobalt (60Co) or caesium (137Cs) are used for teletherapy. Here the energy equivalent is in the order of 2 MV (1 mega volt = 1 million volts). Therefore penetration power is more, and deep-seated cancers can be irradiated satisfactorily.

Linear Accelerator (LINAC): Caesium-based radiotherapy is no more used in western countries. In India also, gamma ray treatment is being slowly replaced by Linear Accelerator. Here electrons are accelerated to higher energy levels of 8-12 MV and directed into the cancer tissue. It has more penetrating power and accurate beam focussing capabilities. As there is no permanent radioactive source in the machine, the radiation hazards are minimal. LINAC is used for external beam radiation treatments for patients with cancer. The linear accelerator can also be used in stereotactic radiosurgery similar to that achieved using the gamma knife on targets within the brain; for Intensity-Modulated Radiation Therapy (IMRT) and Image Guided Radiation Therapy (IGRT). The linear accelerator uses microwave technology to accelerate electrons, then allows these electrons to collide with a heavy metal target. As a result of the collisions, high-energy X-rays are produced from the target. These high energy X-rays will be directed to the patient’s tumor and shaped as they exit the machine to conform to the shape of the patient’s tumor.

Radiosensitivity

The effectiveness of radiotherapy varies with different tumors. In general, lymphomas, Hodgkin’s disease and neuroblastoma are highly radiosensitive. Epithelioma, cancer of oral cavity, cancer cervix, cancer breast and cancer lung are moderately radiosensitive. Poorly radiosensitive tumors are osteosarcoma, and malignant melanoma.

Fractionation of Doses

Cancer cells are more actively dividing. In a cancer tissue, about 5-10% cells are in division, while in normal cells only less than 1% cells are dividing at particular time. Radiotherapy takes advantage of this difference between normal and cancer cells. Since radiotherapy affects only cells in division cycle (especially S phase), the radiation affects mainly the cancer cells. Recovery from radiation damage is quicker in normal cells than in cancer cells. The aim is to inflict maximum damage to cancer cells, while retaining the power of repair of the surrounding normal tissues.

However, radiation given in a single dose is not effective. Because dividing cells are only 5% in the cancer population and radiation kills only this fraction. Moreover, a single large dose will be lethal. Instead, small divided doses are given to the cancer tissue. Thus the fractionated dose is employed. By the next day more cells are entering in the S phase which are killed by the second dose. The total radiation dose is usually given in 15-20 fractions, administered within 25-35 days.

Cellular death after radiation depends on the number of cells in division. This produces a curious effect, each increment in dose kills a constant fraction of the cancer cells; but not a constant number of cells. An arbitrary example is shown in Table 53.3. While the first dose kills 1x10^9 cells, the 3rd dose can kill 1x10^7 cells only. However the percentage of cells killed is the same by each dose. In other words, the size of tumor is rapidly diminished in the initial phases of radiotherapy, but the last few cells are difficult to destroy. In fact, all the cancer cells cannot be eradicated by radiotherapy. The last few residual cells are annihilated by the immunological system.

**BIOLOGICAL EFFECTS OF RADIATION**

1. Direct Effects on Cancer Tissues

The radiation damages DNA molecules. No effects are visible immediately. But the damage is observed during the next mitosis. Since new DNA cannot be synthesized, cells die at the attempt of the next division. Chromosome breakage is often noticed. Radiation produces large quantities of free radicals in tissues. The catastrophic effects of free radicals on different biological compounds (including DNA) are described in Chapter 20.

2. Indirect Effects on Cancer Tissues

Damage to local blood supply cuts off the nutrition and causes local necrosis and cell death.

3. Effects of Radiation on Normal Tissues

In 1904, Madam Curie went for a lecture-demonstration class, keeping a few mg of impure radium
ore in her breast pocket. Within 1 hour, this caused severe dermatitis. That was the first indication of a health hazard by radioactivity. Madame Curie succumbed to radiation-induced leukemia in 1934.

3-A. Effects on Skin
Radiation will produce epilation, however hair may grow after 3 months. Sweat glands may be permanently damaged. There may be erythema and sometimes blisters. This is called acute radiodermatitis. Chronic radiodermatitis is seen after a few months of radiotherapy. There will be atrophy of skin, hypopigmentation, fibrosis, loss of elasticity, etc.

3-B. Effects on Mucous Membrane
The gastrointestinal mucosa is very sensitive to radiation. These include nausea, vomiting, diarrhea and in severe cases ulceration and bleeding. Late sequelae such as adhesions, fibrosis, stenosis and obstruction may appear many months after radiotherapy.

3-C. Effects on Blood Cells
Bone marrow and lymphoid tissues are highly radiosensitive because of the higher rate of cell division in these organs. Leukopenia and thrombocytopenia is an accepted side effect of radiotherapy. If WBC count is below 2,000/cu mm and platelet count is below 80,000/cu.mm, the therapy is temporarily stopped till recovery is effected.

3-D. Effects on Reproductive Organs
Gonads (ovary and testis) are highly radiosensitive. Complete sterility is effected at 1000 rads. Even low doses of radiation, too low to have any obvious effect on mitosis, can still affect the genes, so as to produce genetic alterations in the offspring. This is especially important when radiation is given in pelvic region.

3-E. Radiation Sickness
Dose above 700 rads given, as whole body irradiation, is usually fatal. Even 150 rads to the whole body will cause severe illness. In clinical practice, this is avoided by shielding the tissues in such a way that the beam is focussed to the cancer tissues only.

3-F. Carcinogenic Potential
During the period 1900-1910, people were working with X-rays without any precautions. This caused non-healing ulcers in many of them. During 1910s and 20s, lip cancer was common among painters of watch dial with radioactive stain. Gradually, along with the increasing knowledge on radiation hazard, stringent safeguard for radiation protection was introduced.

Acute Radiation Syndrome (ARS)
This may occur in accidents in nuclear reactors (e.g., Chernobyl accident) or the use of nuclear weapons in war (Hiroshima and Nagasaki). 15 to 25 rads will alter the blood count in exposed people, whereas the threshold for death in an individual is 150 rads. Other high dose effects are skin burns, hair loss, sterility and cataracts. Skin burns result from erythema, desquamation and blisters. Hair loss can occur after 500 rads. Cataracts (200 rads) are produced by neutrons because of the high water content in the lens.

Radiation Protection
There is always some amount of background radiation, of about 150 m Rem/year. Out of this, about 50% is from the cosmic rays, about 30% from terrestrial environment and 20% from internal environment (e.g. decay of $^{40}\text{K}$). Granite and brick walls will increase external background. At higher elevation, cosmic rays are more. At an altitude of 2000 m, (e.g., Gangtok, Sikkim state), the background irradiation is 20% more. In some coastal areas (e.g; Kerala state) natural deposits of radioactive thorium is seen, where background is 20-30% high. One diagnostic X-ray exposure may cause 75 milliRem.

Maximum Permissible Dose
The MPD of radiation for whole body among radiation workers, (doctors, technicians) is 5 mRem/year, and for general population is 0.5 mRem/year. Small doses (less than 10 cGy) of radiation may be good to living systems, while large doses are harmful; this is called Hormesis.

Radiation Monitoring and Precautions
Doctors, nurses, radiographers and research workers using the radioactive substances should wear a badge containing a piece of film. If radiation is reaching the film, it is blackened, and hence exposure could be detected. The following precautions will reduce the radiation hazards:
1. Keep the source farther away.
2. Shield the radioactive sources; cover them with lead bricks.
3. Handling is done by remote devices. Use lead-rubber gloves and aprons.
4. Radioactive materials are to be handled with speed. The shorter the time spent near the source, the lower the dose received.
CHAPTER AT A GLANCE
The reader will be able to answer questions on the following topics:
1. Electrophoresis
2. Adsorption chromatography
3. Partition chromatography
4. Ion exchange chromatography
5. Gel filtration chromatography
6. Radioimmunoassay (RIA)
7. Enzyme linked immunosorbent assay (ELISA)
8. The pH meter
9. Colorimeter
10. Spectrophotometer
11. Mass spectrometry
12. Fluorescent activated cell sorter

ELECTROPHORESIS
The term refers to the movement of charged particles through an electrolyte when subjected to an electric field. The positively charged particles (cations) move to cathode and negatively charged particles (anions) to anode. Since proteins exist as charged particles, this method is widely used for the separation of proteins in biological fluids. The technique was invented by Tiselius (Nobel Prize 1948).

1. Factors affecting electrophoresis
The rate of migration (separation of particles) during electrophoresis will depend on the following factors:
1. Net charge on the particles (pI of proteins)
2. Mass and shape of the particles.

2. Electrophoresis Apparatus
The electrophoresis system basically consists of the electrophoresis tank to hold the buffer and fitted with the electrodes, as well as a power pack to supply electricity at constant current and voltage (Fig. 54.1).

When the electrophoresis is carried out, the buffer is chosen in such a way so as to ensure effective separation of the mixture of proteins. e.g. serum proteins are separated at a pH of 8.6 using barbitone buffer. At this pH all serum proteins will have a net negative charge and will migrate towards the anode.

3. Support Medium for Electrophoresis
3-A. Filter Paper
If the support medium is a filter paper, the electrophoresis is carried out for 16–18 hours at a low voltage. This long time interval and diffusion of particles leading to blurring of margins are the disadvantages of paper.

3-B. Cellulose Acetate Membrane
Nowadays the preferred solid support media for horizontal electrophoresis is cellulose acetate membrane strips. They are expensive, but the process takes less than one hour and excellent separation without diffusion is achieved. Cellulose acetate strips are widely used for separation and identification of lipoproteins, isoenzymes and hemoglobins.

3-C. Agar or Agarose
These are less expensive than cellulose acetate. Both are heterogeneous polysaccharides. They are viscous liquids when hot but solidify to a gel on cooling. The gel is prepared in the buffer and spread over microscopic slides and allowed to cool. A small sample (few microliters) of serum or biological fluid

Fig. 54.1. Electrophoresis apparatus
is applied by cutting into the gel with a sharp edge. The electrophoretic run takes about 90 minutes. This technique is modified for immuno electrophoresis which is described later. The agar support is used to separate different types of protein mixtures as well as nucleic acids. Serum proteins are commonly studied by agar electrophoresis.

3-D. Polyacrylamide gel electrophoresis (PAGE)
It has a high molecular sieving effect and so separation is very efficient. In agar gel electrophoresis, serum components are separated into 5 fractions; while in PAGE serum will show more than 20 different bands. The amount of cross linking and thereby the pore size can be controlled.

Another common variant is the SDS-PAGE electrophoresis. Here proteins are boiled for 1-2 minutes with a denaturing agent, sodium dodecyl sulphate (SDS) (Fig. 54.2). The negative charges of SDS will cover the protein molecules, making them strongly negative. Then the separation of molecules will depend mainly on their molecular size. SDS-PAGE is therefore commonly used for molecular weight determination as well as for assessing the purity of proteins.

4. Visualization of Protein Bands
After the electrophoretic run is completed, the proteins are fixed to the solid support using a fixative such as acetone or methanol. Then it is stained by using dyes (Amido Schwartz, naphthalene black, Ponceau S or Coomassie Blue) and then destained by using dilute acetic acid. The electrophoretogram can be scanned using a densitometer and each band quantitated. In the densitometer, light is passed through the agar gel plate; the absorption of light will be proportional to the quantity of protein present on a band. Another method is that the stain may be eluted from the support and each fraction quantitated colorimetrically. The electrophoretic pattern of serum proteins on agar gel are shown in Figure 54.3. Abnormal patterns are shown in Figures 28.1 and 28.2.

5. Immuno electrophoresis
Here electrophoretic separation is followed by an antigen-antibody reaction. The electrophoresis is carried out first by applying the patient's serum into the wells cut out in the agar or agarose gel. The proteins are now separated. To visualize them, a specific antibody is placed in a trough cut into the gel and incubated. The precipitation arcs are formed where the antigen and antibody molecules are at 1:1 ratio (Fig. 54.4). Serum is fractionated into more than 40 bands. So it is much more sensitive and specific than ordinary electrophoresis.

6. High Voltage Electrophoresis (HVE)
Usually electrophoresis is carried out with an electric current of less than 250 volts. Since the separation of molecules depends on the strength of the current, recent trend is to utilize higher voltages (400 to 2000 volts). This is called high voltage electrophoresis (HVE). The advantage is that the result could be obtained within half an hour. It is now being widely used for separation of proteins, as well as nucleotides from biological fluids.

7. Capillary Electrophoresis (CE)
Here gel is taken in a capillary tube of small bore (50 to 100 microns) and having 100 to 200 cm in length. Nano liter range
of sample is injected into the tube. This is connected to buffer and a high voltage power supply of 25,000 volt is applied. Within a few minutes, components are separated. Amino acids, proteins, drugs, vitamins, carbohydrates and nucleotides could be separated by this method. Microchip electrophoresis applies the basic principle of capillary electrophoresis.

8. Isoelectric Focusing (IEF)
In a column, polyacrylamide matrix is filled with ampholytes (substances carrying both positive and negative charges). Biological fluid containing proteins or nucleotides are applied. Electricity is passed. The particles migrate, and settle in the matrix where pH matches the isoelectric pH (net charge is zero) of the particle.

9. Pulsed Field Gel Electrophoresis (PFGE)
In conventional gels, the current is applied in a single direction (from top to bottom). But in PFGE, the direction of the current is altered at regular intervals. Power is alternately applied to two different pairs of electrodes or electrode arrays. The electrical field is cycled between two directions. The frequency of field alterations separates large molecules like DNA with more than 50 kBp size to 400kBp using appropriate pore size gels.

10. Two dimensional electrophoresis
Used to study differences in protein content of cells in genetic disorders. The technique can also be used to study mutant DNA. Electrophoresis is done in the first direction based on the charge. Second dimension electrophoresis is based on molecular weight. The detection of the separated proteins may be done either by autoradiography or Coomassie Blue stain.

Ultracentrifugation
This technique was developed by Svedberg (Nobel prize, 1926). Large molecules can be sedimented at high centrifugal forces whereas small molecules cannot. The force in ultracentrifuges can go up to $10^5 \times g$. The centrifugation at such high speed is carried out in a vacuum to eliminate air friction. The rate of sedimentation is a function of the size and shape of the molecule and is a constant for a particular molecule. It also depends on the difference in the density of solute particles and the solvent. When solute particles are lighter than the solvent, they would float and vice versa. In density gradient centrifugation, the sample is layered over a linear sucrose gradient (5-20%) and centrifuged at a high speed. Sedimentation constant is expressed in Svedberg (S) units. Substances with different S units will separate from one another as separate bands. The sedimentation constants can be determined by using suitable standards. Ultracentrifugation is also used for preparative separation of biological molecules. See Chapter 12 for ultracentrifugation of lipoproteins.

CHROMATOGRAPHY
The term is derived from the Greek word chroma, meaning color. The method was first employed by Tswett, a botanist in 1903, for the separation of plant pigments using a column of alumina. Nowadays HPLC is used to separate almost all biological substances, including proteins, carbohydrates, lipids and nucleic acids.

1. Adsorption Chromatography
In this technique the separation is based on differences in adsorption at the surface of a solid stationary medium. The common adsorbing substances used are alumina, silicates or silica gel. These are packed into columns and the mixture of proteins to be separated is applied in a solvent on the top of the column. The components get adsorbed on the column of adsorbent with different affinity. The fractions slowly move down; the most weakly held fraction moves fastest; followed by others, according to the order of tightness in adsorption. The eluent from the column is collected as small equal fractions and the concentration of each is measured, in each fraction (Fig. 54.5A).

2. Partition Chromatography
This technique was developed by Martin and Synge in 1941 (Nobel prize, 1952). This includes different types depending on the phases between which the components are partitioned, e.g. solid-liquid, liquid-liquid, gas-liquid, etc. This is commonly used for the separation of mixtures of amino acids and peptides. There is a stationary phase which may be either solid or liquid over which a liquid or
gaseous mobile phase moves. By this process, the components of the mixture to be separated are partitioned between the two phases depending on the **partition co-efficient** (solubility) of the particular substances. The redistribution of the substances between the two phases results in separation of the components of the mixture.

### 2-A. Paper Chromatography

The **stationary phase** is water held on a solid support of filter paper (cellulose) (Fig. 54.5B). The **mobile phase** is a mixture of immiscible solvents which are mixtures of water, a nonpolar solvent and an acid or base, e.g. Butanol-acetic acid-water, Phenol-water-ammonia. Either ascending or descending type of chromatography can be done with the mobile phase being applied from the bottom (**ascending**) or at the top (**descending**). A few microliters of the mixture of compounds to be separated is applied as a small compact spot at one corner of the paper about 1 inch from the edges. In ascending chromatography, the paper is placed in a glass trough containing the solvent which ascends up the solid support medium. The components of the mixture to be separated are carried up with the solvent. The distance to which each compound moves depends on its partition coefficient.

### 2-B. Thin Layer Chromatography (TLC)

This is another version of liquid-liquid chromatography. A thin layer of silica gel (Kieselguhr) is spread on a glass plate; biological sample is applied as a small spot; the plate is placed in a trough containing the solvent. The stationary water phase is held on the silica gel and mobile phase of non-polar solvent moves up. In the case of paper chromatography, it takes 14-16 hours for separation of components to be separated. But in the case of TLC it takes only 2-4 hours. That is a distinct advantage for TLC. TLC can be performed as two dimensional; see Fig. 54.6A.

### 2-C. Visualization of Chromatography

After the chromatographic run is over, the paper has dried, it is sprayed with a location reagent. The components of the mixture would appear as discrete spots. Some common **location reagents** used are: Ninhydrin for amino acids and proteins, sulphuric acid for phospholipids; diphenylamine for sugars.

### 2-D. Importance of Rf Value

The spots may be identified by the Rf value of the unknown substance and comparing with those of pure standards. (Rf = ratio of fronts). The Rf value is the ratio of the distance travelled by the substance (solute) to the distance travelled by the solvent. The Rf value is a constant for a particular solvent system at a given temperature. Chromatogram of all the 20 amino acids is shown in Figure 54.6B.

### 2-E. Gas–Liquid Chromatography (GLC)

This is another type of partition chromatography where the stationary phase is a liquid and the mobile phase is gas. The stationary liquid phase is supported by a column of inert material such as silica in a long narrow column. The mixture of substances to be separated is made volatile at one end of the column and the vapors are swept over the column by an inert carrier gas like argon or nitrogen. The fractions emerging from the column are detected and quantitated by a detecting device. This is more suitable for compounds (e.g. lipids) which resist degradation at high temperature (Fig. 54.7).

### 3. Gel Filtration (Size Exclusion) Chromatography

It is also called molecular sieving. Hydrophilic cross linked gels like acrylamide (Sephacryl), agarose (Sepharose) and
dextran (Sephadex) are used for separation of molecules based on their size. Sephadex is widely used and the range of separation is based on pore size designated by the symbols G-10 to G-200. The gel is packed in a column. The gel particles are porous in nature. These pores will allow small molecules (e.g. insulin, mol. wt., 5700 D) enter into the gel. But larger molecules (e.g. immunoglobulin, mol. wt., 150,000 D) could not enter into pores of the gel and so are excluded. Suppose a mixture of insulin plus immunoglobulin is passed through the column. The small molecules can enter the gel particles, then come out, re-enter into another particle. Thus, insulin has to travel a long distance inside the gels. Small molecules are held back. But the large immunoglobulin molecules cannot enter the pores and sidetrack the gel particles; so they move in the column rapidly (Fig. 54.8). In short, larger molecules will come out first, while smaller molecules are retained in the column. The gel filtration technique is used for (a) separation of protein molecules; (b) purification of proteins; and (c) molecular weight determination.

4. High Pressure Liquid Chromatography (HPLC)

HPLC is now widely used for the separation of all types of compounds. Incompressible silica or alumina microbeads are used as the stationary phase. This allows high flow rates. The liquid phase passes through this column under high pressure (1000 times atmospheric pressure). The column may be packed with materials for adsorption, partition or ion exchange. The method is therefore based on the same principle as for those types already described, but separation is achieved with better resolution and high speed (within minutes) (Fig. 54.9). HPLC can resolve mixtures of lipids whose solubility differ only slightly. In reversed phase HPLC, hydrophobic polymers are used as stationary phase; this is generally used to separate peptides.

5. Ion Exchange Chromatography

In this method, the separation is based on electrostatic attraction between charged biological molecules to oppositely charged groups on the ion exchange resins (Fig. 54.10). These resins are cross linked polymers containing ionic groups as part of their structure. The polymer must be sufficiently cross linked to have negligible solubility, but porous enough for the ions to diffuse freely through it.

The resins are either cation exchange resins or anion exchange resins. The ionic groups in cation exchange resins are sulphonic and carboxylic groups, whereas anion exchange resins have a quaternary nitrogen (N⁺), e.g. Amberlite IRC-50 (weak cation); Dowex-3 (weak anion); and DEAE-Cellulose (strong anion). The separation is based on the ionic character of proteins and amino acids (iso-electric point). The cation exchange particles carry acid groups, e.g. COO⁻:Na⁺. When cations (C⁺) are passed through the column, Na⁺ in the resin
Textbook of Biochemistry; Section G: Advanced Biochemistry

is replaced by $C^+$; thus $C^+$ particles are adhered in the column, while negatively charged particles are eluted out easily (Fig. 54.10).

6. Affinity Chromatography
The technique is based on the high affinity of specific proteins for specific chemical groups. Thus co-enzymes can be used to purify enzymes. For example, NAD is used to purify dehydrogenases. By using antibodies, antigens could be easily separated (Fig. 54.11). Conversely, antibodies can be purified by passing through a column containing the antigen.

**RADIO IMMUNO ASSAY (RIA)**
The technique of RIA was developed by Rosalyn Yalow (Nobel prize, 1977). Insulin was the first substance thus quantitated by RIA. Nowadays, Hormones, growth factors, tumor markers, cytokines, bacterial antigens, and any other biological substances could be quantitated accurately by the RIA method. The specificity of antibody and the sensitivity of radioactivity are combined in this technique.

Suppose, blood level of thyroxin ($T_4$) is to be assayed. The $T_4$ hormone is the antigen (Ag) in this case. It is made to react with a specific antibody (Ab). A constant amount of isotope–labelled hormone, constant amount of antibody and variable quantities of unlabelled hormone are taken in different tubes (see Table 54.1 and Fig. 54.12).

In tube A, the labelled hormone molecules are combined with the antibody molecule; so there is no radioactivity in the supernatant. In B, equal quantity of unlabelled hormone is added, when labelled and unlabelled antigen molecules compete for the antibody. Thus half of radioactivity is in the supernatant and half in the precipitate. The **displacement of labelled antigen is proportional to the unlabelled antigen** in the system (Table 54.1).

A series of test tubes are taken, in which constant quantity of antibody, constant quantity of labelled antigen and different but known quantities of unlabelled antigen are added. After a few hours of incubation, a precipitating agent is added, when antigen–antibody complex, being high molecular
weight substance, is precipitated. The radioactivity in the precipitate is inversely related to the unlabelled antigen added. The values of the radioactivity in the precipitate (last column) are shown as a graph in Figure 54.13. In the same series of test tubes, patient’s serum may be added as the source for unlabelled hormone. The radioactivity in the precipitate is plotted in this graph at the Y-axis, when the corresponding value in the X-axis will give the actual quantity of hormone present in that sample. There is a competition between the unlabelled hormone (antigen) present in the biological specimens and the added labelled antigen to combine with the antibody (Fig. 54.12). The more the unlabelled antigen, less of the labelled antigen will combine with the antibody (Fig. 54.12 and Table 54.1). The antigen-antibody reaction is allowed to take place for a definite period of time. At the end of the incubation period, the tube will contain free and bound antigen (labelled or unlabelled), as shown in Box 54.1.

**Box. 54.1. Principle of Radio Immuno Assay**

\[
\text{Ag} + \text{Ag}^* + \text{Ab} \rightarrow [\text{Ag-Ab}] + [\text{Ag}^*\text{-Ab}] + \text{Ag} + \text{Ag}^*
\]

The bound and free forms are separated by protein precipitating agents such as polyethylene glycol or a second antibody. The radioactivity of the bound form in the precipitate is measured.

A series of standard tubes containing known but varying concentration of the pure antigen are taken along with the unknown biological specimen. The level of the hormone in the specimen can be obtained from a calibration curve prepared from the measured radioactivity of the known standards (Fig. 54.13).

**Solid phase RIA**

The antibody is fixed on the walls of the test tube, so that separation of bound and free radioactivity becomes practically easier.

**Immunoradiometric Assay (IRMA)**

The antibody (instead of the antigen) is tagged with radioactivity.

**Advantage of RIA**

By this method, microgram and picogram quantities of substances could be analysed. The radioisotope commonly used for labelling the antigen is \(^{125}\text{I}\) (radioactive iodine).

**Disadvantages of RIA**

Since radio-isotopes are used, there are stringent laws; and only approved laboratories could take up the assay. Half life of \(^{125}\text{I}\) isotope is about 60 days; iodinated antigen should be used within a few months. The shelf life of the reagent is short.
**Nonisotopic Immunoassays**

They have the **advantage** that there is no radiation hazard. So the test could be done in any clinical laboratory. The shelf life is also more. The ELISA technique is more simple and less time consuming than RIA. Instead of the radio label, an enzyme is tagged. The antibody is usually conjugated with the enzyme. The enzyme labels commonly used are alkaline phosphatase (ALP) and **horse radish peroxidase** (HRP).

**ELISA TEST**

ELISA is the abbreviation for **enzyme linked immuno sorbent assay**. The ELISA techniques are widely used not only for hormone measurements but also for detecting any other growth factors, tumor markers, bacterial or viral antigens, antibodies against microbes and any other antigens or antibodies in biological fluids. This test is commonly employed to detect antigens or antibodies present in very small quantities in tissues or blood.

**Antibody Detection by ELISA**

This is useful to detect small quantities of antibodies in the blood. A good example is the test for detection of HIV antibody. In patients with AIDS, the human immuno deficiency virus (HIV) produces specific antibody. To detect the HIV antibody, the following method is used.

Antigen from HIV is coated in the wells of a multiwell (microtiter) plate. Patient's serum is added, and incubated. If it contains the antibody, it is fixed. The wells are washed. This is to remove excess antibodies in serum.

Next a second antibody (antibody against human immunoglobulin) conjugated with HRP is added. Then color reagent, containing hydrogen peroxide and diamino benzidine (as described below, under antigen detection) is poured over. If a brown color develops, it means that the antibody was originally present in the patient's serum (Fig. 54.14). Here the **color developed is proportional to the antibody concentration.** Therefore from the color intensity, the concentration of the antibody can be calculated. HIV antibody is an example, any antibody could be detected by using the specific antigen.

**Antigen Detection by ELISA Method**

At first, specific antibody is fixed to the well of a microtiter plate. A good example is the assay of thyroid hormone, T\textsubscript{4}. The patient's serum is added in the well, and incubated for 30 minutes at 37°C.
Chapter 54: General Techniques for Separation, Purification and Quantitation

By this time, antigen (T4 in this example) present in the serum is fixed on the antibody. Excess antigen and other unwanted proteins are washed out.

Then, specific antibody (antibody against T4, tagged with enzyme (horse radish peroxidase) (HRP) is added. If the antigen is already fixed, the antibody-HRP-conjugate will be fixed in the well. Then a color reagent, containing hydrogen peroxide (H2O2) and diamino benzidine (DAB) are added. The reaction is as follows:

\[
\text{HRP} \rightarrow \text{H2O + Nascent Oxygen (O)} \\
\text{Diamino benzidine} \rightarrow \text{Oxidized DAB (Colorless)} \\
\text{(Brown color)}
\]

This is known as “sandwich” ELISA. Development of a brown color indicates that the antigen is originally present in the patient's serum. This is diagrammatically represented in Figures 54.15A and B). Color developed is proportional to the antigen in the serum. Therefore intensity of the color may be measured, from which the concentration of the antigen is calculated.

Other chromogens used in ELISA test are NBT (nitroblue tetrazolium; blue color; Fig. 54.16A) and NPP (nitrophenyl phosphate; yellow color).

### Immunofluorescence

Antibody tagged with fluorescein isothiocyanate is incubated with cells. Antibody fixes with cell surface antigens. Subpopulations of blood cells (e.g. helper T cells) are usually enumerated by this technique (54.16B).

### Immunocytochemistry

Histopathology sections may be layered with antibody tagged with Horse radish peroxidase, and then hydrogen peroxide and chromogen are added; color is thus produced. For example, a slide from colon cancer is reacted with specific antibody against an oncogene. Color is developed wherever the oncogene is present.

**Biotin-Avidin Complex**

Biotin will tightly bind with avidin (Chapter 34). Instead of enzyme directly fixed over the antibody; biotin is labelled on the first antibody. Then avidin-conjugated enzyme is added, and color reaction is done as before. The advantage here is that for each biotin fixed, 4 avidin molecules, and so 4 enzyme molecules are fixed. Thus intensity of color will be 4 times more intense. The sensitivity of the assay is thus increased many times.

**Enzyme Multiplied Immunoassay Technique (EMIT)**

In ELISA, antibody is tagged with enzyme; but in EMIT, antigen is labelled with enzyme. Serum containing the antigen and antibody are reacted. When antigen-antibody complex is formed, the active site of enzyme is not available for substrate binding. Such a system will eliminate the separation of antigen-antibody complex, or the washing procedure. This is a definite advantage of EMIT over RIA and ELISA techniques. So EMIT is more suitable for automated machines.

**COLORIMETER**

Colored solutions have the property of absorbing light of definite wavelengths. The amount of light absorbed or transmitted by a colored solution is in accordance with the Beer-Lambert law. As per the **Beer's law**, the intensity of the color is directly proportional to the concentration of the colored particles in the solution. The **Lambert's law** states that the amount of light absorbed by a colored solution depends on the length of the column or the depth of the liquid through which light passes. The **Beer-Lambert law** combines these two laws.

In the colorimeter, the length of the column through which the light passed is kept constant, by using test tubes or cuvettes of the same diameter for both test and standard, so that the only variable is the concentration.

The ratio of intensity of emergent light to intensity of incident light (E/i) is termed as **transmittance** (T). The absorbance is expressed as –log T. The **Optical Density** is calculated as –log T. The plot of the concentration versus transmittance is not

**Biotin-Avidin Complex**

Biotin will tightly bind with avidin (Chapter 34). Instead of enzyme directly fixed over the antibody; biotin is labelled on the first antibody. Then avidin-conjugated enzyme is added, and color reaction is done as before. The advantage here is that for each biotin fixed, 4 avidin molecules, and so 4 enzyme molecules are fixed. Thus intensity of color will be 4 times more intense. The sensitivity of the assay is thus increased many times.

**Enzyme Multiplied Immunoassay Technique (EMIT)**

In ELISA, antibody is tagged with enzyme; but in EMIT, antigen is labelled with enzyme. Serum containing the antigen and antibody are reacted. When antigen-antibody complex is formed, the active site of enzyme is not available for substrate binding. Such a system will eliminate the separation of antigen-antibody complex, or the washing procedure. This is a definite advantage of EMIT over RIA and ELISA techniques. So EMIT is more suitable for automated machines.

**COLORIMETER**

Colored solutions have the property of absorbing light of definite wavelengths. The amount of light absorbed or transmitted by a colored solution is in accordance with the Beer-Lambert law. As per the **Beer's law**, the intensity of the color is directly proportional to the concentration of the colored particles in the solution. The **Lambert's law** states that the amount of light absorbed by a colored solution depends on the length of the column or the depth of the liquid through which light passes. The **Beer-Lambert law** combines these two laws.

In the colorimeter, the length of the column through which the light passed is kept constant, by using test tubes or cuvettes of the same diameter for both test and standard, so that the only variable is the concentration.

The ratio of intensity of emergent light to intensity of incident light (E/i) is termed as **transmittance** (T). The absorbance is expressed as –log T. The **Optical Density** is calculated as –log T. The plot of the concentration versus transmittance is not
linear, but a graph of the concentration against absorbance (OD) is linear. Since it is in logarithmic scale, values too low or too high are not acceptable for accurate results (sensitive range is between 0.1 and 0.6). The method of estimation is arranged to give readings within this sensitive range.

Most of the clinical chemistry estimations are done by colorimetric methods. A colored derivative of the compound to be measured is prepared and its absorbance or OD is measured using a photoelectric colorimeter. This value is compared with that of a standard of known concentration. The basic components of a photoelectric colorimeter are:

1. Light source, usually a filament lamp
2. Filter, used for selecting the monochromatic light (mono = single; chrome = color). Filters will absorb light of unwanted wavelength and allow only monochromatic light to pass through. This light will have maximum absorbance when passed through a particular colored solution. The color of filter should be complementary to the color of the solution. Table 54.2 gives the color of filters to be used for the colors of solutions.
3. Sample holder, called "cuvette", made up of glass tubes
4. Detector (photocell)
5. Display as a digital meter (Fig. 54.17).

The monochromatic light is allowed to fall on the colored solution. The solution is taken in the cuvettes of fixed diameter to keep the path length common to the test as well as to the standard. The solution absorbs part of the light and the remaining transmitted light is allowed to fall on the photocells. The electrical impulse thus generated is measured and is suitably displayed.

In clinical laboratory, serum sample and reagents are mixed and incubated at 37°C for a fixed time, say 10 minutes, to develop the color optimally. After the incubation period, the OD is ascertained and the concentration of the substances is calculated. This is called end point analysis.

On the other hand, the serum and reagents are incubated, and readings are taken at 2 and 3 minutes exactly; and from the difference in OD between the two values, the concentration is calculated. This is the kinetic analysis. Here the optimum color is not developed; but is quicker and hence is often used in autoanalysers.

**Spectrophotometer**

A spectrophotometer has all the basic components of photoelectric colorimeter with more sophistication (Fig. 54.18). Wave lengths in the ultraviolet region are also utilized in the spectrophotometer. Light is separated into a continuous spectrum of wavelengths and passed through the solution. [In colorimeter, wavelengths of one color are grouped together]. Wavelength selection is achieved by diffraction gratings. The UV light is partially absorbed by the glass, and hence quartz cuvettes are used for the UV range.

The advantage of the spectrophotometer over the colorimeter, is that the former is 1000 times more sensitive. Therefore even minute quantities of the substance (very dilute solution) can be assessed in the spectrophotometer. To take an example, protein solutions with high concentration (mg/ml) may be measured by colorimeter. If the protein concentration is only microgram/dl, then colorimeter is ineffective, where spectrophotometer can be used.

However, spectrophotometer is 100 times more costly than an ordinary colorimeter. Further, the electrical power source operating the light must be carefully stabilized. Light emitted is proportional to the 8th power of the voltage. Therefore even minor fluctuation in the voltage will have an exaggerated effect.

The characteristic absorption maximum (in wavelength) of some important substances are; protein, peptide linkage...
(220 nm); protein, tryptophan units (280 nm); nucleic acids (260 nm); deoxy-hemoglobin (565 nm); bilirubin (450 nm); NADH (340 nm); FAD (450 nm); FADH2 (570 nm); porphyrin (400 nm).

**Luminiscence**
Chemiluminiscence, bioluminiscence and electro-luminescence are types of luminescences where the excitation caused by chemical, biological or electrical reaction respectively. In luminiscence, the light emission occurs from an excited singlet state and the light emitted when the electron returns to the ground state (higher energy to lower energy level). The excitation event is caused by a chemical reaction like oxidation of luminal, acridine esters or luciferin by an oxidant. Light is emitted from the excited product formed in the oxidation reaction. These reactions occur in presence of catalysts, commonly used ones are ALP, HRP, metal ions and complexes (copper and iron phthalocyanin complex).

**Bioluminescence** is a biological reaction, luciferase being a common biocatalyst used for increasing the efficiency of the reaction. CLIA (chemiluminiscence immunoassay) is a very sensitive method and has a sensitivity of femtograms detection. Labels used may be acridium ester, ALP labels (1,2 dioxane) and HRP labels (luminol). **Electroluminescence** is generated from stable precursors at the surface of an electrode; ruthenium tris chelate can be used to label haptens or large molecules like proteins.

**Optical Chemical Sensors**
An optical sensor is referred to as an optode. It is used in instruments measuring blood gases and electrolyte. Compared to conventional electrodes, optodes have certain advantages like miniaturization, long term stability and does not need a reference electrode. In the optical sensors, the light from the sensing side can be brought to light sources, filters and detectors that can monitor absorbance by reflectance, fluorescence or phosphorescence.

The optical sensors used for PO₂ measurements work on the principle of quenching of fluorescence or phosphorescence emitted at a particular wavelength by oxygen.

**Biosensors**
These are chemical sensors having an optical device or transducer and a biological recognition element. The concentration of the analyte is recognized by an enzyme based biosensor (catalytic reaction) or an affinity based sensor (binding specificity). When the recognition element interacts with the analyte, there is product formation or reactant consumption on the surface of the sensor. This change in property is converted by a transducer to an electrical signal and quantified.

Enzyme based biosensors are used in different analysers for quantification of glucose (PO₂ electrode), urea, creatinine etc where the enzyme is immobilized on the sensor. Affinity sensors have immobilized molecules with specific high affinity binding properties like binding proteins, antibodies, aptamers (DNA sensors) etc. In vivo miniaturized sensors are being developed for measurement of SaO₂, pH etc. Implantable subcutaneous glucose sensors are also being used to adjust the dose of insulin. Intravascular sensors that release nitric oxide have been developed to decrease the possibility of thrombosis.

**Flame Photometer**
This is an analytical instrument used for quantitative analysis of sodium, potassium, calcium and lithium in biological fluids like blood, serum and urine.

In a colorimeter the optical absorption property is employed, while in a flame photometer the property of emission spectroscopy is utilized. Sodium, potassium, calcium and lithium have the property of emitting a light of the characteristic wavelength of that particular element, when sprayed into a flame (incandescence).

The equipment consists of an atomiser, which draws sample solution; and a compressor which pumps air at high pressure. It is fed into a flame. The flame will be blue, if the sample contains only distilled water. When the serum sample is introduced, the flame acquires the color. The emitted light is focussed on to the photosensor. The electric charge given out by the photosensor is detected, amplified and displayed.

It has to be compared with a standard solution containing sodium/ potassium (Fig. 54.19).

**Ion Selective Electrodes**
Nowadays, more sensitive but costly equipment, using ion-selective electrodes are available to detect sodium, potassium, calcium and lithium. Glass electrode, made up of very thin glass membrane, allows ions to permeate through. The potential difference across the glass membrane of the electrode is quantitated by the instrument.

**The pH Meter**
The hydrogen ion concentration and pH are described in Chapter 33. pH = −log [H⁺]. pH is measured accurately by potentiometric methods. An electrode potential is generated across a selectively permeable membrane separating two different concentrations of an ion. A second electrode is required to act as the reference. The active electrode will be sensitive to the ion being measured; while the reference electrode will be insensitive to that ion.

The **Glass electrode** is made of a very thin glass membrane, which allows passage of hydrogen ions. Inside the bulb of the glass electrode, a solution of known hydrogen ion concentration is kept and a silver-silver chloride electrode connects the solution to the input part of the instrument. The reference electrode or calomel electrode (mercury with mercurous chloride) is filled with KCl solution. In the equipment, the test and the reference electrodes are made physically together for easy handling (Fig. 54.20). Glass electrodes require very delicate handling. When not in use, the electrodes must be kept immersed in distilled water.

The potential difference across the glass membrane (inside and outside) is calculated by Nernst (Nobel prize, 1920), the equation being

\[
\text{RT} / nF \times 2.3 \log \left( \frac{[H^+]_i}{[H^+]_o} \right)
\]

where R= gas constant; T= absolute temperature, n=valency, F= Faraday, [H⁺] = concentration of hydrogen ions inside the cell and [H⁺]₀ = concentration outside, that of the unknown solution.
AUTO ANALYSER
By means of this modern equipment, hundreds of blood samples could be analysed within a short time.

Continuous flow analysis
In these instruments, samples, reagents and diluents are pumped through different tubings. Samples are introduced in a sequential manner, through the network with air bubbles at regular intervals which mix the reagents with the sample. The continuous flow systems, despite being the forerunner, have now fallen out of favor due to the high cost for maintenance.

Automated photometric analysers
These are semi-automated analysers. Some of the steps involving pipetting of the sample, reagent mixing and incubation are manually done, while aspiration of the colored solution into the photometer as well as measurement, calculation and display or printing of the results are automatically done. The instrument is meant for parameter oriented analysis. It can analyse only one parameter at a time (e.g. urea), but many samples can be measured at a rapid rate.

Discrete analysers
These may be either batch analysers or selective multichannel analysers.

Batch analysers
Here all samples are analysed for one constituent only and analysis is parameter oriented. Once samples are loaded, all processes are performed automatically with little manual intervention.

Discrete selective analysers
They are the most sophisticated systems, that have the capability of analysing simultaneously 40 or even more parameters in a single sample. It is therefore called sample oriented. But at the same time, it offers the freedom to the operator to select any number of analyses on a sample.

Dry Chemistry Systems
Here all the reagents necessary for the reaction are embedded on a plastic matrix in their dry state, thus obviating the need to prepare reagent solutions. The reaction is initiated by the addition of the sample over the matrix and the color that is produced by the reaction is measured by reflectance spectrophotometry. Introduction of such system is bound to have a significant impact on the emergency practice of critical care medicine.

Fig. 54.20. pH meter
Fig. 54.21. Glucometer

Glucometers are working on this dry chemistry principle (Fig. 54.21). Glucometers are usually used by the diabetic patients for blood glucose analysis at their home.

MASS SPECTROMETRY (MS)
MS is very sensitive quantitative analytical technique used to measure a wide range of clinically relevant analytes. MS identifies molecules based on their mass or molecular size. MS measures the mass of a molecule or its fragments after ionization according to mass to charge ratios. Relative abundance of each ion is a function of its mass to charge ratio. When interfaced to HPLC or GLC, the MS functions as a powerful detector.

A sample is vaporized such that positive charge is produced on the molecule. Electrical field is applied, so that particles move. At the same time, a magnetic field is applied, so the cations are deflected at right angle to their original direction, and hit on the detector. For molecules of identical charge, the time required for the molecule to reach the detector is inversely proportional to the mass of the molecule (Fig. 54.22). Conventional MS identifies molecules of 4000 D or less. For higher molecular size materials, time-flight mass spectrometers are useful.

For analysis in MS, the sample has to be vaporized first. Small biological molecules could be vaporized by heating in a vacuum. But complex molecules such as proteins, nucleotides etc are destroyed by this procedure. So such molecules are vaporized by electrospray ionization (ESI). Here the molecules are dissolved in a volatile solvent, sprayed as a small jet stream into a capillary chamber, so that molecules are suspended in the gaseous phase, and are ionized.

Recently introduced method of dispersion of molecules in gas phase is the Matrix assisted laser desorption ionization (MALDI). In MALDI method, the sample is mixed with a light absorbing dye and a source of protons. This mixer is excited with a laser beam, causing the matter dispersed into the gas phase, so the molecules are not denatured.
Collision Induced Disintegration
Inside the MS, peptides can be broken into smaller units by collision with helium or argon atoms. The molecular size of these fragments could be analyzed. As the molecular weight of each amino acid is known, the amino acids in the fragments could be identified.

Tandem Mass Spectrometry (MS-MS)
Two mass spectrometers are arranged sequentially. The first MS separates big peptides, based on their mass. From this observation, a single peptide can be directed into the second MS (called parent ion or precursor ion). The parent ion enters the collision cell of the second MS. Here the ions collide with argon gas molecules and are broken into smaller ions. These daughter ions (product ions) are detected and quantified by their mass spectrum in the second instrument. The high selectivity of MS-MS is that the parent ion mass and daughter ion mass are used for characterization. If combined with chromatographic separation, the retention time also becomes a factor. The applications of MS-MS include identification and quantification of proteins, drug screening, pesticides and pollutants and screening of inborn errors of metabolism, especially organic acidurias.

Fluorescence Activated Cell Sorter (FACS)
The instrument is very widely used to separate lymphocyte subpopulations and stem cells. The cells are passed through a capillary nozzle one at a time (Fig. 54.23). As the cells flow down the stream of liquid, they are scanned by a laser. Some of the laser light is scattered by the cells and this is used to count the cells. This scattered light can also be used to measure the size of the cells. Subpopulation of cells can also be separated by the same procedure. Here, the cells are tagged with a specific antibody linked to a fluorescent dye. The antibody is bound to a protein that is uniquely expressed on that particular group of cells. (If two different antibodies are used, with two different colored fluorescence, two different groups of cells could be tagged in the same sample). The laser light excites the dye which emits a color of light that is detected by the light detector. An electrical charge is applied to the stream and the cells will get a charge. These charged cells are then deflected left or right by charged electrodes and into waiting sample tubes. Drops that contain cells with no fluorescence are sent into the waste tube. So, pure subpopulations of cells are collected in three different tubes.

Fig. 54.23. Fluorescent activated cell sorter
The reader will be able to answer questions on the following topics:

1. DNA hybridization techniques
2. Southern, Northern and Western blots
3. Animal cloning
4. Molecular cloning
5. Restriction fragment length polymorphism
6. Polymerase chain reaction (PCR)
7. Monoclonal antibodies
8. Single strand conformation polymorphism
9. Heteroduplex Analysis
10. Conformation sensitive gel electrophoresis
11. Protein truncation test (PTT)
12. Denaturing HPLC (DHPLC)
13. DNA sequencing
14. Bio-informatics
15. Nanotechnology

Molecular (DNA based) diagnostics is rapidly becoming a standard laboratory procedure for a large number of disorders. Many DNA based molecular techniques are being used in clinical practice. In addition to the diagnosis of a particular patient, molecular diagnostics can be used for diagnosis of index cases, prenatal diagnosis and screening. In many cases, the diagnosis is based on detecting mutations in genes involved, but in some cases it may be detecting changes in DNA copy number which leads to changes in gene expression. Still further, there may be changes at the transcription level (production of increased mRNA) which leads to increased protein synthesis by the corresponding gene. In this chapter, a brief review of major molecular techniques employed in clinical diagnosis is given.

HYBRIDIZATION AND BLOT TECHNIQUES

1. Probes
A probe is defined as a single stranded piece of DNA, labelled (either with radioisotope or with non-radioactive label), the nucleotide sequence of which is complementary to the target DNA. The DNA of the specific gene is used for the hybridization techniques. The DNA is nicked (a few breaks are made) and repaired. During this process, $^{32}$P-labelled dCTP is added. Therefore, the radioactivity...
is tagged into the gene. This is called Nick-translation. Nonradioactive probes are also available and fluorescent probes are easier to detect.

2. Southern Blot Technique
It is based on the specific base pairing properties of complementary nucleic acid strands. This technique is therefore based on DNA hybridization (Fig. 55.1). The blot technique was developed by EM Southern in 1975. This is used to detect a specific segment of DNA in the whole genome.

DNA is isolated from the tissue. It is then fragmented by restriction endonucleases. The cut pieces are electrophoresed on agarose gel. It is then treated with NaOH to denature the DNA, so that the pieces become single-stranded. This is then blotted (adsorbed) over to a nitrocellulose membrane. The single-stranded DNA is adsorbed in the nitrocellulose membrane. An exact replica of the pattern in the gel is reproduced on the membrane (Fig. 55.2). The DNA is then fixed on the membrane by baking at 80°C. There will be many DNA fragments on the membrane, but only one or two pieces contain the target DNA. The radio active DNA probe is placed over the membrane. If the target genes are present in the host DNA, the probe will detect the complementary nucleotide sequence in the host DNA (see Figures 55.2 to 55.4A). So the probe is hybridized to the particular pieces of host DNA. The membrane is then thoroughly washed to remove excess probes. An X-ray plate is placed over the membrane in the dark for a few days. The radiation from the fixed probe will produce its mark on the X-ray plate. This is called autoradiography (Fig. 55.4B). Mutant genes such as HbS, cystic fibrosis, DMD, PKU as well as presence of viral DNA (hepatitis virus B and C) can be identified by this method.

3. Northern Blotting for Identifying RNA
The Northern blot is used to demonstrate specific RNA. The total RNA is isolated from the cell, electrophoresed and then blotted on to a membrane. This is then probed with radioactive cDNA. There will be RNA-DNA hybridization. This is used to detect the gene expression in a tissue (see Fig. 55.3).

4. Western Blot Analysis for Proteins
In this technique, proteins (not nucleic acids) are identified. The proteins are isolated from the tissue and electrophoresis is done. The separated proteins are then transferred on to a nitrocellulose membrane. After fixation, it is probed with radioactive antibody and autoradiographed. Alternately, the
specific antibody is poured over, washed and a second antibody carrying horse radish peroxidase is added. Hydrogen peroxide and a chromogen are layered (Figs 55.3 and 55.4B). This technique is very useful to identify the specific protein in a tissue, thereby showing the expression of a particular gene. Southern, Northern and Western blots are compared in Figure 55.3.

5. In situ Hybridization

It allows one to examine the tissue first by microscope. It is a modified version of DNA–DNA hybridization (Fig. 55.1). If a metaphase spread chromosome preparation is probed with a gene, the location of the gene on a specific chromosome can be identified. The principle may be applied to histology slide also. In the tissue preparation, DNA is denatured, the specific probe tagged with a fluorescent label, incubated, washed and seen under a fluorescent (UV) microscope. The process is named as fluorescent in situ hybridization (FISH).

Histology section or single cells may be treated with specific antibodies tagged with fluorescence and seen under microscope (Fig. 55.5A). Histology section may be treated with antibody linked with peroxidase and color developed (Fig. 55.5B).

In situ hybridization has gained popularity over other molecular biology methods because the DNA/mRNA of interest can be viewed in the context of the tissue morphology. When the probe is tagged with fluorescein, it can be seen under UV microscope; then it is called FISH (fluorescent in situ hybridization).

Examples of applications of ISH and FISH are: (a) assessment of gene rearrangements in leukemia, (b) diagnosis of B-cell lymphoma by demonstration of reduced light-chain mRNA, (c) determination of amplification of HER2/neu in breast cancer and, (d) diagnosis of various types of lymphomas. Chromogenic in situ hybridization (CISH) is used to diagnose melanoma and lymphoma using mRNA probes for kappa and lambda chains.

6. Microarray Technique

DNA probes of about 500 to 5000 genes are prepared and added to very small wells in polystyrene plates. DNA (or cDNA) prepared from patient's tissue is added to each well, hybridized (Fig. 55.6). Fluorescence is assessed. So, the presence and expression of various genes may be identified quickly.

Animal Cloning

The term cloning has two broad meanings. When a gene of higher organism is introduced into a bacterial DNA, it is called “cloning of the gene” or molecular cloning; details of which are described in chapter 43. When a cell from an animal is grown to an exact duplicate of that animal, it is known as cloning of an animal or “somatic cloning”.

It made big news when Ian Wilmut and Keith Campbell of Scotland cloned a sheep named “Dolly” in July 1996 (Dolly died naturally in 2002, and not due to any complications of cloning). Today the sheep, tomorrow it could be the shepherd. So this raised a number of moral, ethical and legal issues.

A single adult cell contains all the genetic material for making the entire animal. In the case of Dolly, it was a cell from the udder (mammary cell).
Then, the nucleus of an oocyte was removed. Oocyte contains 1\(x_n\) genes; when zygote is formed, another 1\(x_n\) genes of the sperm are added, so zygote gets 2\(x_n\) genes. In this experiment, the nucleus of the mature cell already contains 2\(x_n\) genes. Therefore, the extra 1\(x_n\) genes are to be removed from oocyte, to avoid triploid (3\(x_n\)) status.

Next, the mammary cell and denucleated oocyte were fused. The fused cell was then implanted into the uterus of a surrogate mother, which delivered the baby in course of time.

**Applications of Cloning of Animals and Plants**

1. Animals with genetically desirable traits could be bred more efficiently, e.g. cows yielding more milk.
2. Biopharmaceuticals: By November 1998, the first goats were born, who were genetically engineered to produce milk containing antithrombin III. Any human protein could be introduced into the make up of goat or cow and get the desired protein cheaply through milk. Eggs have been genetically manipulated to produce interferon and insulin in the egg-white.
3. Cloning is successfully employed in agriculture, to propagate plants such as rubber, banana, orchids, etc. If a good yielding rubber is available, it is cloned so that, thousands of progenies of the same quality could be produced within a short time.
4. Species threatening to become extinct, could be reproduced easily. In October 2000, a cow, "Bessie" gave birth to a wild gaur calf named "Naoh". Scientists took skin cells from a dead gaur and fused them with Bessie's eggs, from which the bovine genes had been removed. In the science fiction cinema, "Jurassic Park", scientists produced dinosaurs; it is quite improbable in actual life; but not impossible.

**Disadvantages of Cloning**

Cloning will never replace selective breeding. Cloning halts any further progress. Cloning can produce the animals/plants with the same characteristics; new characteristics could not be developed. The cloned animal and parent need not be exactly identical. First, mitochondrial DNA invariably comes from the egg. Second, DNA in an adult cell differs from the DNA in a fetal cell by the accumulated damages of a life time. Thirdly, any animal is not just the product of its genes, but also of its environment, both in utero and after birth; this is especially so when higher organisms are concerned.

**Applications of Molecular Cloning in Medicine**

1. **Diagnosis of Genetic Diseases**

   Various genetic diseases can be identified by using appropriate probes from defective genes. A **point mutation may destroy or create a restriction enzyme cleavage site**. Then the fragment size produced from normal gene and mutated gene will be different. This can be easily identified by Southern blot.

   i. **Sickle cell anemia** is caused by a point mutation. In the beta chain of the hemoglobin, the 6th amino acid normally is glutamate. In the sickle cell anemia, this is altered to valine. In the DNA, this is seen as a change from normal T replaced by abnormal A nucleotide (T to A substitution). The normal gene has the following nucleotide sequence.

   
   ```
   CC ↓ TGA... Coding strand
   Normal HbA GG ACT ↓ CC.... Template strand
   ```

   The arrows indicate the cleaving site for the restriction enzyme Mst-II. In the sickle cell anemia gene, the underlined T is replaced by A, and the DNA sequence is as follows:

   ```
   CC TGT GG Coding strand
   HbS gene GG ACA CC Template strand
   ```

   This alteration in base sequence abolishes the recognition site for this RE. But other Mst-II cleavage sites are preserved.

   Therefore, incubation of DNA from AA (normal HbA), heterozygous AS (Sickle cell trait) and homozygous SS (Sickle cell disease) individuals fall into 3 different patterns in Southern blot technique (Fig. 55.7). The mutation eliminates one restriction site for Mst II enzyme, and hence a larger fragment is present in sickle cell anemia.

   This becomes useful as a diagnostic test for the presence of the disease allele in heterozygotes (carriers) or individuals in which the disease has not yet been manifested. Such a test is possible for **prenatal diagnosis** also. DNA from cells collected from amniotic fluid can be used for Southern blot analysis.

   ii. **Huntington's chorea** is a recessive condition. Symptoms usually begin around the age of 40, with involuntary jerky movements and muscle rigidity. Short arm of chromosome 4 codes for a normal protein "Huntington"; gene is named as IT-15. Diagnostic DNA test for this abnormal gene is now available.

   iii. **Duchenne muscular dystrophy** (DMD) is a degenerative disease of muscle affecting only male children. The gene is in the middle of the short arm of X-chromosome. This gene produces a protein called dystrophin with 3700 amino acids. It is one of the largest human genes known. In DMD patients, the gene for dystrophin is mutated. This could be identified by using a **cDNA probe** for dystrophin. In the Southern blot analysis, the fragment corresponding to this gene will be absent.
2. Detection of Specific Sequences
By using a virus probe, the presence of viral genes in the host cells can be detected. An oncogene probe will demonstrate the activation of the gene in malignant tissues.

3. DNA Finger Printing in Forensic Medicine
There are tandem repeats (TR) in chromosomes. These are short sequences of DNA, located at scattered sites. The number of these repeat units varies from person to person, but is unique for a particular person. Therefore, it serves as a molecular fingerprint. It is also known as DNA profile. Probability of similarity between two persons is only 1 in $3 \times 10^{10}$ persons.

DNA probes have been developed, so that at low stringency, they hybridize to a number of these loci to produce individual specific fingerprint. The technique is used to pinpoint the culprit of the crime, and also in disputes of parenthood. DNA can be isolated from stains on clothing made of blood or semen stained even several years before. Sperm nucleic acid can also be separated from vaginal swabs of rape victims.

Restriction Fragment Length Polymorphism (RFLP)
The human genome contains hundreds of variations in base sequences that do not affect the phenotype. The property of the molecules to exist in more than one form is known as polymorphism.

Difference in mutation and DNA polymorphism: If more than 1% of the population has a particular alteration in the sequence, it is polymorphism. If only a few individuals have it, then it is mutation. Polymorphism is normal variation, and generally having no deleterious effect. Mutation is abnormal, and sometimes will have defective function, e.g., phenyl ketonuria.

A polymorphic gene is one, in which the variant alleles are common in more than 1% of the total population. The existence of two or more types of restriction fragment patterns is called restriction fragment length polymorphism (RFLP). This can be used as a genetic marker.

DNA is treated with restriction enzymes, which cleave DNA into fragments of defined lengths. Then electrophoresis is done in agarose gels, when the fragments are separated. Finally, the DNA from the agarose gel is transferred on to nitrocellulose paper (Southern blotting) and hybridized with labelled probe sequences. Genotypic changes can be recognised by the altered restriction fragments.

Clinical Applications of RFLP
1. An individual who is heterozygous for a polymorphism has a sequence variation in the DNA of one chromosome and not in the DNA of the companion chromosome. In such cases, each chromosome can be traced from parent to offspring by the presence or absence of this marker. This is thus useful in disputed parenthood.

2. RFLP is also useful in human population genetics, geographical isolates and comparison of genetic make-up of related species.

3. Genetic diseases will produce alteration in size distribution of RE fragments, and show RFLP; examples are shown in Figure 55.7.

POLYMERASE CHAIN REACTION (PCR)
Kary Mullis invented this ingenious method in 1989, who was awarded Nobel prize in 1993. PCR is an in vitro DNA amplification procedure in which millions of copies of a particular sequence of DNA can be produced within a few hours. It is like xerox machine for gene copying.

The flanking sequences of the gene of interest should be known. Two DNA primers of about 20-30 nucleotides with complementary sequence of the flanking region can be synthesized. The reaction cycle has the following steps:

Step 1: Separation (Denaturation): DNA strands are separated (melted) by heating at 95°C for 15 seconds to 2 minutes (Fig. 55.8).

Step 2: Priming (Annealing): The primers are annealed by cooling to 50°C for 0.5 to 2 minutes. The primers hybridise with their complementary single stranded DNA produced in the first step.

Step 3: Polymerization: New DNA strands are synthesized by Taq polymerase. This enzyme is derived from bacteria Thermus aquaticus that are found in hot springs. Therefore the enzyme is not denatured at high temperature. The polymerase reaction is allowed to take place at 72°C for 30 seconds in presence of dNTPs (all four deoxy ribonucleotide triphosphates). Both strands of DNA are now duplicated (Fig. 55.8).

4. The steps of 1,2 and 3 are repeated. In each cycle, the DNA strands are doubled. Thus, 20 cycles provide for 1 million times amplifications. These cycles are generally repeated by automated instrument, called Tempcycler.

5. After the amplification procedure, DNA hybridization technique or Southern blot analysis with a suitable probe, shows the presence of the DNA in the sample tissue.

Clinical Applications of PCR
1. Diagnosis of bacterial and viral diseases: In early phases of tuberculosis, the sputum may contain only very few tubercle bacilli, so that
usual acid fast staining may be negative. But PCR could detect even one bacillus present in the specimen. Any other bacterial infection could also be detected similarly. The specific nucleotide sequences of the bacilli are amplified by PCR and then detected by Southern blot analysis. If reverse PCR is done, living organisms could be detected. This technique is widely used in the diagnosis of viral infections like Hepatitis C, Cytomegalo virus and HIV.

2. **Medicolegal** cases: PCR allows the DNA from a hair follicle or a blood cell to be analyzed. The restriction analysis of DNA from the hair follicle from the crime scene is studied after PCR amplification. This pattern is then compared with the restriction analysis of DNA samples obtained from various suspects; the culprit’s sample will perfectly match with that of PCR amplified sample. The restriction analysis pattern of DNA of one individual will be very specific (DNA fingerprinting); but the pattern will be different from person to person. This is highly useful in forensic medicine to identify the criminal.

3. **Diagnosis of genetic disorders**: The PCR technology has been widely used to amplify the gene segments that contain known mutations for diagnosis of inherited diseases such as sickle cell anemia, beta thalassemia, cystic fibrosis, etc.

4. PCR is especially useful for **prenatal diagnosis** of inherited diseases, where cells obtained from fetus by amniocentesis are very few.

5. **Cancer detection**: PCR is widely used to monitor residual abnormal cells present in treated patients. Similarly identification of mutations in oncosuppressor genes such as p53, retinoblastoma gene, etc. can help to identify individuals at high risk of cancer (oncogenes and oncosuppressor genes are described in Chapter 51).

6. **Fossil studies**: DNA can be isolated and PCR amplified from fossils and is used to study evolution by comparing the sequences in the extinct and living organisms. See also Box 55.2.
Reverse Transcriptase PCR (RT-PCR)
It is the method used to amplify, isolate or identify a known sequence from a cell or tissue RNA library. Essentially normal PCR is preceded by reverse transcription (to convert the RNA to cDNA). This is widely used in expression mapping, determining when and where certain genes are expressed. Instead of Taq polymerase described above, Tth polymerase from *Thermus thermophilus* may be used. This enzyme has both DNA polymerase and reverse transcriptase activities at high temperature. This allows both cDNA synthesis from mRNA followed by PCR amplification. In ordinary PCR, DNA is detected; that DNA could be from a living or nonliving organism. But in reverse PCR, mRNA is detected; that means, it is derived from a living organism. Presence of HIV RNA in blood can be detected as early as 4 weeks after infection.

Nested PCR
Nested PCR is intended to reduce the contamination in products due to the amplification of unexpected primer binding sites. Two sets of primers are used in two successive PCR runs, the second set intended to amplify a secondary target within the first run product. This is very successful, but requires more detailed knowledge of the sequences involved.

Real Time PCR
By this method, quantitation of the number of virus present in a sample can be calculated, e.g., viral load in HIV or HBV. So, the treatment modalities can be planned and the response to treatment could be assessed.

Quantitative PCR
Q-PCR (Quantitative PCR) is used to rapidly measure the quantity of PCR product (preferably real time), thus is an indirect method for quantitatively measuring starting amounts of DNA, cDNA or RNA. This is commonly used for the purpose of determining whether a sequence is present or not, and if it is present the number of copies in the sample.

Quantitative Real time PCR (RQ-PCR)
This methods use fluorescent dyes, such as Sybr Green, or fluorophore containing DNA probes, such as Taq Man, to measure the amount of amplified product in real time.

RACE-PCR
RACE, or Rapid Amplification of cDNA Ends, is a technique used in molecular biology to amplify the ends of messenger RNA (mRNA) transcripts using a specialized reverse transcription-polymerase chain reaction (RT-PCR). It allows the amplification of an unknown end portion of a transcript using known information from the center of the transcript. It can be used to obtain the 5' end (5' RACE-PCR) or 3' end (3' RACE-PCR) of mRNA. This technique is sometimes called one-sided PCR or anchored PCR.

Multiplex-PCR
The use of multiple, unique primer sets within a single PCR reaction to produce amplicons of varying sizes specific to different DNA sequences. By targeting multiple genes at once, additional information may be elicited from a single test run that otherwise would require several times the reagents and technician time to perform. Annealing temperatures for each of the primer sets must be optimized to work correctly within a single reaction and amplicon sizes should be separated by enough difference in final base pair length to form distinct bands via gel electrophoresis.

Hybridoma Technology and Monoclonal Antibodies
1. Differences between monoclonal and polyclonal antibodies
If an antigen is injected into an animal, the animal produces different types of antibodies against various epitopes of the antigen. The antibodies thus generated are polyclonal in nature. Different molecules will have different specificities and affinities (Fig. 55.9). In all microbial infections, body reacts with polyclonal antibody production.

However, in nature, monoclonal antibodies are produced in multiple myeloma where only one clone secretes a particular type of antibody (Chapter 49). But in multiple myeloma, the antibody thus generated is unwanted.

In the laboratory, monoclonal antibody can be generated. In this case, only a particular type of antibody against a specific epitope of the antigen is produced (Fig. 55.9). Monoclonal antibodies...
were first produced by Georges Kohler and Cesar Milstein in 1975. They were awarded Nobel prize in 1984.

2. Production of Hybridoma
   i. The antigen is injected into mice.
   ii. Spleen cells from the immunised mice are fused with mice myeloma cells, so as to produce a hybrid cell. Polyethylene glycol (PEG-1500) is used as a fusion agent.
   iii. The hybrid cells now contain the gene of normal mice as well as the myeloma cells. (Fig. 55.10).
   iv. However, hybridization might have occurred between two normal cells. Normal cells lack in the multiplication potential. So all the hybridised normal cells die in the usual culture conditions within 5-6 days.
   v. The myeloma cells are defective in the enzyme HGPRTase and so they lack the salvage pathway for DNA synthesis. In the culture, HAT medium is used containing hypoxanthine, aminopterine and thymidine. The aminopterine, a folic acid antagonist, will inhibit the de novo synthesis of DNA. Since both pathways are blocked, the unfused myeloma cells also die in the special medium provided.
   vi. The only cells that survive are the cells where fusion has taken place between normal spleen cells with myeloma cells. In this case, normal cells provide the HGPRTase enzyme and so DNA synthesis is possible from the hypoxanthine and thymidine provided in the medium.
   vii. The normal cellular genes also provide the information for specific antibody synthesis. The myeloma cancer genes provide the endless multiplication drive, so that hybrid cells are immortalized (Fig. 55.10).

3. Applications of monoclonal antibody
   a. Enumeration of lymphocyte subpopulations.
   b. Quantitative preparation of specific cells
   c. As immunosuppressant in clinical conditions
   d. Nephelometric assays of blood components.
   e. To do ELISA tests.
   f. Quantitative preparation of pure antigens.

4. Advantages of monoclonal antibody
   In a monoclonal preparation, all the antibody molecules are specific against a particular antigen.

---

Fig. 55.10. Principle of production of monoclonal antibodies by hybridoma technique. Myeloma cells propagated in mice ascites. Immunise normal mice with specific antigen. Immune spleen cells and myeloma cells are fused with the help of PEG-1500. The cells are incubated in HAT medium. Unfused lymphocytes will die as they do not have the proliferation capacity. Unfused myeloma cells lack in HGPRT gene, so alternate pathway for DNA synthesis is not available. The main pathway for DNA synthesis is blocked by aminopterine in the HAT medium. So, unfused myeloma cells die. Only fused cells can grow in HAT medium. Some of the wells contain the hybridoma cells secreting the specified antibody. The supernatant in each well is tested for the presence of antibody. Those wells containing the antibody, and selected further. The useful hybridoma cells can be cultured in vitro in culture flasks or in vivo as mice ascetic fluid. Indefinite amount of monoclonal antibodies could be harvested.
They have increased avidity for attaching with antigen. So in a reaction where polyclonal antibodies require 1 ml, the monoclonals require only microliter quantity. The initial cost for production is high; but when once produced, it could be harvested continuously. Because of these advantages, more and more monoclonal antibodies are now commercially produced. These are highly useful to detect (a) serum proteins, (b) enzymes, (c) hormones, (d) drugs, (e) bacterial antigens (f) viral antigens, (g) cell surface receptors, (h) HLA antigens, (i) and cancer antigens.

MUTATION DETECTION TECHNIQUES

Single Strand Conformation Polymorphism (SSCP)
SSCP analysis involves the heat denaturation of PCR-amplified DNA followed by electrophoresis under non-denaturing conditions. The fragments are visualized by radiolabeling and autoradiography. A variety of nonisotopic methods are now available, including fluorescent labels, and ethidium bromide staining. The SSCP technique relies on the propensity for single stranded DNA (ssDNA) in non-denaturing conditions to take on a three-dimensional, or secondary, structure that is highly sequence dependent. Consequently, sequence differences can cause alterations to the DNA's secondary structure as well as in electrophoretic mobility (see Fig. 55.11). The optimum sensitivity of SSCP is with fragments as small as 150 bp, where under a single condition, 90% of mutations are detected.

Heteroduplex Analysis
Heteroduplexes are hybrid DNA molecules that, although largely matched, have one or more mismatched base pairs. Heteroduplexes have been used as a tool to scan for point mutations. They typically appear on native polyacrylamide gels as one or two bands of reduced mobility relative to the homoduplex DNA. Heteroduplexes have been visualized using radioisotopes, silver staining, and ethidium bromide staining. The detection efficiency of heteroduplex analysis has been reported to approach 90% under ideal conditions and the optimum size, 250-500 bp.

Combined SSCP/heteroduplex analysis exploits the features of both. The gel conditions for both SSCP and heteroduplex analysis are compatible and so it is possible to get “two techniques for the price of one”.

Conformation Sensitive Gel Electrophoresis (CSGE)
The advantages of CSGE are (1) High sensitivity – More than 99.9% of single base mutations can be detected. (2) Less costly, compared to DNA sequencing. (3) Larger fragments can be analyzed. Conventional SSCP can detect mutations in fragments in the 150-350 bp size range. However, CSGE can be used to detect mutations in up to 500 bp PCR fragments.

Single base mismatches produce conformational changes in double stranded DNA, which leads to differential migration of heteroduplexes and homoduplexes. The gel contains partially denaturing agents, in the form of formaldehyde and ethylene glycol, the conformational changes produced in the first instance get increased further, leading to a clear separation of the heteroduplex bands. Therefore, a normal sequence will give a homoduplex band corresponding to normal DNA, whereas mutant DNA can give theoretically up to 4 bands (see Fig. 55.12).
Protein Truncation Test (PTT)

It is also referred to as the in vitro synthesized-protein assay (IVSPA). This is a method for screening the coding region of a gene for mutations that result in the premature termination of mRNA translation. The polymerase chain reaction (PCR) is used to amplify a DNA template, usually of 1-3 kb in size, that is tested in an in vitro transcription and translation assay. Truncated proteins are identified by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) and autoradiography or fluorography. The complete coding sequence of a large gene, with many small exons, can be amplified in several overlapping fragments by reverse-transcription PCR (RT-PCR). Amplifying the gene in several segments that overlap each other by 300-500 bp increases the sensitivity of protein truncation test. A truncating mutation located toward the 3' end of one segment will also occur near the 5' end of the next overlapping segment, thus increasing the likelihood of identifying a truncated protein. The size of the truncated protein indicates the position of the premature stop codon, and DNA sequencing of genomic DNA is performed to confirm the presence of a mutation (see Fig. 55.13).

There are two main advantages of PTT compared to most other mutation detection methods. Several kilobase segments of a gene can be rapidly screened in a single reaction, and PTT only identifies those mutations that have a clear pathological effect (loss of function).

Denaturing High Performance Liquid Chromatography (DHPLC)

DHPLC can be used to detect single-nucleotide substitutions or small insertions or deletions in double-stranded DNA fragments. Nucleic acids can be bound to a hydrophobic column. The affinity of this interaction is dependent on size, nucleotide composition, and column temperature. An increasing gradient of an organic solvent, usually acetonitrile, is passed over the column and gradually releases bound DNA from the column. After being eluted, the DNA can be detected by ultraviolet (UV) absorbance or, if the DNA has been labeled, by fluorescence.

Under nondenaturing conditions (double stranded DNA remains fully paired), the interaction is almost completely dependent on fragment size. At high column temperatures, double stranded DNA is completely denatured into single strands and elution from the column is dependent on both size and sequence. For most purposes, DHPLC is performed under partially denaturing conditions. DNA containing a mismatch has a slightly lower affinity for the column because it makes fewer ion-pairing bonds with the hydrophobic column and will elute before the fully paired DNA. Typically, single-nucleotide mismatches can be reliably detected in DNA fragments of 300-400 nucleotides.

Transgenesis

It is a form of germ cell gene therapy. A recombinant DNA segment, containing the desired gene from another species, is introduced into the fertilized ova. The embryos are allowed to develop in the uterus of another animal. The animals born are called transgenic animals. When growth hormone gene is introduced, the animals became twice as large as their normal counterparts. The potential applications of these findings are many. Attempts are already under way to increase milk production in cows by transgenic method. The transgenic approach has been used to correct genetically determined hypogonadism in mice. Production of biopharmaceuticals, described under the heading application of cloning of animals, is another example of transgenesis.

Fusion Proteins

A fusion protein is the product of a fusion gene. A fusion gene is produced by removing a stop codon from the DNA sequence coding for a particular polypeptide and appending the DNA sequence coding for another protein. The product is a fusion protein. Tumor cell targeted immunotherapy can use fusion proteins associated with monoclonal antibodies.

DNA Sequencing

In 1977, two sequencing techniques have been developed. Sanger's technique is based on constructing a complementary DNA (cDNA) copy of the molecule using deoxy nucleoside triphosphates (dNTPs), a specific synthetic oligonucleotide primer and a DNA polymerase. Gilbert developed the base-specific chemical cleavage method. Both were awarded Nobel prize in 1980.

Sanger's technique is called “controlled termination of synthesis”; it uses chain terminating agents. Suppose the sequence of the polynucleotide is 3'AACCTGAGTA5'. This DNA sample is taken in 4 different test tubes (Fig. 55.14). In all tubes, the Klenow enzyme (DNA polymerase without exonuclease activity) and radiolabelled TT as the primer are added. In all tubes radioactive dNTPs (all the 4 nucleotides which are labelled with 32P) are added. Synthesis of a new
strand of DNA having a sequence of 5’ TTGAGCTCAT3’ is started. But in the first test tube, ddTTP (2’,3’-di deoxy TTP) is also added. The ddTTP will add the T, but it cannot form the next phosphodiester link, and so further chain lengthening is stopped. In other words, ddTTP will stop chains at T. Instead of ddTTP, the polymerase might add a normal dTTP, in which case chain growth will continue till the next T. Thus in first test tube, TTGAGCT (7 nucleotides) and TTGAGCTCAT (10 nucleotides) are produced.

In the second test tube, ddATP is added, so chain length is stopped at A. So in the 2nd tube, DNA strands having sequences of TTGA (4 nucleotides) and TTGAGCTCA (9 nucleotides) are produced. Similarly, in the 3rd test tube, ddCTP is added, which will contain TTGAGC (6 nucleotides) and TTGAGCTC (8 nucleotides). In the 4th tube containing ddGTP will have TTG (3 nucleotide) and TTGAG (5 nucleotides).

Then the contents of each tube are simultaneously examined on polyacrylamide electrophoresis. The position of these fragments will correspond to the chain length; e.g. chain with 10 nucleotides will move least, while with 3 nucleotide will move maximum and other nucleotides will be arranged in their order of molecular size. The gel is then auto-radiographed. The radiation from 32P labelled primer will be available in all pieces and will be seen as dark bands in the X-ray plate (Fig. 55.14). From the picture, it can be inferred that 7th and 10th bases are T. Similarly the positions of other bases can also be deciphered. Thus the sequence of the newly synthesized strand is known. The complementary sequence will be present in the original unknown DNA.

### Bioinformatics

In a broad perspective, bioinformatics describes **any use of computers to handle biological information**. Bioinformatics may be regarded as a synonym for “computational molecular biology”. It is the use of computers to characterize the molecular components of living things. It can be applied to store, retrieve, analyze or predict the composition or the structure of biomolecules. A more compact working definition would be: “A summation of all mathematical, statistical and computing methods that aim to solve biological problems using DNA and amino acid sequences and related information.” According to this scheme, the monomers in a given macromolecule of DNA or protein can be treated computationally as **letters of an alphabet**, put together in preprogrammed arrangements to carry messages or do work in a cell.

Bioinformatics embraces Computational Biology, Mathematical Biology, Pharmacogenomics, Proteomics, Genomics, Biophysics, Medical Informatics and Chem-informatics.

### Applications of Bioinformatics

A lot of bioinformatics work is concerned with the technology of databases. These databases include both “public” repositories of gene data like GenBank or the Protein DataBank (the PDB). Databases of existing sequencing data can be used to **identify homologues of new molecules** that have been amplified and sequenced in the lab. The property of sharing a common ancestor, **homology**, can be a very powerful indicator in bioinformatics.

Bioinformatics can be used to obtain sequences of **genes or proteins of interest**, either from material obtained, labelled, prepared by individual researchers/groups or from repositories of **sequences** from previously investigated material.

Sequence analysis can be done by three ways: 1. They can be **assembled**. 2. They can be **mapped**. 3. They can be **compared** for their homologous nature with sequences already existing in the database. If a homologue (a related molecule) exists, then a newly discovered protein may be modeled, that is, the three dimensional structure of the gene product can be predicted without doing laboratory experiments.

Bioinformatics is used in **designing primers for PCR**. It is also used to attempt to **predict the function** of actual gene products. There are tools which allow making **predictions** of the secondary structure of proteins arising from a given amino acid sequence. Structural biologists use “bioinformatics” to handle the vast and complex data from X-ray crystallography, nuclear magnetic resonance (NMR) and electron microscopy investigations and create the 3-D models of molecules.

Bioinformatics embraces Computational Biology, Mathematical Biology, Pharmacogenomics, Proteomics, Genomics, Comparative Genomics, Biophysics, Medical Informatics and Chem-informatics.

### Nanotechnology

Nanotechnology is an exciting new science which deals with miniaturization of devices and processes at the nanometer (10^9 m) scale. To give an idea, human hair varies from 18 to 180 micrometers. Thus nanotechnology is working at a level 100-1000 times smaller than human hair. Nanotechnology is the science for understanding and control of matter at dimensions between 1 and 100 nanometers. Nanotechnology involves imaging, measuring, modeling, and manipulating matter at nano scale, applicable to both engineering and medicine. Unusual physical, chemical, and biological properties can emerge in materials at the nanoscale. Richard Feynmann (1918-1988) is considered to be the father of modern nanotechnology. The word “nanotechnology” was coined by Norio Tanigushi (1974). It can be said that
nanotechnology is a marriage of medicine and engineering disciplines. Many tools of nanotechnology are derived from biotechnology and have wider applications in medicine. When nanotechnology is used for biotechnological advances it is known as nanobiotechnology.

Bionanotechnology applications in medicine are very wide and include in the field of AIDS, cancer, gene therapy and drug delivery. Instruments like Atomic Force Microscope (AFM) and Scanning Tunnelling Microscope (STM) are currently available which allow visualization at nanometer range. Biodegradable nanomaterials, nanocosmetics, fabrics etc are also using nanotechnology principles. In nature, the hanging of geckos (small lizards) from the rooftop and the folding of the flowers of touch-me-not plant are said to be based on nanobiology. Every square millimeter of a gecko’s footpad contains about 14,000 hair-like setae. Each seta has a diameter of 500 nanometers. Because of this special adaptation of Geckos can adhere to most surfaces without the use of liquids or surface tension.

1. Drug Delivery
Nanoparticles could be used to deliver drugs to specific types of cells (such as cancer cells). Particles are attracted to diseased cells, which allow direct treatment of those cells. This technique reduces damage to healthy cells in the body and allows for earlier detection of disease. The drug to be administered is encapsulated in a nanoparticle which helps it pass through the stomach to deliver the drug into the bloodstream. Efforts are underway to develop oral administration of several different drugs using a variety of nanoparticles.

2. Therapeutics
Nanoshells may be used to concentrate the heat from infrared light to destroy cancer cells with minimal damage to surrounding healthy cells. Nanoparticles, when activated by X-rays, generate electrons that cause the destruction of cancer cells to which they have attached themselves. This is intended to be used in place radiation therapy with much less damage to healthy tissue. Aluminosilicate nanoparticles can quickly reduce bleeding time in trauma patients by absorbing water, causing blood in a wound to clot quickly. Nanofibers can stimulate the cartilage production in damaged joints.

3. Imaging Techniques
Quantum Dots (qdots) may be used in the future for locating tumors in patients and for performing diagnostic tests. The nanoparticle is coated with a peptide that binds to a cancer cell, once the nanoparticles are attached to the tumor the magnetic property of the iron oxide enhances the images from the Magnetic Resonance Imaging scan. Nanoparticles can attach to proteins or other molecules, allowing detection of disease indicators in a sample at a very early stage.

4. Antimicrobial Techniques
One of the earliest nanomedicine applications was the use of nanocrystalline silver which is an antimicrobial agent for the treatment of wounds. The nanoparticles containing nitric oxide gas are known to kill bacteria.

5. Cellular Repair
Nanorobots could be programmed to repair specific diseased cells, functioning in a similar way to antibodies in our natural healing processes.

6. Aquasomes
These are recently developed delivery systems that are making a niche as the peptide/protein carriers. These are nanoparticle carrier systems with three layered self-assembled structures. They comprise the central solid nanocrystalline core coated with polyhydroxy oligomers onto which biochemically active molecules are adsorbed. The solid core provides the structural stability. The carbohydrate coating acts as dehydroprotectant and stabilizes the biochemically active molecules. Due to this property of maintaining the conformational integrity of bioactive molecules, aquasomes are being proposed as a carrier system for delivery of peptide based pharmaceuticals. The delivery system has been successfully utilized for the delivery of insulin, hemoglobin and various antigens. Oral delivery of enzyme peptidase has also been achieved.
